SIR WILLIAM TURNER THISELTON-DYER,

DIRECTOR OF THE ROYAL GARDENS, KEW.

THE FIFTY-SEVENTH VOLUME OF "THE GARDEN"

Is dedicated.

BORN in 1843, Sir William Thiselton-Dyer became, forty-three years later, Director of the Royal Gardens, Kew, in succession to his father-in-law, Sir Joseph Hooker. In his earlier years Sir William took honours in Mathematical and Natural Science at the universities of Oxford and London, and held the Professorship of Natural History and of Botany successively at the Royal Agricultural College at Cirencester and the Royal College of Science for Ireland, entering on his work at the Royal Gardens as Assistant Director in 1875. As Professor of Botany and of Natural History, as lecturer to classes of teachers in training, as President of more than one section, on different occasions, of the British Association, as Vice-President of the Royal Society, as Member of the Senate of the London University and in other allied offices, he has already done a life's work of steady labour in botany.

In botanical literature Sir William published in 1865, with the late Dr. Trimen, *A Flora of Middlesex*, for which the collection of material was begun in school days, and in 1875 edited the English edition of *Sachs's Pocket-book of Botany*, and is now engaged in editing the *Icons Plantarum*, and the continuation of the *Flora Capensis* and the *Flora of Tropical Africa*.

Since his appointment to the Directorship of the Royal Gardens, Sir William has laboured with conspicuous success to the perfecting of their scientific organisation. The Gardens now contain 20,000 species and marked varieties, and these are nearly all catalogued in a series of hand-lists, which are generally accepted as authoritative standards of botanical nomenclature. The Director is now mainly occupied with the organisation of botanic establishments in India and the colonies and in training men for their service. The labour entailed by these works, besides that of advising the Government on technical questions and the constant pressure of an immense and important correspondence, must be more than enough for a man who has all his life had to struggle with indifferent health.

But in addition to his earnest and arduous labours in botanical science and organisation, all who have delight or interest in horticulture owe an immense debt of gratitude to the Director of the Royal Gardens, in that he has so raised their horticultural standing as to have made them a living exposition of a vast collection of plants so grown and arranged as to make the Gardens a place of beauty and of the highest instructive value in gardening, of a kind that may be understood, not only by the owners of large places, but by those who are holders of the tiniest plot of ground.

INDEX.

A.

Acaecia dealbata, 45; Drummondii, 148; in California, 173; *obliqua*, 345
Acalypha hispida, 42
Achillea tomentosa, 196
 Aconite, Winter, and Siberian Dogwood, 124; Winter not flowering, 169, 208
Ada aurantiaca, 250
Adonis amurensis, 90
Agapetes hexifolia, 172
Agathaea coelestis, 196
 Agricultural packing at Rome, exhibition of, 300
Akebia quinata, 474
 Alexandra Palace and Park, the, 376
 Almost a Centenarian, 91
 Alpine garden, *Primula viscosa* in, 311
 Alpines, some May-flowering, 461
Althaea ficifolia, 3
 Anaryllises at Chelsea, 284
Amelanchier florida, 417
 American notes, 194, 259, 274, 297, 319, 355; plants and seeds, notes on new and rare, 235
Amorphophallus titanum, 68
Anacyclus formosus, 436
Anchusa Barrelieri, 455; *italica grandiflora*, 471
Andromeda japonica, 448
Androsace carnea, 286
Anemone, *blanda synthinnica*, 286; blue wood, 2, 4, 319, 323, 369; *conopsea* and *A. hortensis*, forms of 199; *Dilgens bicolor*, 377, 406; King of Scarlets, 131; King of Scarlets from Lincoln, 433; *nemorosa robinsoniana*, 362; *ramunculoides*, 393, 497, 428, 449; *robinsoniana* in Ireland, 392; *vernalis*, 374; Wild, 238
Anemone, the St. Brigid, 474
Anoanthus breviflorus, 248
Anopterus glandulosa, 148
Anthericum algerense, 455
Antholyza aethiopica, 43; *coccinea*, 455
Aphelebia nitens, 42
 Apple trees, pruning, 483
 Apples, an election, 413; best for Britain, 195, 249, 309, 346, 286; choice preservation of, 175; Cackle Pippin, 8; Cox's Orange Pippin, 409; growing from cuttings, 197, 259; injured by hail, 56; in Warwickshire, 44; late, 127; Lord Burghley, 368; Mrs. Leopold de Rothschild, 34; Nancy Jackson, 185; notes on, 259; the best, 388; thinning, 472; too many kinds of, 153; tree, bush, 34; upon walls, 127, 259; very late in Scotland, 429; well kept, 412
 Apples and Pears, 89
 Aquatics in America, 355
Aquilegia Scutell, 455
Aquilegia and their hybrids, 398

THE GARDEN.

No. 1468. VOL. LVII.]

[JANUARY 6, 1900.

A WINTRY PICTURE.

Now in the woodlands from the creaking boughs
The last sere leaves are loosened and unstrung,
Where once the tender honeysuckle ching,
And the fond mavis fluted to his spouse,
Already dreaming of her winter drowse,
And brooding dimly on her unborn young,
The dormouse rakes the beechmast, and among
The matted roots the moldwarp paws and
ploughs,
Over the furrows brown and pastures gray
The melancholy plovers flap and plain;
And, along shivering pool and sodden lane,
As lower droop the lids of dying day,
Like to a disembodied soul in pain,
The homeless wind goes wailing all the way.

ALFRED AUSTIN.

TO OUR READERS.

WITH the present issue, *THE GARDEN*, under new ownership and direction, enters upon another period of its existence.

During the twenty-eight years through which it has reflected the thought and intention of its founder, it has been the instrument mainly employed for the furthering of the object to which the best years of his life have been devoted. This object has been to promote the knowledge of the better ways of horticulture, and to give to all who would garden well in the temperate world, a clear knowledge of beautiful plants and shrubs and trees, and of the best ways of using them. That such helpful instruction was much needed has been proved by the eagerness with which it has been accepted, while its clear result is shown in the widespread and intelligent interest now taken in matters horticultural.

And although the newer and better ways of gardening are only a return to those of our ancestors, yet the precious heritage they left us had for many years been lost. To have been the means of restoring it, and also to have awakened many more minds to the knowledge of the happiness that may be found in a garden, is an achievement of which any one man may well be proud. The benefit is one which is not only individual, but national. Indeed, it is probable that, during the century of extraordinary progress upon whose last year we are now entering, no movement that has been kindled into life has had so direct a bearing upon the happiness of so large a number of people.

When, towards the close of the year 1871, Mr. Robinson founded *THE GARDEN*, the good hardy border flowers, beloved of our ancestors,

had long been banished, and the bedding system, in the wearisome monotony of its all-prevailing practice, was almost the only expression of gardening existing throughout the country. It was a bondage of fashion, spreading from end to end of the land, that had even in many cases driven the good old border flowers out of the little cottage plots. Mr. Robinson set himself the task of combating this evil, and of restoring to favour the simple and delightful ways of the older gardening, that for so many years had been thrust aside. There can be no doubt that it is mainly owing to his work and influence that our gardens have regained their ancient and most precious character of peace and beauty, and power of giving happiness.

The love of beautiful flowers and of gardening is deeply rooted in the heart of the English people, and the remarkable evidence of the reawakening of its latent vigour that has taken place during late years, shows how gladly and gratefully people have seized upon the opportunities that have once more been placed within their reach.

It is not only in private gardens, great and small, that the wholesome change has been wrought. The present Director of the Royal Gardens at Kew was quick to apprehend the importance of the movement, and to appreciate its value as a means of national education. And now at Kew the intentional pictorial treatment of tree and shrub and flower adds a new and vast range of instructive teaching to an already magnificent scientific establishment; moreover, following this good example, the curators of Botanic Gardens throughout the kingdom now appear to vie with each other in adding to the beauty as well as to the scientific efficiency of those that are in their charge. The great improvement in the treatment of flowers in London parks is traceable to the same good influence, while the beautiful grouping of plants, especially as in Regent's Park, has become an important means of popular instruction, both in the making of good acquaintance with ornamental vegetation and in the enjoyment of one of the best and purest of human pleasures.

We desire to strengthen all *THE GARDEN*'S good traditions. It is to be, even more than heretofore, a paper for everybody. We trust that the learned botanist and the consummate horticulturist will still give a helping hand to the amateur, who begins equipped only with his love of flowers, his honest enthusiasm, and his desire to learn; that the working gardener, whose life's

experience is beyond all value, will write of it for the good of all; that the paper will continue to be a medium of pleasant interchange of thought, suggestion, and record of practice. We earnestly request its old friends to give it, in its new life, the welcome help that has contributed in so large a measure to the building up of its present position and utility. We ask for the courteous and kindly countenance of our brethren in horticultural journalism, and especially for that of our older and graver contemporaries. We also desire that our friendly relations with all the branches of horticultural trade may not only be to their own benefit, but may enable us to co-operate with them to the working out of the many matters that bear upon the best and worthiest aspects and interests of gardening.

So it is that we take up the work of *THE GARDEN*; remembering the long labour and wealth of solid material that have gone to its making; ever mindful of the clear purport of its teaching, that has won it honour from the beginning; looking forward with good courage to gaining for it an ever-widening field of usefulness, and working onward with the determination to build well and soundly upon its firm foundation.

THE EDITORS.

CHRISTMAS ROSE (HELLEBORUS ALTIFOLIUS),

which usually commences to bloom towards the close of October, is, for the most part, past its best by Christmas-tide, but its place is taken by the chaste St. Bridget's Christmas Rose (*H. javernis*), with its capped blossoms and pale green stems, the Riverston and Bath varieties, and the handsome Madame Fourcade. The flowers of the Christmas Rose often remain uninjured, in a dormant condition, through a spell of severe frost. During the bitter cold that marked the opening months of 1895 some partially-expanded blooms and buds of varieties of *Helleborus niger* were caught by the frost in the first week of January and remained frozen on the ground until the month of March was well advanced and the long-deterred thaw set in. As the frost relaxed its grip the flowers gradually assumed an erect position and continued their abnormally delayed expansion unharmed. The gold of the Winter Jasmine (*J. nudiflorum*) lights up many a southern wall and cliff face, and is particularly charming when associated with the crimson of the beautifully variegated *Cotoneaster microphylla*. On not a few houses the Passion Flowers still display their oval orange fruits beneath the sheltering eaves, and the Winter Sweet (*Chimonanthus fragrans*) diffuses on the air its delicate perfume. Some of the earlier Rhododendrons, such as *R. Nobilemum*, are already showing colour in their flower trusses, and in positions screened from the effects of the frost a few Violets are to be found.

"THE GARDEN."

IT is written on the first page of the first volume of THE GARDEN, sent to me by my friend the Editor:

"My dear Mr. Hole. We talked one day in Regent's Park of THE GARDEN before it came into existence, and on the same day gave it its name. Kindly accept the first volume as a small token of my deep gratitude for the great help you gave me, in endeavouring to conduct it safely through the first and most difficult year of its life. Always yours, WILLIAM ROBINSON, November 29, 1872."

I had retired with my friend from the heat of the Exhibition tents when he first announced, as we sat, *subtequino fagi*, his intention to edit a weekly newspaper exclusively devoted to horticulture. At that time there was only one hebdomadal publication on the subject which kept within the boundaries of the garden, and this, the *Gardener's Magazine*, although it was conducted by a most zealous and capable editor, Mr. Shirley Hibberd, had not the circulation which it deserved. The *Gardener's Chronicle*, admirable then as now, and supported by a very large staff of efficient contributors, was combined with an *Agricultural Gazette*, and many of the pleasant practical pages of the *Cottage Gardener* were devoted to beehives and cocks and hens.

I therefore welcomed with acclamation Mr. Robinson's proposal to establish a newspaper which would treat of the garden and the garden only, and so far as other topics were concerned should "brook no rival near its throne."

I was impelled by stronger motives and happier anticipations to express my sympathy, and to promise such help as I could give, as I knew that my companion was resolved to maintain against all comers the superiority of the Natural to the Artificial system, of the English to the Italian, style of garden, and that he had not only the will but the power. He believed, as I believed, in Tennyson's words: "Great Nature is more wise than I."

We were troubled with sceptical notions on the subject of "bedding-out." The new toy had fascinated the childish heart, which delights in coats of many colours by day, and in fireworks by night, but the eyes began to ache and tire of the kaleidoscope.

I had been constrained to ask a gardener who grew scarlet Geraniums, yellow Calceolarias, and blue Lobelias by the acre, to take me to his kitchen garden that I might cool my organs of vision on the parsley. Hundreds of us who thought that we were gardeners had been dazzled into a serious form of ophthalmia which forgot the wise warning: "*O formose puer nitidum ne crede colori*," and had forsaken our first love, expelled in many instances our flowering shrubs and perennial flowers, so that we might entertain and admire this delicate visitor, with her hectic flush and her gaudy habiliments. We were beginning to tire of her smart full dress, "company" clothes, her perpetual *toupe*, her society manners, her changeless expression. She was too bright, if not too good, for human nature's daily food; and, as with a guest who first charms us with outward demeanour, and then bores us by imbecility of mind, we felt a strong desire that she should go.

We became exceedingly wroth, as people always are when they do foolish things. We were never tired of telling our deluded companions that they had ruined their gardens. We spoke with bitter sarcasm of the Pelargonium family in general, and of "Tom Thumb, vivid scarlet" in particular. We

attributed all the disastrous results to the malignant influence of *Coleus Verschaffeltii*, and to the satanic power of *Cerastium tomentosum*. We rushed, also, as a matter of course, into the opposite extreme. We would annihilate this bedding-out. In no place, in no form, would we tolerate this gorgeous impostor, who had robbed our gardens of so much graceful beauty, who had induced us to substitute angles for curves, uniformity for variety, gravel for grass, perishable for permanent plants, dead levels for undulating ground, scentless for fragrant flowers.

Time and experience have told us that there is no rule, be it never so golden, which is without exceptions. All who are familiar with our palaces, castles, and grand mansions, with our public buildings, public gardens, and parks, must recognise the effective ornamentation which taste and money can make by the introduction of the "movable feasts" of spring and summer flowers. They relieve with their bright colours the massive monotony of our great buildings, and, where a garden is impossible, they charm and cheer.

Only let it be distinctly understood that this form of floriculture does not make a garden. Admire it as much as you please; when you see it with terraces and stairs and balustrades, and copings and statues and fountains, regard it as a picturesque combination of the architect's and florist's art, but please don't call it a garden.

A garden is not a place in which you are observed by all the dwellers in the house, by the proprietors and their guests below stairs, the housemaids in the bedrooms, the footmen in the lobbies, the children in the nurseries, by the grooms exercising in the park, or the visitors coming to call. A garden is a place of seclusion, of peaceful rest to the weary, in which joy can sing with the birds and sorrow can sigh with the summer breeze. It is a place in which children can play "I spy" and "hide and seek," instead of being continually warned by the governess to "keep on the walks." It is a place in which lovers' vows are sweet in every whispered word, but who ever heard of a proposal (except on the terrace by moonlight) in front of fifty windows of plate-glass, without a nook, or an arbour, or a garden chair?

Nevertheless, and though there was a time when, in a spirit of *reducta*, I would have stamped out every symptom of "bedding-out" as though it had been hydrophobia, I am convinced that in the surroundings to which I have referred it may be introduced with becoming effect as a peaceful adjunct to the scene, an ornamental appendage, but not a garden.

Mr. Robinson, in his *magnum opus*, "The English Flower Garden," the best book which a gardener can have in his library, has remarked that there are positions where stonework is necessary owing to the peculiar formation of the ground, but he strongly protests against masonic intrusions upon beautiful lawns; and whatever concessions he might be disposed to make where the houses were large and the boundaries extensive, he would never dignify these arrangements with the title of a garden.

As we sat under the tree, this "English Flower Garden," which now claims our grateful admiration, was only an idea in the brain of the author, to be realised by a laborious life. But I knew his mind and spirit—the spirit of Walpole, Addison, Pope, Kent, Whateley, Mason, and all our great English gardeners, and I listened with delight to his declaration of war against stucco, spirals, incongruities and shams of all denominations, proudly accepting his invitation to act as an honorary member of his staff.

He and his coadjutors—and I would include in this alliance all the writers, landscape and working gardeners, professional and amateur, who would promote the natural garden—have made great progress in the last quarter of our century. The love and cultivation of flowers in general, the interest in horticultural literature, the laying out of gardens and grounds, have rapidly increased and improved. The desire develops on every side to regard the garden as a thing of beauty and as a joy for ever, rather than the sort of thing you must have, don't you know, supplying pretty bouquets, tender peas, new potatoes, and a clean promenade on Sundays. There is a manifest decline in the mutilation of evergreen shrubs, and in the conversion of yews into poultry. The conviction grows that *naturam expellas furci tamen usque recurret*; you may shut out Nature with long straight lines and sharp angles, with brick-dust, and gypsum and iron palisades, but she will reappear round the corner and reproach you with an irresistible smile.

It is a march which must end in victory; but, like that of our armies in Africa, it is through the enemy's land. It is opposed by prejudice, ignorance, indolence, colour-blindness, grosser enjoyments. "Don't care," "haven't time," "can't afford," are the coarse, clumsy giants who would stop the way. They bellow, and they boast, and wear gaudy uniforms; but they are only half hardy, and in their contest with refinement and common-sense they are as the children of Ephraim, who turned themselves back in the day of battle. There are other adversaries, pigmies, and people of all sizes and sorts. Men and women with no taste, with bad taste, with a little good taste which should be educated, all these must be dealt with. We want leaders and teachers—object-lessons—beauty placed by the side of ugliness.

And so, when a field-marshal, after a long campaign of brave, patient, and successful service, returns from the front, still to guide with his counsel those whom he had led with his sword, and we cheer him as he lands on our more peaceful shores, the anxious question interrupts our welcome, "Who is to take his place?" Leaving metaphor, where shall we find a new editor for THE GARDEN.

The Americans affirm that in each great crisis of their history, although there did not seem before its occurrence to be any "kings of men" in their midst conspicuously qualified to overcome all difficulties, and to achieve greatness, and lead on to fortune, such a champion never failed to present himself—the right man, at the right time, and in the right place.

Assuredly we gardeners, on the present occasion, can make the same jubilant boast. We can say of floriculture as of the Phoenix, *uno arulso non deficit alter*, the throne is no longer empty, and although we cannot cry "Long live the king," all of us who have lived in the happy and glorious reign of Victoria will sing with all our heart and voice "God save the Queen."

My ideal of a perfect gardener, and therefore of a teacher best qualified to instruct others, would be one who combined the devout reverence of a Christian, the sentiments of a poet, and the accomplishments of an artist with the long experience of mental and manual work; and all who have read the records of this work in "Wood and Garden," they especially who have been privileged to see it, will anticipate with a sure confidence a grand success for THE GARDEN under the combined editorial auspices of Miss Jekyll and of Mr. Cook, her able and energetic co-editor.

S. REYNOLDS HOLE.

The Dairy, Rochester, December, 1899.

THE FLOWER GARDEN.

THE LARGE BLUE WOOD ANEMONE.

OUR common Wood Anemone in the Weald of Kent or Sussex varies but little, and we see it often exactly of the same type. But in woods in warm and gritty soils it grows more vigorously, and varies sometimes in an interesting way. Once, in the north of Ireland, I remember seeing nearly a dozen forms of it in one wood on free gritty soil. Now, this precious large Blue Wood Anemone of our gardens, which has come into cultivation within the last thirty years, is a pale blue variety of one of the larger forms of our wild Wood Anemone (*A. nemorosa*), and it was sent in the first instance from Ireland to the Oxford Botanic Gardens, where, in the time of the late Mr. Baxter, I first saw it. The blue forms of our native Anemone, like the white, vary, and one I saw wild in North Wales and plentiful is distinct from our plant. Blue forms of the Wood Anemone occur here and there both in England and Ireland, but are far rarer than the white forms, and smaller. Our present plant merits attention because it is the most precious of these native varieties, one of the most widely

spring flowers on warm banks, but it is also, where there is room enough, a lovely plant near grass walks and on the north side of trees and mounds, as in that way we can prolong the bloom in a sensible degree, for if there happens to be a few sunny days when the flower is in full bloom, and the flowers in the sun seem faded, we have still our reserve of blooms on the north side. Being a native plant, one of its charms is that, when sufficiently plentiful for the roots to be spared, it is one of the prettiest things to naturalise by mossy or grass walks, and the increase of the plant in cool soil of ordinary quality is very rapid. W. R.

ALTHÆA FICIFOLIA.

A YEAR ago one of my best garden friends gave me some seed of Hibiscus or *Althæa ficifolia*, and it is many years since a plant hitherto unknown to me has given me so much pleasure.

It is a kind of single Hollyhock, but much better than any single Hollyhock I have ever seen, for it has just that quality of grace and refinement that in these is lacking. The flowers are of a delicate texture and of a tender lemon colour, in some cases approaching white. The stem-leaves are lobed, and the 7-foot-high stems are slight and gracefully carried. From July to September it was one of the most delightful things in the garden—a plant that one could not pass without a feeling of pleasure and thankfulness. G. J.

West Surrey.

gardens already contain the majority of the things mentioned, but they are often scattered about the ground in a haphazard way, no attempt being made to bring them together in positions where their winter beauty would be most manifest, nor to give them the special cultivation they need.

SALIX (WILLOW).

Amongst the most noteworthy are the red and yellow-barked varieties of *Salix vitellina*. To see these Willows at their best they should be grown in masses near the water side. Although naturally trees (*Salix vitellina* being considered by some authorities to be no more than a variety of our native White Willow) they show the fine colours of the bark better when kept to a shrubby state by pruning. It is, of course, only the shoots of the year that are coloured, and the system of cultivation should be to obtain as many of these young shoots as possible and to get them of good length and thickness. There are some groups of these red and yellow Willows on the islands on the lake at Kew. They are pollarded hard back every year in March, the "stools" remaining 3 feet to 4 feet high. By means of this annual pruning, dense thickets of slender wands, 4 feet to 6 feet long, are obtained which during the four dullest months of the year give some of the brightest effects that can be had out-of-doors at that season.

Salix daphnoides and *S. acutifolia* can be treated in the same way. The bark of both is covered with a bluish white bloom—really a waxy secretion—and although the colour has not the warmth and attractiveness of the *S. vitellina* forms, the effect of a group of one or other of these species is very striking.

CORNUS (DOGWOOD).

The Willows are naturally best adapted for moist positions, near a lake or pond. For drier places several species of Dogwood (*Cornus*) can be used, some with red and others with yellow bark. The best of the red ones is *C. alba* and its varieties, but *C. stolonifera*, *C. Bailyi* and *C. circinata* are also red tinged with brown. There is a yellow-barked variety of *C. stolonifera* introduced recently from America, also a similarly coloured variety of *C. alba* called *flaviramea*. Both are bright and worth planting in masses for colour.

RUBUS (BRAMBLE).

The white-stemmed Brambles are also worthy of mention. There are several species that possess these blue-white stems, due, as in *Salix daphnoides*, to a waxy secretion on the bark which can easily be rubbed off. Undoubtedly the best of the group is *Rubus biflorus*—a species from the Himalaya frequently to be obtained from nurseries under the name of *R. leucodermis*. It grows 8 feet or more high, and its thorny, arching shoots are often 1 inch in diameter. The stems are biennial, flowering the second year. After fruiting they should be cut out, only the clean young wood of the year remaining. It requires generous conditions at the root to be seen at its best. Although similar in colour to *Salix daphnoides* and *S. acutifolia* it is, for the qualities under discussion, a better shrub, especially near London. It should be planted in groups consisting of not less than half a dozen specimens.

The best of the other species with whitish stems are *R. leucodermis*, *R. neglectus*, and *R. occidentalis*, all three of North American origin.

BETULA (BIRCH).

The silvery trunks of the common white Birch are amongst the most conspicuous

THE LARGE BLUE WOOD ANEMONE (*ANEMONE ROBINSONIANA*).

distributed, and best of all native Anemones, and also the best of the blue Anemones by reason of its hardiness and freedom in all soils, constant and prolonged bloom. When we compare it in this way with such very fine plants as the Apennine and Greek Anemones we are setting up a high standard; but this surpasses them in free growth, and I think, on the whole, in beauty. That beauty anybody can see in some degree from the smallest tuft fully open in the middle of a spring day, but its full charm can only be seen when we use it in quantities enough to form carpets among shrubs. In that case, even if dull weather prevents the beautiful quality of the colour of the open flowers from being seen, the effect of the large soft buds is very pretty. It is excellent for use among early

TREES & SHRUBS IN WINTER.

THE midwinter beauty of hardy trees and shrubs, especially deciduous ones, is apt to be overlooked. Yet woody vegetation at this season possesses a distinct charm. The rugged form of many trees—the Oak and Horse Chestnut—is only fully revealed then, and the delicate grace of others like the Birch is never so apparent. Nothing of its kind is more impressive than a giant Elm with its huge, rugged trunk and towering mass of branches and twigs—the fretted outline of which is unsurpassed in beauty among hardy deciduous trees. In this note, however, I wish to draw attention to those trees and shrubs conspicuous for the beautiful colour of their bark in winter. Many

features of the garden landscape at this season. Associated with dark evergreens like the Holly or Rhododendron, they give a singularly cheerful effect, especially in positions where the low rays of the winter sun can strike upon them. There are, however, other Birches with trunks even more vividly white than those of our native species. One of the most noteworthy of them is *Betula papyrifera*—the famous Canoe Birch of the forests of North America. Others equally good are *B. corylifolia* and *B. nudaifolia* (also called *B. alba costata*) from Japan. The freshly-exposed bark of *B. lutea* has a warm brownish-yellow colour, not, however, sufficiently pronounced to produce a noticeable effect. The trunks of the River Birch of North America (*B. nigra*), if not exactly handsome are peculiarly striking because of the bark peeling off in great flakes, which remain on the trunk for several years.

Other trees that deserve mention are the golden-twigged Lime (*Tilia platyphyllos aurantia*), the yellow-bark Ash (*Fraxinus Excelsior aurea*), and the variety of *Alnus incana* with red twigs (*ramulis coccineis*).

Some charming effects can be made by planting the early flowering bulbs beneath groups of shrubs with coloured bark. *Cornus alba* or *C. alba sibirica* with a carpeting of the yellow winter Aconite (*Eranthis*) makes a very pretty combination. The white-stemmed Rubus may be associated with *Chionodoxa* or *Scilla* in the same way. W. J. BEAN.

The Royal Gardens, Kew.

WOODLAND AND FOREST.

THE HARDIEST FIRS.

BY the term "Firs" is here meant any of the conifer family.

What constitutes *hardiness* in a forest tree in this country is a question that may be asked at the outset! Generally speaking, the answer would be "power to withstand our severest winters"—otherwise exposure and a low temperature. But there are other influences at work than those that prevent the healthy development of some of our forest trees, and these are neither a low temperature nor exposure, but are such as the tree cannot endure. Take the common Deodar, for example. It is now well known that the Deodar is not hardy enough to endure the enervating conditions existing in such localities as the valley of the Thames, in some places at least, or the climate of the New Forest, while it is quite at home in the coldest parts of the north of England and Scotland. The common Spruce, the Silver Fir, and the Douglas Fir are also sensitive subjects, and all the Spruces are more or less peculiar. The three named are at home anywhere in Scotland, where the rainfall is abundant and the soil moist, and are often subjected to a temperature below zero without the least injury, but in many parts of the east of Scotland and England, where the winds are keen though not strong, they will not thrive, and in some spots will hardly live. Inside of a dense wood they will grow and do pretty well, but nowhere else.

The Wellingtonia has the same peculiarities. It becomes a scarecrow in the open, in exposed situations where keen spring winds are felt, but it will grow fast in a wood. Frost has no effect upon it, but cold keen persistent east winds it cannot endure, and on not a few estates it has been discarded for these reasons. Up till now, our so-called pinetums have done little else

than lead us astray as regards the fitness of many exotic trees for this climate, as timber trees, because pinetum culture does not give the trees a fair trial. There are many species that will grow under plantation culture that will not succeed well in an open pinetum or lawn. Any species that will endure our severe winters in the open may be relied upon to succeed in a forest, but some species that endure severe cold, but do not grow fast in the open, will also pull up into a good useful pole in a wood.

Pines of the Scots, Corsican and Austrian Fir class behave very differently from the Spruces. Provided the soil is fairly well drained they are alike indifferent, comparatively, to severe frosts and cold winds. The peculiar constitutional difference between the Pine and Abies in that respect has never been explained, and I have often wondered if it was anything in the habit of the trees or the disposition of their leaves that caused the difference. *Abies Nordmanniana*, for example, has never, I believe, been known to suffer from the severest frost in this country. Yet I have seen this tree on an eastern aspect in Yorkshire suffer so severely from keen cold winds in February and March as to lose its leaves at the extremities of the branches, while the Scots Fir and Austrian Fir hard by showed no signs of injury. Probably excessive evaporation from the foliage caused by these dry winds causes the leaves to fall. None of the Spruces are good subjects for planting round the margins of woods in cold eastern aspects. They are all trees for gullies and glens and the inside of dense plantations.

The hardest Firs for any aspect are undoubtedly the Corsican, Scotch, and Austrian Firs and Larch. There may be others but I know of none that I would trust like these, and I put the Corsican first, Scots Fir second, and Austrian last. A good many years ago a long strip of these three species, with Larch and Beech, were planted on a most exposed site at the top of Wharfedale Crags, over 1,000 feet above the sea, on a poor peaty but dry soil, and the Corsican has over-topped all the others by a good bit; the Scots Fir coming next, and the Austrian last—a mere bush in fact. The long silky, fine glaucous leaves of the Corsican show that it is at home in such situations. Unfortunately, a fire from the railway, extending a mile from the point of origin, almost completely destroyed this fine plantation some years ago, leaving only a fragment, but quite enough to show what I have described. The fault of the Corsican as a shelter tree is that it is a sparse brancher, but that can be got over by thick planting. The Corsican's hardiness is beyond all doubt. In the exceptionally severe winter of 1894-95, when, with us, the thermometer remained at zero or near it for weeks, and native trees like the Holly and Yew were much injured, the three species that did not show the least sign of injury were the Corsican and Scotch Firs and the Deodar. I am somewhat alone, I believe, in championing the latter, but I know it so well in many parts of England and Scotland on high-lying exposed situations and in dry soils that I am sure of it. If I wished to plant a shelter belt that would not take up much room and would be high and dense—a thorough barrier to gales I would plant Corsican, Scotch, and Deodar, putting the first on the cold side, Scotch in the middle, and the Deodar in front. In a few years these would produce a shelter from cold wind and gales that a stone wall of the same height could not surpass. Comparatively speaking, these are all storm-fast trees, and do not go down before the wind like the Spruces.

I am aware that there are other species as

hardy as those named, but I am here speaking of hardiness in conjunction with trees worth growing for timber or purposes of shelter. Such species as the dwarf mountain Pine, Siberian Pine, *Abies alba* and *nigra* (white and black Spruce) I regard as worthless for either of the above purposes. J. SIMPSON.

FRUITS FOR THE GARDEN.

Those who have still to give orders to nurserymen for trees may like the names of the best varieties. Other good kinds may be added that are known to succeed in the neighbourhood. It is better to plant several trees of the best kinds than to plant inferior ones for the sake of variety.

Apples, Dessert. Beauty of Bath, Irish Peach, Devonshire Quarrenden, Worcester Pearmain, Blenheim Orange, Margil, King of Pippins, Ribston Pippin, Cox's Orange Pippin, Cockle Pippin, Mabbot's Pearmain, Adam's Pearmain, Mannington's Pearmain, Scarlet Nonpareil, Claygate Pearmain, Golden Russet, Lord Burleigh, D'Arcy Spice, Court pendu Plat, Wealthy, and Wyken Pippin.

Kitchen Apples. Keswick Codlin, Lord Suffield, Lord Grosvenor, Ecklinville, Stirling Castle, Golden Spire, New Hawthornden, Golden Noble, Lord Derby, Tower of Glamis, Warner's King, Bismarck, Yorkshire Beauty, More de Monage, Wellington, Lane's Prince Albert, Newton Wonder, Lady Hemiker, Bramley's Seedling, and Dutch Mignonne. The last-named and Lane's Prince Albert are the two heaviest cropping varieties I am acquainted with.

Pears. Doyenne d'Ete, Beurré Giffard, Souvenir du Congrès, Clapp's Favourite, Williams' Bon Chrétien, Triomphe de Vienne, Fondante d'Automne, Louise Bonne de Jersey, Thompson's, Garonne de Mello, Durondeau, Marie Louise, Pitmaston Duchess, Emile d'Heyst, Beurré Superfin, Beurré Bose, Knight's Monarch, Doyenne du Commerce, Josephine de Malines, Minc, Treyve, and Olivier des Serres.

Stewing Pears. Catillac, Gijogil, Uvedale's St. Germain, Verulam, and Grassane. The last-named is a very heavy and regular cropping variety.

Plums. Rivers' Early Prolific, New Orleans, Denniston Superb, Transparent Gage, early and late, Kirk's, Victoria, Green Gage, and Monarch. All varieties mentioned may be grown as pyramids or bushes.

Currants, Red. Ruby Castle, Red Dutch, and La Versaillaise.

Currants, White. White Dutch and White Versailles.

Currants, Black. Lee's Prolific.

Gooseberries. Yellow Sulphur, Whitesmith, Langley Beauty, Crown Bob, Whinlam's Industry, and Warrington.

Raspberries. Superlative is the finest of all. G. NORMAN.

The Gardens, Hatfield House, Herts.

Nerine undulata. During the last three months of the year the different species and varieties of *Nerine* are very pleasing, but with the advent of January few are left. Two are, however, still in flower, viz., *N. Manselli* and *N. undulata*, also known as *N. crispata*. In this last the slender flower-stem reaches a height of 15 inches to 18 inches, and the flowers, which are arranged in an open head, have the segments reduced to extremely narrow proportions, so that a cluster of bloom has a particularly light and elegant appearance, which is heightened by the wavy character of the petals, from whence the names of *undulata* and *crispata* are both derived. The colour of the flower is light pink, varying considerably in intensity. Greenhouse treatment suits the *Nerines* well, the original species being all natives of South Africa, but there are now in cultivation a great many garden hybrids.

OUR BOTANIC GARDENS. I.

ROYAL GARDENS, KEW.

IT is our intention to illustrate the botanic gardens in the British dominions, and no one will quarrel with us for selecting as the first of the series the Royal Gardens at Kew. This is a splendid scientific establishment and a beautiful garden, which are not always synonymous terms. Not many years ago everyone with a grain of artistic feeling entered a botanic garden with apprehension. One was always prepared for a rude shock, and the lessons that were supposed to guide one in learning something of the flora of our own and other lands remained unheeded. Why? Because the plants were set out in ugly ways, stuck in beds regimental fashion, and behind labels big enough to hide leaf and flower—a collection of species and varieties arranged in a style to make scientific study as palatable as teaching history with a table of dates.

An awakening has disturbed the old order of things. There is much work to accomplish before all our botanic gardens can be called beautiful, but the healthful change in arranging the flowers and trees proceeds steadily, until in the near future a botanic garden will be a place to visit with a knowledge that the plants there collected together are shown in ways to display as far as possible their natural beauty. It loses none of its usefulness because artistic planting has been thought of. A Rose is a Rose still when garlanding a bush or flinging its trails of blossom over pillar and wall, but the gardeners of old thought otherwise, and crowded every species of a family into one place, with strange results. Tall and short, stont and lean were shoulder to shoulder in that unhappy medley of species to represent certain orders. Kew, with its splendid scientific past, has become

A GREAT TEACHER.

not merely to the seeker after technical knowledge, but to the man in the street, who cares

little concerning botanical lore. He becomes, however, insensibly interested in the world of flowers, their infinite variety and degrees of beauty, when shrub and plant are disposed in big groups to play their part in garden adornment. No longer are the plants set out in a living herbarium, but spread in pleasure ground and woodland, on turf and by lake-

issue of THE GARDEN to show how much has been accomplished, and to express a hope, too, that the work now proceeding will not be checked or cramped by narrow views of what such a place should be—a garden to roam in and learn from the flowers spread over the grounds that in a smaller acreage maybe it is possible to obtain good effects, even when the

IN THE LILY HOUSE.

side, in rock garden and in dell, and each year brings with it some improvement in artistic planting. Mistakes are committed, and a lingering love exists for lines of liver-coloured beds, but no gardener is perfect, nor can one hope for perfection when painting the earth with the colours of a thousand flowers. We have illustrated a few phases of Kew in the present

smoke clouds of a great city hover near. THE PLEASURE GROUNDS.

are filled with flowers through spring, summer, and autumn; and even in winter, when the earth is not frost bound, Cyclamens, the early Snowdrops, Winter Aconites, and other harbingers of brighter skies open shyly in the weak sunshine. Upon a winter day we have seen many shrubs in beauty: the golden-flowered Wych Hazel (*Hamamelis arborea*), *Lonicera Standishi*, scenting the cold air, *Chimonanthus* or Winter Sweet, and Heath. But colour, too, comes from the Sea Buckthorn (*Hippophae rhamnoides*) by the lake, and from Siberian Dogwood and Scarlet and Golden Willow. Many good gardeners have told the writer that not a few of their best effects have been suggested by the grouping of families of shrubs and plants at Kew, and in May Tulip time, when the spring flowers have flown for the most part, and there comes a lull in the garden, the beds on the rich sweeps of grass are a blaze of glory. We have never seen richer colour; it seems to pour from the big goblets of Gesner's Tulip its varieties and species almost as gorgeous in their shades of vermilion and scarlet. Until a flower is grouped its usefulness for garden decoration remains unrevealed. A Gesner's Tulip alone is sumptuous; but in a well-planned yet simple group the flower becomes of intense brilliancy, suggesting that in all places where rich pictures are desired this late spring bulb should receive its proper place. We write of the May Tulips in particular, for we think Kew is the first botanic garden to show how much has been lost in the past by not using liberally bulbs almost unknown to many good gardeners that have flowered modestly in the cottage plot for generations. The same may be written of a host of other good things, rare except at Kew, where, of course, the Director has oppor-

HYBRID WATER LILY GROUPS ON THE LAKE.

tinuities of making handsome and artistic effects, and has happily neither forsaken nor forgotten true gardening for a dry as dust herbarium.

BOTANICAL KNOWLEDGE AND GOOD GARDENING.

should go hand in hand. This meeting of two phases of flower life is seen here, and such a noble garden has an important influence upon horticulture in this country. How great has been the change from the former ugly ways of planting, may be seen in the early spring months, when the Royal Gardens are in their sweetest dress. The grass swards are filled with flowers happy under such conditions, Star Narcissi, double Meadow Saxifrage, Crocuses, Lady's Smock, Snowdrops, the fragrant Tulipa suaveolens, Poet's Narcissi, and hosts of other precious flowers of the early year. The whole garden is perfumed and coloured with these wavy colonies and sweeps of blossom. Near to the principal entrance from Kew Green the grass is full of bulbs which have now become almost naturalised,

land. But this garden is an object lesson of great value, showing that even in a low-lying river-side woodland the Bamboos are not merely comfortable but make tremendous growths. Those who visit Kew to gain information concerning things which at present are a closed volume, and wish to know how well Bamboos thrive, should spend a few hours here, where the plants have now become thoroughly established, and are fresh-looking in their green colouring throughout winter. Of course shelter is necessary, and this is provided by the surrounding woodland, the garden being set, so to speak, amidst trees, and approached in one way from the delightful dell of Rhododendrons, where many rare hybrids and Himalayan species have grown into vigorous bushes. Readers of THE GARDEN, however, have been well informed as to the species and varieties of Bamboo that succeed at Kew, and the method adopted for forming the present garden. There is no haphazard system of culture, but everything is assisted to promote its full vigour and develop its natural beauty of form, leaf,

numerous plant houses new introductions are flowered and new hybrids and varieties raised. These will be recorded in our pages week by week, and it must not be forgotten that it is a place in which flowers are hybridised to create fresh races. The Streptocarpus of our gardens practically had their birth here, and visitors to the Hybrid Conference in the Royal Horticultural Gardens last year will remember the splendid group of Kalanchoe flammea grown at Kew. This is, without question, the most important new plant of last year.

Thus we commence this present series with the greatest garden of its kind in the world. An immense work is quietly performed by those responsible for its management, in giving advice to horticulturists at home and abroad, and in maintaining a botanical influence that is felt not only in Britain, but in our colonies and countries of other nations. Of that great work we have no intention of writing about now. We regard the gardens rather from another standpoint, that of their importance in teaching that botanical science need not disfigure the woodland or pleasure ground. The Arboretum is not merely a collection of trees and shrubs, labelled and classified into their respective families without a thought of their natural growth. Fir, Spruce and Tamarisk, Oak and Beech, and every other tree and shrub group are represented by all the species and varieties it is possible to procure, and this may be written of every plant family, whether it be the glorious hybrid Nymphaeas basking in the summer sun on the lake surface, or tender exotic sheltered under glass.

We are happy in the belief that the director and his assistants realise the great teaching importance of the gardens under their charge, from whence are sent men to the four quarters of the globe to work out the knowledge of the gardening and botanical science acquired during their apprenticeship. Kew is a beautiful botanic garden; it was not always so, but the gardening spirit has made itself manifest and will reveal itself more strongly as the years roll on.

NEW GARDEN PLANTS, 1898.

ACCORDING later than usual, the Supplement of the *Kew Bulletin*, containing a list, briefly descriptive, of all the plants newly introduced into gardens in 1898, and described in botanical and horticultural publications, English and foreign, in that year, will be found useful as a permanent record for future reference. A similar list has been issued annually since 1887. It comprises not only plants brought into cultivation for the first time, but the most noteworthy of those which have been re-introduced after being lost to cultivation. Species, varieties, and hybrids, with botanical names, are included. Some idea of the character of the list will be obtained from the following example of a description taken from the list for 1898: "*Passiflora In-Thurnii*, Masters (*Gardens Chron.*, xxiii., 305, fig. 114), Passifloraceae, Stove. A new species, near to *P. glandulosa*. Leaves broadly oblong, acute, leathery, glabrous above, setulose below. Flowers erect, 4 inches wide, with oblong glandular sepals coloured bright scarlet; petals smaller, rose coloured or almost white. Mr. In-Thurn calls it 'the red and white Passion-flower.' Guiana." This last list contains over 300 descriptions, but in some years over 500 have been recorded. The lists are sold at the gardens, price 4d. W. W.

Varieties of Impatiens Sultani

The flowers of the normal form of this Balsam are bright and pretty, while two varieties are very distinct, and, though not so free, are still decidedly attractive. One of these, *carminica*, has blossoms of a bright carmine-red shade, while in *salmonea* they are salmon. Like several others of their class, these Balsams are easily grown.

FORSYTHIA SUSPENS A AND CARPET OF SCILLA.

as also in the woodland or arboretum. Poet's Narcissi in thousands gleam in the openings between shrub and tree, companions to the Bluebell, which carpet the ground in rich profusion. As the illustrations depict, happy ways of using flowers are considered; and this beautiful gardening is not of one season alone, but in summer and autumn pictures of interest and splendour are unfolded. It may be of a hundred Tiger Lilies massed beneath a group of Chili Pine, or the fragrant Mezerion with a carpeting of Butcher's Broom. Kew is a botanic and experimental garden too, and plants one would not suppose sufficiently hardy or vigorous for a climate near the metropolis of London thrive unharmed by a murky atmosphere, unless saturated with visitations of dense fog. One of the most interesting additions of recent years is

THE BAMBOO GARDEN.

This has been the means, in no small degree, of popularising a graceful family, hitherto regarded as too tender, save *Arundinaria Metake*, for our

or flower. We have never visited this garden without leaving it wiser and better informed than when we entered it, gaining fresh ideas of the way of grouping certain shrubs or flowers, and learning something of their requirements. It is to assist our readers that we shall in the future give notes of everything at Kew likely to interest and instruct. Of course there are many failures, but if a plant expires or feebly struggles for existence in one spot it is tried in another, until its requirements are so supplied as to ensure success.

Last year an important addition was made to the gardens by Her Majesty, who sanctioned throwing into the grounds the Queen's Cottage and surrounding woodland, a paradise of birds and wild flowers. This, we believe, will be preserved in its natural wildness, and visitors in Bluebell time will enjoy a walk of the azure flowers, a sea of colour, hiding the sparse grass beneath the trees with a mantle of scented blossom. But it is difficult to write about Kew without encroaching upon space that can ill be spared in this issue. In the grounds and the

FRUIT GARDEN.

POT CULTURE OF PLUMS.

THE culture of Plums in pots has not advanced so rapidly as in the case of Peaches and Nectarines. Various explanations might be given of this fact, but it still remains the same. My own impression a few years ago was that Plums were not so amenable to pot culture as other stone fruits, but I have found from practical experiments that quite the opposite is the case. Some varieties fruit more abundantly in pots than when planted out in either the orchard house or the open air.

VALUE OF THE TRANSPARENT GAGE.

The varieties of the Transparent Gage (which I consider the finest of dessert Plums) are instances of this. These Plums are very strong growers when planted out, but when restricted at the roots by pot culture they are quite manageable. In our collection of several kinds, the Transparent Gages are the most prolific of any, a tree rarely failing to carry a good crop. This is far from being the case where the trees are planted out, so far as my experience has enabled me to form an opinion. These instances could be multiplied, but it is hardly necessary save to state that it applies to all strong-growing kinds as well as those that are supposed to crop badly.

Not only is it advantageous from the cropping point of view, but it applies also, and in an equal degree, to the quality of the fruit, except, perhaps, in the more highly favoured situations and soils. I find the flavour of fruits gathered from pots more fully developed than those from the open air. This is not peculiar to any one variety, but is applicable to all. Take, for instance, the Gages already alluded to, pot-grown examples of which are extremely delicious; so, also, are such as Coe's Golden Drop, Oullin's Golden, Golden Esperen, and Iekworth Imperatrice. There is scarcely any loss; birds, wasps, woodlice, and earwigs rarely destroy fruits upon pot trees. The two last-mentioned smaller enemies are, nevertheless, very destructive to wall fruits. There is no risk of injury to the crop by heavy rains in the autumn, which will often cause splitting or cracking, nor are the fruits in any way disfigured. Those grown in pots under glass retain their bloom to perfection; in fact, it is more perfectly developed, whilst the colour is intensified in nearly every instance, the peculiar freckles, spots, and other well-defined markings being thus brought out to perfection also.

FORCING PLUMS.

Some kinds are well adapted for this, and success is as certain as in the case of Nectarines under exactly the same treatment. Plums in pots may be had ripe without any difficulty by

the end of May or the first week in June, and thence onwards to nearly the end of October a supply may be maintained. For forcing I have grown, and am well satisfied with, Early Transparent Gage, Jefferson, and Reine Claude de Comte Althaus. These have fruited well in June and July, each variety when ripe being quite distinct from one another. The stone of a pot-grown fruit of the Plum is not so large, comparatively, as from trees growing in the open, but it puts on no less flesh for all that, in some cases even more. From the standpoint of beauty, Plums in pots have much to recommend them: there is first the flowering season; and, secondly, the fruiting stage. In flower the pot Plums make a beautiful display in the

They should have been grown one year in pots previously, so as to secure a good proportion of fibrous roots.

TREATMENT OF TREES WHEN FIRST RECEIVED.

When such trees are purchased, repot them without delay, reducing the balls in every case, more or less, on no account potting them on into larger pots without any reduction at all—this is another mistake, not infrequently made in pot-fruit culture. In nearly every case these newly-acquired plants or trees will go back into the same size of pot again. Pots of 9 inches or 10 inches diameter are quite large enough for the first few years. Firm potting is essential, and it should be done equally as well as if potting a greenhouse Erica or a Cape or New Holland plant, than which no plants need more careful handling. The best soil is a calcareous loam, to which little need be added—a small proportion of well-decomposed hot-bed manure to encourage fresh root action—the same of lime rubble or crushed bones (bone meal is almost too fine) to aid in the proper development of the stones (when the crop is swelling freely, then more manure can be applied, rather than in the soil at the time of potting). After potting give a few good waterings and let the trees stand in an open position, covering up the pots as a protection against frost. Here the trees can remain until the first flowers are expanded. Then it is desirable to bring them under glass for greater safety rather than run any risk from frost which, to our out-of-doors Plums, is often disastrous. For these, a house that is provided with abundant ventilation is most desirable. J. H. HOSKIN.

*Gunnerybury House Gardens,
Acton, Middlesex.*

OLD HARDY POPLAR AND BHOTAN PINE NEAR THE PALM HOUSE.

spring, but I consider the autumnal effect is far more beautiful when the trees are well laden with fruit, whether they be the varied tints of gold and orange, deep blue and purple, or reds of various shades. If no forcing is attempted, then no artificial warmth is at all necessary, hence no cost of fuel need be entertained.

In making a start to grow Plums in pots it should be borne in mind that light is essential. One cannot expect great success if the trees be grown under the shade of other things. This is where many have stumbled when first attempting pot-fruit-tree culture. Young trees are the best to start with, *i.e.*, those from three to four years old from the time of working.

flavour compared to others that are of high quality?

During the last thirty-five years I have had an opportunity of noting the behaviour of Pears in many gardens placed in various parts of the country, as well as in varied soils and situations. I could name several kinds that I have never known to be flavourless, while others are always poor. Some kinds need high culture to obtain their best qualities; and this applies to many other fruits, such as Muscat Grapes and British Queen Strawberry. No hardy fruit repays for close attention to their needs more than Pears, and there is no need to grow many kinds that are known not to keep. In most cases two trees are sufficient; and in some instances I should recommend cordons.

The following kind I can recommend, having

PEARS FOR FLAVOUR.

No doubt many will agree with me that Pears are the most delicious in flavour of all hardy fruits, and good fruits for dessert may be obtained over a long season, some growers having material from July till April. This may be so in exceptional seasons or localities, or if the grower is content to have Pears without regard to quality; but I fail to see the wisdom of growing kinds (whatever the position or locality may be) that are useless except for cooking. This being so, then why grow kinds that are known to possess no

grown them in various soils and situations with the best results. Many others could be added, but these are some of the finest, all points considered, for flavour.

Jurgonelle must head the list. The fruit is very fine here, gathered from a south wall on the abbey, the roots running under the turf and gravel drive. The trees are more than 100 years old. This is generally of finer flavour in the north than south of England.

Bon Chretien (Williams's) every one knows to be good. It is of better flavour from trees in the open than from those growing on walls.

Fantaisie d'Automne is excellent. It is always of good flavour, and must be closely netted or the birds will destroy the fruit.

Comte de Lutray, although not large, is first-rate. I have eaten deliciously-flavoured fruit from trees in the Royal Horticultural Garden at Chiswick, as well as in Purbeck Isle.

Mme. Tregou and *Bonne Supperin* are fine in their season. When residing in North Hants I used to have noble fruits for size and flavour from bush trees.

Louise Bonne of Jersey can be depended on, although the fruit in our garden is of higher flavour from trees in the open than those from a wall, although not to be compared to wall fruit for appearance.

Mme. Louise is so well known that it needs no praise; while

Suckle should be grown by every one for flavour. Although small, I never have known it of poor flavour.

Pomme du Comte is a splendid Pear, and is being more extensively planted.

Globe Maroon, in a general way, is first rate, especially when the fruit is russety. In Hampshire it was very good from an old tree, and was in season for two months.

Josephine de Malines must be mentioned. I saw it in fine condition at Sherborne Castle early in December. The fruit is of high flavour from a bush tree.

Naucelle Futee is a good late Pear, which succeeds well at Sherborne Castle.

Winter Xalis I consider the best of all Pears. It does well with me under high culture.

Estee Bonne, and *Beyrouth d'Espagne* are good in some soils; the latter is of fine flavour here on a bush.

Officer des Sciences is reliable, but of poor growth. Culture and site have much to do with flavour as also the stock the trees are worked upon.

J. Crook.

Chard, Somerset.

APPLE COCKLE PIPPIN.

This is an old and valuable dessert Apple of medium size and rich aromatic flavour. Although not so handsome as some Apples, few late-keeping kinds are of better flavour.

I remember some fine trees in an orchard at Heddon Park twenty-five to thirty years ago, and these produce fine fruit. The tree is not of large growth, but bears abundantly. When at Sherborne Castle, early in December, I saw in the fruit room a quantity of this kind. J.

RED CURRANT LA VERSAILLAISE.

This should be more known, as it is a long-bunched, late-keeping kind. I grew it some two years ago, and the only drawback to it is that the bushes are of stiff growth, and when heavily fruited large branches are apt to break off, which, in some instances, renders the bushes practically useless. This can be remedied by pinching or stopping them when young so as to form a base. It would pay to train this Currant on walls, boards, &c., to obtain a late supply.

Can anyone tell me the difference between this and Fay's Prolific, which I saw once in a garden near Minehead, but had not La Versaillaise to compare it with? J.

TREES AND SHRUBS.

RHODODENDRONS IN LARGE GROUPS.

THE value of a simple grouping of one good flowering plant or shrub can hardly be too highly rated. It is a lesson of such importance in good gardening, that we desire to take every opportunity of referring to it. A group of Rhododendrons, towering masses of bloom, some 18 feet high, shows how a noble mass of one thing alone goes to the composing of a satisfying garden picture. It also shows the beneficial service of shrubs of large growth in giving interest to the hard line of a rectangular pool by breaking over it, and boldly insisting on the display of its own unrestrained growth.

For this class of treatment no kinds are better than well-chosen seedlings of *R. ponticum*. But there are also two good old garden hybrids, namely *album grandiflorum* and *album elegans*, that have tall, vigorous growth and abundance of bloom, qualities that befitted them for large and pictorially-treated groups, while their colour suits admirably with the seedlings of *ponticum*. But as these vary a good deal in tint, it is well to pick them out in the nursery at blooming time, when it is easy, by taking two blooms in the hand, to go round and assort plants, either for one or two groups of the warmer and cooler shades respectively. The effect is much better, even in a large planting, if one only of these shades of purple is used throughout with the tall growing whites.

Such a grouping would have a fine effect in a rather large space of moist, peaty ground, and it would look all the better for some well-grown groups of Silver Birch.

MISTLETOE.

There is something strangely attractive about this curious plant, something mysterious that rouses the imagination. It is attractive, and yet at the same time slightly repellent, for it has somewhat of a vampire nature, in that it sucks out and lives upon the life blood of some honest tree. Moreover, it is both ugly and pleasant to see, for it hangs in rather ungainly bunches and masses, and yet is beautiful in detail. In fact it is so simply constructed that it gives one the impression of being low in the scale of vegetable creation. It is built almost as simply as a seaweed, but there is a strange and rare kind of beauty in the individual twigs, and especially in the relation of colour between the golden-green leaf and the pearl-white berry.

The trees it most frequents are Lime, Apple, Poplar, Thorn, and Mountain Ash. The seed can be sown by fixing the berry either in an artificial slit, or a crack in the bark of any likely tree, preferably on the underside of a branch. Such sowings are often ineffectual because the seed is used before it is ripe. It is no use taking it from boughs as sold about Christmas time, for the seed is not ripe till quite two months later.

Mistletoe abounds in some English west-county Apple orchards, but is in still greater profusion in those of Brittany.

PERNETTYA MUCRONATA.

Why is it that this beautiful, useful, and perfectly hardy plant is, comparatively speaking, so little known? Although its period of greatest charm is from early October to early spring, when, if the winters prove like those of 1897 and 1898, the lovely berries, which the birds rarely touch, will be still in good condition, it is beautiful all the year round, distinct in foliage and flower, of most easy culture, apparently indifferent as to soil, and although requiring full light to berry really well, it will even thrive in half shade. It is a plant that ought to be in every garden, and yet in how many gardens does one see it? Admired by all, one's friends invariably ask for the name, the keenest

and most energetic going so far as to write it down; but their energy and interest seem to cease. Figured some fifteen years or more ago in THE GARDEN, and frequently shown in berry at the Royal Horticultural Society's shows, it is passing strange that, as I say, it is so little grown.

After all, the *Pernettya* is not alone in being admired and neglected; it would be easy but useless to make a long list of beautiful hardy plants which are always admired, but never grown by their admirers. Lovers of the garden and gardening, who would spare no trouble to secure some plant which they have seen doing well elsewhere, can at times hardly realise that their friends can really care for the plants which they admire year after year, when they seldom get beyond asking the name, and seem to never get so far as to grow the plant themselves. Candidly, I sometimes think they expect me to take the plants round in a barrow and plant them in their gardens for them. In my early gardening days I was weak enough when a friend asked for a plant to make a note and send it at the right time, but years ago a very well-known gardener, whom I have to thank not only for many choice plants now thriving here but for the precept and example which have greatly helped me in my gardening efforts, gave me a most valuable hint, one which has saved me endless unnecessary work.

Apocryphal of this careless butterfly class of gardeners who would like to have a pretty garden, but will not take the slightest trouble to make one, I will pass on the hint in the hope that it may be of use to others as it has been to me. The matter came about in this way: I was walking round a friend's beautiful garden, and the owner, a lady, was making notes of any plants I wanted, when she informed me that she always divided her gardening friends into two classes; to the second class she said: "Oh! you like that plant, then I shall be most pleased to send you a piece if you will let me have a postcard in October" (or whatever was the right month), but to the others she sent the plants without reminder. Naturally, I was pleased to find myself in the *first class*, but was informed that I had obtained my promotion solely by *never failing to send the necessary postcard*. Before that day I was foolish enough to think that when one's gushing gardening friends were profuse with thanks about some promised plant they were really interested, but when they received it, the letter of acknowledgment showed clearly that they had forgotten all about it.

But now that I adopt the above classification I know better, for not once in ten times do I get the reminder. May I add that the garden was Muirstead, and my friend Miss Jekyll.

A. KINGSMILL.

Harlow Wood, Middlesex.

Brownea Crawfordii. A large specimen of this *Brownea* in the Palm house at Kew is just now bearing a number of its pendant clusters of bright-coloured blossoms, which, seen in the sombre light of a midwinter day, appear particularly rich and telling. It is quite a tree of 20 feet in height, or thereabouts, clothed with long pinnate leaves. At a little distance the flower clusters suggest trusses of Rhododendrons, except that they are drooping, but closer inspection reveals the fact that the individual blooms are quite different, and closely packed. The colour is a kind of rosy or salmon scarlet. The *Brownias* belong to the natural order Leguminosae, but to the casual observer they appear to have no points in common with the generally accepted types of that order. There are several species, nearly all of which are among the finest of tropical flowering trees. *B. Crawfordii* is a hybrid raised in the gardens of the late W. H. Crawford, Lakelands, Cork (noted as being the first plant in the British Isles to flower *Magnolia Campbellii*, the parents being *B. grandiceps* and *B. macrophylla*). These gorgeous plants require a very large structure, such as the Palm house at Kew, hence suitable accommodation can only be given in a few gardens. One species, however, *B. coccinea*, can be flowered.

GARDEN THOUGHTS.

FLOWERS IN GRASS.

FROM very early days it has been the practice to grow the commoner kinds of double and single Narcissus in meadows and orchards; and within a recent period most of the rarer kinds have been found to prefer grass-land to cultivated ground, and with the best possible effect; but so far as my observation has gone, with the exception of Snowdrops and Crocuses, the Narcissus stands nearly alone. This seems to me a mistake. There are many other flowers of equal beauty and perfectly adapted to similar localities. I might instance the blue, pink, and white Spanish Harebells, *Scilla italica*, Snowflakes, and, perhaps, Columbines of different colours; and, when the grass is not very rank, I have found *Scilla precox* and *S. bifolia*, *Chionodoxa*, Muscari, and hardy Cyclamen to do well. Perhaps, above all, the chequered and white Fritillaries give most satisfaction. Many of the Alliums are very beautiful, but too dangerous in their increase to be lightly introduced; Colchicums are very suitable, where cattle are not likely to be poisoned by them. I have found both Fritillaries and Cyclamens to increase in the grass, but it has been my practice to keep a seed-bed of each annually in the kitchen garden, and to plant out the second or third year. If it be a fact, that to gather a Fritillary flower is to kill the plant, the seed-bed will allow you to gather some of the flowers, and yet keep up the stock. Both kinds are equally graceful, but, for effect in the meadow, the white should predominate.

I have always been anxious to naturalise the Sternbergias, especially *S. angustifolia*; both flower very fully in the garden, but in the grass a solitary bloom has been my only reward; they require sun at the root. I have also tried one English Tulip (*T. sylvestris*), which flowers freely in North Wales (one of its natural habitats), but I have had no success; it thrives, but does not flower. Even in the garden it does not flower very fully, not to be compared with its very near relative, *Tulipa fragrans*; and from its stoloniferous habit it becomes a troublesome nuisance, springing up where it is not wanted, in the midst of other plants.

If any of your readers are inclined to enhance the unimproved spots in their grounds, it is not too late to procure the material for the coming season. Among the autumn Crocuses I have found species and multiflorus the most satisfactory in grass, and least attacked by mice and voles. As regards *C. multiflorus*, the grass is particularly useful in supporting the long, naked stalks, which in the border are beaten to the earth by the first heavy shower.

T. H. ARCHER-HEND.

Cumulisshutere House, South Devon.

CRINUM CAPENSE SEEDS.

I HAVE recently had a curious experience with seeds of *Crinum capense*. A few were put aside in a bag after gathering. On opening the bag a few days since, I found they had all germinated and produced a small bulb with plumule, ready to pot. The experience is not, however, new; the same thing has occurred before, but I never met with any reference to a similar incident. The seeds of the Xerines behave in the same manner. What a contrast between these seeds and others which no skill can induce to germinate, such as those of the new *Polygonum bald-chameneum*.

Upton

Wm. THOMPSON.

RIVIERA GARDENING.

GREAT pleasures and great pains are so nearly akin, that northern gardeners who sigh for sunny lands and sheltered valleys will feel somewhat consoled for their own distresses

when some of the difficulties of a southern garden are placed before them.

Occupied as I am just now in wrestling with "Nature" on a sunny hillside not far from Nice, I am constantly reminded of old Horace's dictum "*Natura facit capellas, tamen usque reuerit*." Yes, indeed, Nature does reassert herself with a vengeance in these climates, even though you may expel her at the fork's end, and by dint of much water and much manure. The *bichou*, the two-pronged fork is still the weapon the gardener uses, and with a mighty effort he delves down to more than a yard in depth before he will allow a plant to be put in the ground, for unless the plant's roots can have a deep run, the summer heat and drought will wither up both root and top, so that on your return in autumn you will but find a tangle of weed overtopping the dead remains of the plants.

All one's loved northern plants must have complete shelter from the fierce heat and sun of summer if they are to succeed; and, as by exceptional fortune there is a moist and deeply shaded valley in my ground where such plants can live, I am occupied in making an English garden, where at least no spring frosts or biting winds can harm them, so that in a few seasons I trust that a wealth of spring blossom may be realised, set off and framed by southern surroundings.

The difficulty of getting a French gardener to plant this, may be realised only when one finds that, to his idea, everything must be planted in rows and in a trench, so that left to himself your garden is a gridiron, very convenient for watering and retaining moisture no doubt. Last spring I planted carefully, and as I thought artistically, some hundreds of *Cyclamen persicum* in my wood, where there is abundance of good leaf-mould and shelter, and I left, picturing to myself the charming effect the marbled leaves and brilliant flowers would have coming up through ivy trails under the trees. What did I find on my return, but long rows of my poor *Cyclamen* which had been dug up to edge the paths in formal lines, and next, a row of Tulips, and then Daffodils behind, all neatly and beautifully edged with an *Echeveria*-like *Sedum*.

A long grass terrace was planned with tree Peonies at the edge and frises on the bank. I found the grass carefully sown at the sides, and the frises edging a stiff straight walk in the middle; so no further need is there of stating how the nature of that man needs expelling. And yet how infinitely delightful that man is, how dextrously he wields his tools, and handles his plants as if he loved them. Yet to him it was not possible to do otherwise; it was an insult to his best feelings.

The rough grassy bottom of this valley is carpeted with myriads of starry Anemones, lilac, white and sometimes crimson, wherever a little natural hybridisation has taken place between the *Anemone stellata* and the golden-eyed scarlet "Soleil" Anemone, which also grows there in lesser quantity, and which is so much more lovely than *A. coronaria* can be at any time.

Narcissus *Tazetta*, both the early yellow and the late white orange-eyed, spear up among the bushes, relics of the good old days when they were wild on every terrace, though now it is only in some nook like this that they survive. Wishing to beautify a bare spot where brambles have been dug up and burnt, I send out some quantity of *Anemone fulgens* to plant there. Unluckily, I said "sow some grass seed over them." In consequence of my rash order the grass was duly sown, but the *Anemones* were planted in a rectangular pattern round the

sacred square of grass—thus destroying all the beauty I had aimed at.

There are none the less great pleasures. One for instance is a pergola that I planted last May with *Taesonias*, *Heliotropes*, *Bignonias* of sorts, climbing yellow *Senecios*, Ivy *Geraniums* and *Roses*, purple *Kennedias* and yellow *Cassia tomentosa*, which in winter takes the place of *C. corymbosa*. To describe the luxuriance of growth and the abundance of flowers in November and December is hardly possible without laying oneself out to the charge of exaggeration, and this feast of colour and scent will go on throughout the winter, unless some exceptionally cold night or storm from the mountain nips the more tender plants for a time. As there has never been any frost or snow to cut even a *Heliotrope* here since 1895, it is only too likely that 1900 may signal its arrival by an icy blast; meanwhile, it is well thankfully to enjoy the sunshine, while looking forward to the spring display of hardy plants which enjoy a little snap of winter cold.

E. H. WOODALL.

RECENT PLANT PORTRAITS.

The first portfolio of the fourth series of Messrs. Cogniaux and Goossen's "Dictionnaire Iconographique des Orchidées" contains admirably coloured portraits of the following thirteen Orchids, with descriptions by the editor:

Angulosa Chavensis. The well-known yellow Cradle Orchid.

Cattleya Allana inversa. A beautiful variety, with light rose-coloured upper petals and deep carmine lip.

Cattleya Rex. A most beautiful variety, with pure white upper petals and delicately-pencilled tube and lip.

Cochlioda coccinea. A pretty, small rose-coloured flower.

Dendrobium Victoria Regina. A pretty flower, coloured violet and white.

Epidendrum atropurpureum var. longiloba. A handsome variety with dark brown upper petals, with greenish backs and pure white lip, with deep rose blotch at throat.

Epidendrum goldianum. A curious globular bunch of small golden-yellow flowers.

Grammatophyllum Rumphianum.—A medium-sized flower, with green petals, heavily blotched with brown and a whitish centre, curious but not beautiful.

Lelia avathina. A beautiful yellow flower with whitish centre and delicately-pencilled lip.

Macillaria striata. A curious flower with brown and yellow colouring, and yellow tips to the two upper petals.

Mormodes Oceana. A handsome deep-red flower, the four upper petals curiously spotted.

Mormodes buccinator. A curious and not ornamental brown flower, with lighter shaded under-petal.

Mormodes buccinator var. citrinum. A much prettier flower, of a deep yellow colour, with whitish centre and curious incurved petals.

The first monthly part of the fifteenth volume of *Limbria* contains handsome life-size portraits of the four following Orchids:

Compurallia speciosa. A beautiful pendulous raceme of soft deep rose-coloured flowers like a small *Phalenopsis*.

Cypripedium Argus var. nigricans. A rather dull slipper plant, with greenish-white sepals, heavily blotched with blackish-brown.

Oboloblossum crispum var. Rosette. A pretty variety, with all the flowers in a bunch on top of stem instead of in a pendulous raceme, as is usual in this family. The ground colour of the flowers is pure white, blotched with rose-brown.

Arachnanthe Calceata. A very handsome large flower, with deep brown petals, regularly and evenly veined with white, and a prominent yellow lip also veined and lined with rose. This was long known as a *Vanda*, but has now been separated from them and renamed by the botanical authorities as above.

W. E. GIMBERTOS.

AN ARTIST'S NOTE-BOOK.

GIANT VIOLETS.

(With Illustrations by H. G. Moon.)

ONE hears that the Violet is being ruined, that we are robbing it of its "modest" character—whatever that may mean—that the scent is disappearing, and that instead of a Violet we are producing a monstrosity which partakes largely of the character of the Pansy.

in which sample blooms have been sent have retained the perfume for months; and when the boxes of flowers have been taken to the local post office, although the boxes are tight fitting and closely wrapped in brown paper, the employes have immediately detected the nature of the contents.

With regard to the size of the Violet, there is no reason why this flower should be singled out from all others and no advance allowed in size. In nearly everything else increased size means increased usefulness, provided that other qualities are not neglected, and, in spite of the few objections, we are satisfied that the vast majority of those who love flowers are grateful beyond measure for "Giant" Violets.

We may say that increased breadth of petal and length and strength of stem have added immensely to the decorative value of Violets.

VARIETIES.

La France is the latest addition, and is an improvement, in many respects, on Princess of Wales. It has only recently been possible to arrive at this conclusion, but they have now been fairly tested. La France is more compact in growth, which is a consideration where quantities of flowers are required and the space is limited. It is also a larger flower, and of a richer and darker colour. Lastly, it is certainly more free flowering than the other.

With regard to Princess of Wales we may say that it will be a long time before it can be discarded. The long stout stems, and perfect blooms and foliage, and the vigorous constitution, have ensured for it a long-lived popularity. In passing, it is perhaps as well to point out

that there is a mongrel stock in circulation, which can give no correct idea as to the value of this variety when true.

Luxonne is a large and graceful French variety, which flowers very freely in the autumn, and seems as hardy as any. The stems are long, and the flowers are well protected by the abundant foliage.

California is still good, and is useful when

DOUBLE VIOLET MARIE LOUISE.

We may remark in passing that a flower show is not an ideal place to ascertain the perfume of anything—except, perhaps, tobacco—and certainly when Violets have been gathered the previous day, carried 200 or 300 miles, and placed by the side of Roman Hyacinths or of Apples, it is somewhat irritating to be told on the third day that "your Violets have no scent."

There is no question about this, the Giant Violets are strongly and sweetly scented. People standing on the gallery at York Chrysanthemum Show said that the perfume was most noticeable, although the Violets were on the floor of the hall. Many times we have heard the remark by those who have been standing with their backs to the exhibit and yards away: "Where are the Violets?" Envelopes

VIOLET PRINCESS OF WALES.

Violets are grown entirely in the open air. The cultivation of these Violets is by no means difficult. Propagate by cuttings, not by division. Keep the plants cool and partially shaded during the summer months, and if you must lift them, this should be done as late as possible. If you would have fine blooms, you must have strong healthy plants, and to those who prefer twenty five large blooms to fifty small ones, we say cut off the runners.

Red spider is the great enemy, but this pest is not very troublesome when the stock is healthy to commence with, and the plants have not been allowed to suffer from drought.

Westbury-on-Trym.

J. C. HOULST.

Rosomanes, but far more brilliant, and highly fragrant. We want more of this type, and also of such Roses as Viscountess Folkestone, Caroline Testout, and Mme. Abel Chatenay.

At present the Hybrid Tea group possesses too many of the Lady Mary Fitzwilliam class. We need to break away from these. Mme. Abel Chatenay and Grand Duc Luxembourg are two of the most beautiful of modern Roses. The former, with its delicious salmon pink tint and sweet fragrance; and the latter, with its distinct shades of brilliant lake and rosy red.

As the Hybrid Teas have been frequently alluded to in THE GARDEN during recent years, it will be unnecessary to dwell upon the merits of such well-known kinds as La France and its sports, Augustine Guinoisseau and Duchess of Albany, Camoens, Grace Darling, Gustave Regis, White Lady, Mme. Pernet Ducher, Gloire Lyonnaise, Kaiserin Augusta Victoria, &c., but rather direct attention to a few little-known or recent

base of petals. The buds are long and pointed. Altogether a good garden Rose.

Aurore is very free flowering, sweetly fragrant, and vigorous in growth. If severely disbudded its flowers become very large. It was finely shown in pots at the Temple Flower Show two or three years ago.

Mme. Eugène Bouillet. A very distinct variety in colour. It may be described as yellow, with a salmon and carmine shading. Probably this will make a good exhibition Rose. Its growths are stiff and strong, after the Hybrid Perpetual style.

Ferdinand Batet is another with conspicuous yellow shading. Although not large enough for exhibition, the flowers are evenly arranged, and the colour delightful. This yellow shading is characteristic of many of the newer Hybrid Teas. A really fine Rose is

German Trochu. In growth it is very vigorous, but stiff, and its flowers are produced in fine trusses. The colour is a pretty orange yellow. This variety and Gustave Regis are just the kinds to plant for bold effect. In large gardens one requires some tall beds for certain positions. If the plants are obtainable with an erect habit, so much the better. Therefore, this Rose is adapted for this purpose. Two other fine garden kinds are

Clara Watson and *Souvenir du Président Carnot*, the latter resembling a refined Souvenir de la Malmaison.

L'Innocence. It has been good under glass, but that is often very misleading as to the behaviour of a Rose outdoors. I should like to know more of this kind in the open.

HYBRID TEA ROSES FOR SHOW.

The following may be accepted as genuine additions to our show Roses. First to mention is

Mrs. W. J. Grant. One cannot speak too highly of this magnificent Rose. For beauty of petal it is unrivalled, and it is wonderfully free. I cannot say I care much for it in autumn. Its fresh colours seem to have gone.

Marquise Litta I believe will be extensively grown under glass for market. It is one of the best pot Roses, and we have evidence of its popularity as an exhibition flower by the large numbers shown last season.

THE ROSE GARDEN.

PLATE 1256.

HYBRID TEA ROSES.

(WITH A COLOURED PLATE.)

THESE are many signs that decorative Roses are becoming more popular every year. Those varieties that make effective groups and are useful to gather with long stems are preferred to the exhibitors type, with perhaps one blossom to a plant.

The Hybrid Teas provide many of the best decorative Roses. I do not say they do so exclusively, for there are among the true Tea-scented, Chinese, Bourbon, and Polyantha groups varieties equally as decorative.

The formation of this Hybrid Tea class has been the cause of much dissension among rosarians. It matters little what one may call a Rose, if it is beautiful in the garden. The hybrid illustrated is one of the best of decorative Roses. Its full beauty is seen when a hundred or more plants are massed together. I believe, however, it will be eclipsed by the more recent German variety, *Gruss an Teplitz*. This is a typical garden Rose, growing as freely and in somewhat the same style, as *Gloire des*

VIOLET LUXONNE.

HYBRID TEA ROSES.

Taking the true decorative kinds first, the following are all worthy of a place in any collection:

Antoin Riviere. The flowers of this are rosy flesh shaded with yellow, Camellia-like in form and very beautiful.

Kilbarnock. Most distinct and attractive; large, semi-double, pale pink flowers and exquisitely pointed buds, growth vigorous, quite as free as Viscountess Folkestone.

Mme. Jules Gröbe. A very fine kind. Its clear silvery rose colour is perfectly distinct from any other Rose. There is also a pretty yellow shading at the

VIOLET LA FRANCE.

Mme. Cadeau Raney has also gained notoriety, and deservedly so. Its fine globular high-centred form and rosy flesh colour, with a distinct yellow base, make it a valuable addition to our show Roses.

Tunneyson is a Rose that will be warmly welcomed by exhibitors, not so much, perhaps, for its form as for its splendid lasting qualities. It was finely shown at Manchester, and also at the Hybrid Conference at Chiswick. On both occasions the heat was tropical, but this seemed to have no effect upon the substantial flowers.

Papa Lambert should make a good exhibition flower, that is if the colour, which is rose, proves to be clear enough. In growth it much resembles *Baroness Rothschild*.

Bessie Brown is a magnificent variety. It is of pointed globular form, and appears to be of vigorous growth.

A word or two as to

STOCKS

may be acceptable. I have found the Briar the most suitable; but I am aware the Polyantha stock finds much favour, especially if budded where the plants are to remain. The hedge Briar undoubtedly yields the finest exhibition flowers, but for the garden the Briar cutting or seedling Briar are by far the best stocks for Hybrid Tea and Tea-scented Roses.

If I had a shallow soil, I should have the majority of my Roses upon the Briar cutting. Their roots are more spreading than the seedlings, but where a good depth of soil is available, then I would select the seedling Briar.

PHILOMEL.

THE PROTECTION OF TEA ROSES FROM FROST.

It will, I think, be generally conceded that our modern Roses are, as a rule, far more beautiful and far more free-flowering than most of the old-fashioned varieties still in cultivation. Indeed, the advance made during the last thirty or forty years towards perfection of form, in variety and charm of colour, and in floriferousness is little short of marvellous. There are, however, two important qualities, in which it must be confessed many of the old-fashioned Roses, when compared with those of the present day, are superior. They are, generally speaking, more sweet-scented, and are, moreover, of a harder constitution.

As regards the latter quality, with which we are for the moment more particularly concerned, there are but few of our up-to-date Roses which do not suffer to a greater or less extent whenever the winter happens to be in any way exceptionally severe. Take, for instance, the last cold winter that of 1894-95; the only Roses in my collection, with two exceptions, which passed through it altogether uninjured to the tips of their shoots, and which can therefore be regarded as perfectly hardy, were such very old favourites as the common Provence or old Cabbage, as it is disrespectfully called; its equally fragrant sister, the common Moss; that ever-blooming Scotch Rose which is much less frequently grown than it should be, *Stanwell Perpetual*; all the Austrian Briers; and that rampant and hardy Ayrshire Rose, *Bennett's Seedling* or *Thoresbyana*. Two of the pioneers of the Hybrid Perpetual race, *Jules Margottin* and *Duchess of Sutherland*, were but slightly injured. Now, the only modern Roses in my rose garden which could compare with the foregoing in hardiness, if we adopt the same severe test, and except such single-flowered varieties as some of the *Rugosas* and Hybrid Sweet Briers, were that charming Hybrid Tea, *Gustave Regis* and *Crimson Rambler*.

Among the Roses most largely grown in the present day, the Hybrid Perpetuals are undoubtedly the least tender. In this class the varieties which are more or less thorny stand, I find, hard winters the best, especially *A. K. Williams*, *Mme. Gabriel Lantet*, and *Marie Baumann*. On the other

hand, such smooth-wooded kinds as *Comtesse d'Oxford*, *Pride of Waltham*, *Reynolds-Hole*, and the like are remarkably susceptible to frost. Next in their ability to withstand keen winters come the Hybrid Teas, some few of which—for instance, *La France* and *Gustave Regis*—are quite as hardy as the hardiest of the H. P.'s. At the bottom of this scale of hardness we must unfortunately place that lovely section, the Teas and Noisettes.

These tender, or at best only half-hardy, Teas and Noisettes, are, as is well-known, among the choicest and most delicately tinted of all Roses, and are therefore well worthy of any extra care and attention they may require in order to preserve them from severe injuries during the winter months. All varieties are by no means equally tender. Of those least susceptible to cold may be mentioned *Francisca Kruger*, *Mme. Lamblard*, *Anna Olivier*, *Caroline Kuster* (*Noisette*), *Souvenir d'un Ami*, and *Souvenir de S. A. Prince*. Whereas such kinds as *Sunset*, *Perle des Jardins*, *Mme. de Watteville*, and *Niphotos* suffer most keenly during periods of severe or prolonged frost. In all

BLEAK AND EXPOSED SITUATIONS.

and particularly where the soil is cold and retentive, Tea Roses should be grown, as recommended many years ago by Mr. George Paul, in beds raised a few inches above the general level of the ground. This plan will tend to keep the beds warmer and drier than they otherwise would be. In cold districts it will also be well to thin out all the sappy shoots early in November, in order to arrest any further growth of the plants, and at the same time by admitting additional light and air to enable those that remain to become better ripened before the winter sets in.

I have tried many methods of protecting both dwarf and standard Teas, and have come to the conclusion that, after all, the simplest and the most easily applied prove in the end the best. For instance, dwarf plants need only have the surrounding soil drawn over their crowns to the height of 4 inches or 5 inches in order to preserve them from serious injury. In a severe winter the shoots rising above the covering of soil may be, and no doubt will be, greatly damaged; but when these shoots are cut away at pruning time the plants will in most cases start again into growth as vigorously as usual. Further protection, if desired, may be afforded by twisting in lightly pieces of bracken among these shoots. I have, however, invariably found that such additional protection, although doubtless of some service in moderate winters, was rather harmful than otherwise during a very mild one, and not sufficient to do any real good in any winter of exceptional severity. Many apply a mulching of manure to the beds in the autumn, but the earthing-up method is preferable, as it affords the plants more efficient protection without keeping the soil in a cold and sodden state should the winter prove wet.

STANDARD TEAS.

are the most difficult to protect. Of all the plans I have tried, the following I have found the most effectual. In the first instance, to shield the most vulnerable part of the plants from injury, a hay-band should be wound round the junction of the Rose with the stock. Then, in order to prevent rain and snow finding their way into the centre of the head, the best shoots should be gathered together and fastened as far as practicable in a conical form to the top of a stake firmly driven into the ground and passing through the head of the plant and above it. Some straw should then be combed out and the head lightly thatched with it, and the upper ends secured to the stake, adding one or two horizontal ties lower down to keep the straw in its place during high winds. It will be found helpful in carrying out this method of protection to cut out in the first instance all the soft and sappy shoots.

For climbing Roses on walls I find that fine cotton matting or tiling this, a double thickness of ordinary fish-netting, arranged loosely, but firmly secured over them, will be found in all but very exceptional cases sufficiently effectual. This plan has the further advantage of not excluding light and air from the shoots, so that they do not

become as tender as when a mat or other close material is used in a similar way. Another plan would be to place pieces of fir or bracken among the branches. While on the question of bracken I may say that this term to be of any real service should be cut early in the season, for if cut when it has turned quite brown it becomes brittle and of comparatively little value.

When several mild winters occur in succession the tendency is to undervalue protection of any kind, or, at all events, to defer affording any shelter to Tea Roses until reminded of its necessity by the sudden advent of an unusually severe frost, when no earthing-up of the dwarf plants is possible and the thatching of the heads of the standards is equally impracticable. Under such circumstances the only thing to be done is to place some bracken or dry leaves round the dwarfs and work in some bracken or light evergreens into the heads of the standards.

But the wise rosarian will not allow himself to be caught napping in this way, but will arrange some fixed date in the early winter—say the end of the first week in December—and, having a supply of bracken and straw ready, will at once proceed to carry out the foregoing or similar directions for the safety of his Teas. I mention a supply of bracken because, should the soil in the beds be saturated, some of this can be tucked round the lower part of the dwarf plants in order to keep the wet soil coming into direct contact with the shoots. None but the enthusiastic Rose grower can appreciate the feeling of comfort and relief which comes over him whenever a sharp frost sets in unexpectedly, as it did in December last, when he knows that all his delicate Roses have long since been securely protected, and that no cold wind, heavy snow, or keen frost that may follow can seriously injure them.

Berkhamsted.

EDWARD MAWLEY.

NATIONAL ROSE SOCIETY.

SUGGESTIONS FOR COMPETITIONS IN CHAMPIONSHIP CLASSES.

HAVING been a pioneer in the movement for an amendment of the National Rose Society Exhibition Schedules in 1894-1892, in which effort I was much helped by the then Editor of THE GARDEN allowing me to give my views *in extenso*, I do not think that some further suggestions which I now make on the subject of N.R.S. exhibiting will be received in bad part by the members of the Society.

The venerable Joint Secretary of the Society, the Rev. H. Honeywood D'Ombraim, was one of my toughest opponents when I carried my point in 1891, but he has been one of those who, since then, most frequently and generously acknowledged the value of the changes made on behalf of the smaller exhibitors and stated that it has given them great encouragement, thereby also obtaining recruits. In what I now suggest I hope that Mr. D'Ombraim will be my supporter, for the important reason that he is one of those who has frequently expressed his wonders and fears as to who can be the successors to the present champions among Rose exhibitors in the highest divisions.

It is in order that there should be encouragement for such competition in the future that I now write, as I fear that if the highest prizes continue to go year after year to a few—a very limited few—it is at present the result may be that when those who are now almost always champions cease to exhibit there will be no successors worthy of the name. The aspirations of many now exhibiting may by then have been so damped by long waiting that they will have ceased to be interested in Rose-showing, except in a very small way.

To remedy this, I would suggest that the system of exhibiting in championship classes and for all special prizes but those which are given to be won outright or within a limited number of competitions should be varied or altered to the extent that any winner of a championship or first prize in any class or division for two or three years in succession should by that fact be barred from showing in that particular class for the year following such success. This would give those who are keen exhibitors a chance of winning one of the champion-

ship or best prizes, and make them, having been once successful, anxious to retain what they have won. I notice little inclination at present on the part of those in Divisions B, C, and D to move up; they stick where they are, partly because they fear to compete against exhibitors who are well known to be almost invincible in the higher divisions, and partly because they win easily in the small classes. Having to a great extent given up exhibiting, except in a very moderate way, I speak more for others than for myself; but I believe that unless something be done by the Society in the way I now suggest, or in some way approximating thereto, the future promises poor exhibits in our premier Rose classes after the present champions have decided to retire, having previously frightened away any who might in time have been their equals. This would be a misfortune in a way for the Society, although my own views, frequently expressed some years ago and still unaltered, are that small exhibits of six, twelve, and eighteen distinct flowers are far preferable and lead to infinitely more interesting competitions than exhibits of twenty-four, thirty-six, forty-eight, and seventy-two flowers. In the former instances you are likely to obtain exhibits of perfect specimens, whereas in the big competitions the exhibits are frequently uneven and imperfect; taking off in boxes is very frequent, detracting greatly from the general appearance of exhibits set up by even our crack growers. Those who have tried a hand in setting up thirty-six or forty-eight Roses know the difficulty in maintaining excellence after the first twenty-four are selected, even from a large garden or nursery.

I hope this question, which may possibly have been mooted elsewhere, will be thoroughly discussed in THE GARDEN, as I think it is an important one for the future of the N.R.S.

CHARLES J. GRAHAM.

Weylandts, Leatherhead.

NEW AND RARE PLANTS.

ZEPHYRANTHES AJAX.

THIS is said to be a hybrid between *Z. candida* and *Z. citrina*. It is figured and described by C. Sprenger in the *Gartenflora* for December, p. 649, where it is stated the plant is intermediate between its two parents, but harder than either, and that it flowers profusely in late autumn. The figure represents a tuft 6 inches high of rush-like leaves and a dozen flowers over 2 inches wide, coloured lemon-yellow, flushed with rose outside. In appearance it resembles *Z. candida* in every particular except colour, and if it be really as hardy and floriferous as that plant it is a valuable acquisition. *Z. citrina* was introduced by Messrs. Veitch in 1881, and figured in the *Botanical Magazine* (t. 6605), where it is described as a distinct species allied to *Z. candida*, but differing in the form and golden-yellow colour of its flowers. I have never seen a living example of this plant, and I think it just possible that *Z. Andersoni* (*Habanthus*), a common yellow-flowered species, and not *Z. citrina*, is the other parent of this new hybrid. Mr. Sprenger is quite right when he says that the genus is much more useful in the garden than is commonly supposed, and that if its hardiness were better understood it would be much in favour. At Kew, *Z. candida* is used as an edging for flower borders in place of Box.

KALANCHOË FLAMMËA.

SEEDS of this, perhaps the best new plant of last year, are offered by Messrs. J. Veitch & Sons, who, by an arrangement with the Director of the Royal Gardens, Kew, have secured the whole stock of this new species of Kalanchoe, recently introduced from Somaliland, in East Africa. Its cultivation is of the simplest, provided one or two essential conditions are observed. These are: First, the plant requires full sunlight at all times, a stove temperature for the first 6 months, greenhouse afterwards;

second, the seedlings should not be stopped until they are 6 inches high, and then they should be cut down to within 2 inches of the soil; after this they should not be stopped again; third, the soil best suited to them is a mixture of loam, peat, and leaf-mould; two parts of the first to one each of the other two, and plenty of sand. During winter they should be kept on the dry side. Under proper treatment seeds sown in February should produce plants to flower in about 15 months.

CRESTED BIRDS-NEST FERN.

THE only plant known of this remarkable Fern was introduced to Kew from Queensland two years ago, and as it bore ripe spores a sowing was at once made, from which a large batch of plants were raised. These have grown into nice plants, and a large proportion, probably 50 per cent., have developed the character peculiar to the parent, namely, fronds which, instead of being strap-shaped and simple, are branched or lobed so much as in some cases to be distinctly bi-pinnatifid. The type, *Asplenium Nidus*, is now one of the most popular of Ferns for use in room decoration, thousands of it being disposed of annually by some of the principal London market growers. It is therefore probable that the new variety may also find favour as a commercial plant. Botanically it is interesting, because of its being a wild sport which has reproduced its peculiar characters from spores.

BEGONIA HEMSLEYANA.

CHINESE plants are now objects of more attention than formerly, several collectors being engaged in sending new and interesting plants from the interior to England. One of the most energetic in this respect is Dr. Henry, who has discovered and sent to Kew many interesting plants, including the beautiful *Lilium* named in compliment to him. A plant of less intrinsic merit than the *Lilium*, but still of interest horticulturally as well as botanically, is this *Begonia*, which when not in flower might easily be mistaken for a Hellebore. It forms dense tufts of palmately divided dark green leaves, on stems about 1 foot, and produces erect, few-flowered scapes of pink flowers. In view of the value the Socotran *Begonia* has proved to the hybridist, this Chinese introduction is worth attention. Sir Joseph Hooker says of it: "The discovery of a palmate partite-leaved *Begonia*, the Old World, is a very remarkable one, the few known species with this character being all American." It was found at an elevation of 5,000 feet in Yunnan by Dr. Henry, who described it as a very pretty plant 1½ feet high. It flowered freely and continuously at Kew in a greenhouse from April onwards.

DIANTHUS SUPERBUS CHINENSIS.

A COLOURED plate of this plant was published in THE GARDEN last year (May, p. 330), when it was suggested that the plant was probably a perennial, as it had survived the winter at Kew. This autumn, and on until the beginning of December, the same plant flowered most profusely, the stems being again 1 yard high, forming quite a sheet of grassy-green leaves and starry rosy-mauve flowers 2 inches across. It is totally distinct in character from all other pinks, and is in every sense a most effective hardy plant. As stated last year, it has lately been introduced from Central China, by means of seeds collected in Shensi by the Rev. Preech, a missionary there. In addition to its own merits as a hardy border subject, this plant, which is probably like all other pinks in their readiness to cross freely, may prove the progenitor of a race of hardy late autumn-flowering sorts. It is worth the experiment.

MUSSELENDIA CAPSULIFERA.

AS represented by a figure in a recent number of the *Botanical Magazine* (t. 7671), this has failed hitherto to attract the notice of horticulturists. It is, however, not unlikely to find favour, if only on account of the delicious odour of its white

Jasmine-like flowers; probably, too, it will prove a pretty little flowering pot-shrub when its requirements are better known. It comes from the island of Socotra, where it was found by Dr. Balton at the same time as *Begonia socotranica*, but it was not introduced until two years ago, when the late Mr. Theodore Bent visited the island and brought home seeds of it, which were sown at Kew, where plants flowered in April last. It forms a leafy, compact shrub, suggestive of a *Hypericum*, the leaves being lanceolate, dark green, and 2 inches to 3 inches long. The flowers are produced in erect terminal corymbs, and they are like those of *Jasminum grandiflorum* in size, shape, and whiteness; they remain fresh on the plant a week or more, and, as already stated, they are deliciously fragrant.

HIDALGOA WERCKLEI.

THIS is a new plant of more than ordinary promise. It is a quick-growing climber, self-supporting, with numerous drooping branches clothed with evergreen elegant ternately divided bright green leaves. Even as a climber for draping pillars, &c., in conservatories, and probably also for growing outside on verandahs, &c., in summer it would prove of value, and in addition to its leaf attractions the bright scarlet flowers, 2½ inches across and resembling single Dahlias, are freely produced. A small plant received at Kew, and placed in a cool house in April, grew freely and flowered in July, and it is now 12 feet long, with numerous branches, some of which are now (December) bearing flower buds. It is easily propagated from cuttings. For its introduction we are indebted to Mr. J. L. Childs, the New York nurseryman, in whose catalogue a coloured picture of it was published, together with particulars of its origin, &c. These are to the effect that the plant was found in the mountains of Costa Rica by M. Carlo Werckle, and that in New York it has proved suitable for cool shady windows or verandahs, where it has received the names of Treasure Vine and *Childsia Wercklei*. The plant, however, belongs to the genus *Hidalgoa*, which is related to *Dahlia* and *Coccoloba*. There are possibilities in this relationship which hybridists might turn to account. A figure of this plant has lately appeared in the *Botanical Magazine*.

Royal Gardens, Kew. W. WATSON.

WINTER PROTECTION FOR OUTDOOR FLOWERS.

IT is well worth while to provide suitable shelters for the few outdoor flowers that we have in mid-winter. Of these one of the most important is the yellow Jasmine, so usually grown against walls, palings, or sheds. Either the rot-proof Willden canvas or a stout quality of the same scrim are excellent materials for protective coverings.

It is easy to have a sheet of this for each section of wall or space where it is likely to be wanted, and well worth the trouble of the slight preparation needed for taking on or off quickly. The sheet has a strong tape or webbing sewn to the top and a few stout rings, and the wall is provided with corresponding hooks, it is soon put up and taken down, and is easily folded up when out of use. If several of such sheets are in use, it saves much trouble to have them numbered; best by painting in white or grey a 3 inch square patch in one top corner, on which, when dry, a number in darker colour is painted, also painting the same mark on the wall, then there is no fumbling about or loss of time in finding out which sheet is for which place. Contrivances for keeping the sheets down in windy weather will suggest themselves to intelligent persons; but the great thing is to have the protection at hand.

A number of hurdles latched with straw or reed or heath are always of use to be put over Christmas Roses, or Uzar Violets, or Iris *stylosa*. The sweet bloom of any *Chimonanthus* trained to a wall shrivels and is spoilt in severe frost, but may be saved by hanging over the bush some boughs of Spruce or Scotch Fir. If the protecting boughs are hung up by their stem ends they are easily lifted or moved aside so that the flowers may be picked.

CORRESPONDENCE.

LOVE OR FASHION?

[TO THE EDITOR OF "THE GARDEN."]

SIR, We have boasted somewhat of the revival of the love of gardening in recent years. And as evidences of it we have pointed to the enormous increase in the cultivation of flowers for the London market, to the flower-sellers in the streets, to the profusion of flowers in house and table-decoration, to the almost universal use of real flowers for sprays on ladies' dresses, where ten or twelve years ago artificial ones would almost certainly have been employed. And there is no denying these things. The cut-flower trade of London, and of all large towns, is assuming a really gigantic proportion. Tons and tons of cut blooms come into London daily. The street-sellers bid fair ere long to become almost as great a hindrance to free traffic as the nursery-maids and perambulators.

The profusion of flowers in some drawing-rooms is so great that it is with difficulty one can pilot a safe course from one side to the other without being in collision with a basket or vase; and many dinner-tables are so overlaid with them that not a speck of tablecloth is to be seen, and not a vestige of a spot where a fan or an extra glass of water can be set. These things are undeniable. But do they really evidence an increased love of gardening, or even an increased love of flowers? By no means necessarily so. A man may furnish his library with the most expensive books, gloriously bound, but it by no means follows that he cares for the books as books, or loves to read them, study them, or pore over them. They may to him be merely so much of the furnishing of his house—the sort of things to have, you know! And I fear the present craze for flowers has in very many cases no truer basis. It does not spring from real love of the flowers, but from love of fashion and love of outdoing one's neighbour.

Looking back half a century I see comparatively very few flowers in the house, none at all upon the dinner-table; and a single *Camellia* or bunch of *Stephanotis* in the hair. But do not think that people cared less for their gardens or their flowers in that "long, long ago." Why, they loved them so dearly that they almost grudged to cut them for their personal adornment. They would gather one for a sweetheart or a friend, but hardly for themselves. Each country house had its bordering of flowers along its garden walks, and the mistress was wont to dissipate her household cares by personally caring for her flowers. Where are these old-time country ladies now? Now everything is left to gardeners; I daresay may, I know more flowers are grown; but do not tell me that it indicates an increased love of flowers.

I love my gardener. I admire him vastly; he is always at work toiling early and late in heat and cold, in wet and dry. He knows a hundred times more about the wants of the plants, probably than I. And all he needs is a hint now and then to prevent his going off in a wrong direction, or after a mistaken idea of excellence; but for all that he does not love the flowers as I do. A doctor may know far more about the children's wants than the mother does, but he does not love them as she does. Why has the vampire of size in flowers, fruits, and vegetables, been allowed to well-nigh smother out ideas of true fitness and proportion? Because the refinement of the

country lady's personal attention has decreased. Everything has been left to the gardener, and he has easily been led astray by the bugbear of competition without a single hint from master or from mistress that he was pursuing an altogether mistaken idea of excellence.

And yet I do believe the tide is turning, or has turned. More individual attention is being paid, more personal interest taken in, the gardens and plants themselves, and not only in the flowers and fruits that are got out of them. The craze the fashion may, the love of flowers and fruits will not easily decay; now we want to add to it a revival of the old-fashioned personal love of plants and gardens.

Shirley Vicarage.

W. WILKS.

[We think and hope that our kind friend the secretary of the Royal Horticultural Society underrates the strong growth that has of late years taken place in the love of gardening. For though there can be no doubt that just now it is the fashion to like flowers, or to pretend to like them, yet the number of people whose love of flowers and gardening one may test by the trouble they have taken to learn something about them, is truly astonishing, and seems to be ever on the increase. ED.]

BIRDS IN THE GARDEN.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Birds have been placed under the protection of Act of Parliament to enable them to increase and multiply and prey upon destructive insects, thus ridding our gardens of one of the gravest troubles which the gardener has to contend with. But gratitude seems to be a sentiment quite foreign to the ideas of the birds, and just as these plagues have, under protection, increased, so, in a like ratio, have the insect pests increased; thus, between the birds and the insects, allied to turgid attacks, the life of the gardener is becoming wretched. We have credited some of the hard-billed birds with a taste for the buds of Plum and other fruit trees, as well as of gooseberry and currant bushes, only when hard driven for food in severe weather. But the feathered depredators do not wait for frosts before they have begun their work, and already one hears complaints that the Plum and Damson trees, Gooseberry and Currant bushes, are being stripped of their buds, thus rendering them useless for next season at least. "We have acted on the best advice, and syringed the trees with soft soap, then oiled them with lime and soot, to render the buds obnoxious, but without avail. Accordingly destruction has come on all the same. What can we do to protect our trees and bushes?" Here is a common form of complaint, and it is the appeal of the gardener. What is the good of telling such men to try the common remedies when they have found them already useless? Shoot the little pests they may not. Sparrows, linnets, chaffinches, tom-tits, and many other birds seem to have realised that the law will not throw them over, and they are far more harmful than ever. What is to be done? Can it be recommended that we shall cover in all our fruit quarters in gardens with small mesh wire or nets to the utter exclusion of "those pretty birds"? Oh, the selfishness of man thus to suggest such a thing. Why may not the birds have their share? If they could be reasoned with by their uneducated admirers, and induced to leave fruit buds alone, and be content to take tithe of the fruit only, few would complain. But these creatures destroy the embryo fruit buds in their inception, and thus not only rob themselves of their share of the fruit but the aggrieved gardener of his share absolutely. Birds prefer vegetable tit-bits, such as are the sweet buds produced on fruit trees, the delicious points of germinating seeds, the soft green peas in pods not yet full-grown, and, not least, the fleshy sweet Pears and Apples and other fruits which they peck. We have had about enough of this laddism, and the Wild Bird Preservation Acts, so far as they relate to known depredators, must be revised.

What is the good of constantly urging our wider planting of fruit trees and bushes if the products of the labour are to be barren, arising from the foolish preservation of harmful birds. To get plenty of good fruit is more important and useful than is bird-pest preservation. The tad or sentiment has run wild long enough. Now is the gardeners' time for protection, and against nothing here at home does there seem greater need for such protection than against that intolerable trouble, the protected birds. A. D.

THE FIRST TOMATO GROWER.

A good deal has been written about the Tomato of late, and speculation as to its successful culture outdoors is being discussed; but the culture of the Tomato as a vegetable in this country, either indoors or out, is not such a recent affair as some seem to think. Tomatoes were grown both indoors and outdoors at Drumlanrig Castle, in Scotland, at the time of the Crimean War, about 1853 or 1854, by Mr. James McIntosh, the gardener there at that time. The reason probably was that Mr. McIntosh was rather fond of trying novelties. He grew, about the same time, good crops of *Passiflora edulis*, and, I think, *P. quadrangularis*, the Guava, the Egg-plant, and tried the Vanilla, but did not succeed in fruiting it. The Tomatoes were grown abundantly over the paths in the pine-stoves, and large quantities were cooked. They were then so acceptable to the cook that an attempt was made to produce a late supply out of doors. The plants for that purpose were grown on like the Dahlias in pots, and planted out in May against a close wooden paling about 200 feet long. They fruited, but few of the fruits ripened thoroughly, and about October the plants were pulled up with the partly ripened fruit on them and hung up in warm sheds to ripen.

I forget the botanical name of the Tomato then, but it was not "*Solanum*," and it was called the "Love Apple." The fruit looked so tempting that the writer was once induced to taste it, but he never bit another for a dozen years at least. Afterwards, when near Edinburgh, no Tomatoes were grown in any garden near there that I knew of, nor was it till long after that that it became common. Now-a-days it is as common as the Potato, and is in every greengrocer's shop and on every hawk's barrow.

J. SIMPSON.

A USEFUL VEGETABLE.

CELERIAC, OR TURNIP-ROOTED CELERY. This is a useful winter vegetable, but it is not so largely grown as it deserves to be; its value has long been recognised on the continent, and quantities are annually imported into this country, which always find a ready sale and realise good prices. The flavour is very distinct from that of Celery, and makes a most welcome change. The cultivation is simple; it will thrive luxuriantly on almost any well prepared soil. The seed should be sown thinly in pans early in March, and the seedlings pricked out as soon as large enough to handle, treated, indeed, precisely in the same way as Celery. By the end of April or early in May they should be transferred to their summer quarters. A south or west border should be selected if possible. Trench the ground or deeply dig it during the winter; no trenches are required, as it should be grown on the flat. Break the surface up before planting, make quite firm, and rake down level. Lift and plant with a trowel, allowing 2 feet between the rows and 18 inches from plant to plant. Like Celery it is a moisture-loving plant, and should be kept well supplied with both clear and liquid manure water during dry weather, keeping the soil constantly stirred with the hoe to promote a free, quick growth. Lift the roots before frosty weather sets in, trimming off the leaves and store in sand or ashes in the root room, when they may be taken out as required. These will generally last in good condition until the end of March.

EDWIN BECKETT.

A STREAM AMONG THE MEADOWS.

In quiet places of wood and hill and valley, one may often come suddenly upon some quite simple picture of flower-beauty, or of pleasant natural combination of form and line, or even of both together. In many a tract of meadow-land such a picture as the one here shown may be met with; of extreme simplicity and yet full of interest in detail, and with a grouping so broad and good that it is a practical lesson in what is known in painters' talk as "composition." It is April; the Alders are not yet in leaf, but the masses of their large red-brown catkins look solid against the sky. The level lines of the meadow give full value to the rounded masses of the Willows, whose young foliage is in the soft velvet-like stage of growth.

The trout stream comes gaily along, singing its charming ripple-song as it flows swiftly over its shallow, stony bed. Just now it is not a stream only but a garden, handsomely set with broadly-spreading patches of the Water Crowfoot, the earliest to bloom of the wild flowers of our pools and streams. In such a scene one sees the value, as a garden lesson, of the simple treatment of one

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR DECORATION.

IN few instances, at the numerous exhibitions held throughout the United Kingdom, are the flowers of smaller size met with, then only from the collections of those who know and appreciate their beauty. A change, however, has set in, and many interested in Chrysanthemums now at last see that in growing large exhibition blooms their display has been limited and an unsatisfactory result for a year's work.

A Chrysanthemum to find favour as a decorative plant must partake of certain features. In the first place it must be free-flowering, bushy, or branching in habit, and by no means tall. Colour is a most important point, and a good self-coloured variety has many advantages over one of varied shades, the decorative effect of the former being more decided. On the other hand, flowers of varying shades are less effective, and for conservatory decoration and cut flowers less valuable,

which flowers of the finest colour are obtained, and in which an unpleasant "damping" often seen in buds of an earlier kind is rarely noticed. A long season of steady growth is quite as necessary in the case of plants intended for decorations as for those cultivated for exhibition blooms, and it is fairly safe to assume that if the same share of attention be given to the decorative sorts as to the other group, the former would considerably benefit.

When the plants have made some progress in the early spring, say during March, pinch out the point of the respective shoots. This will have the effect of inducing lateral growths to appear, and a few of the strongest should be selected and grown on, rubbing out the weakest from among them. At this period the grower must consider the object in view. If bushy plants be desired, the shoots may with safety be pinched at each succeeding 6 inches to 8 inches of their growth, the last pinching to be carried out during the latter part of June. Plants treated in this way produce an immense head of charming flowers. If it be the wish of the grower to only produce a few dozen flowers of medium size, after the first pinching the plants may be left to make their "breaks" naturally. When housing the plants in the autumn avoid crowding, otherwise much of the foliage will be lost. Abundant ventilation is desirable at the same time, but care in this matter should be observed.

SELECTION OF VARIETIES.

A selection to meet the needs of most growers should embrace those sorts flowering in October, November, and December. The following are the most beautiful:

OCTOBER (Japanese sorts). Klondike, rich yellow; Clinton Chalfont, bright yellow; Gladly-Roult, pure white, very free; Nellie Brown, reddish-bronze; Rycroft Glory, bronzy-yellow; Source d'Or, terra-cotta; Eolides Precoces, bright crimson; May Mauser, creamy-white; Lady Selborne, white; Yellow Selborne, yellow; Yellow Source d'Or, bright yellow; Mrs. Wingfield, rosy-pink; O. J. Quintus, mauve-pink; White O. J. Quintus, pure white sport from last named; Queen of the Earlies, white; and William Holmes, crimson. **Pompons.** Sem Melanc, white; Crimson Precocite, bright crimson; and Vesuve, crimson red.

NOVEMBER (Japanese). Mlle. Lactois, pure white; La Nymphe, pink; Annie Cliban, silvery-rose-pink; Mme. Louise Leroy, white; Mr. Chas. E. Shea, light yellow; Phœbus, yellow; Mons. Chas Molin, reddish-bronze; Pallanza, rich yellow; John Shrimpton, rich velvety crimson; Vivand Morel, silvery-mauve; Western King, pure white; William Seward, rich deep crimson; Emily Salisbury, white; Soleil d'Octobre, emary yellow; and Mrs. Coombes, silvery-pink. **Lucifer**

Mrs. Geo. Rundle, white; George Glemy, pale yellow; and Mrs. Dixon, rich yellow. **Pompons.** William Westlake, yellow; William Kennedy, crimson-amaranth; Marie Stuart and Emily Rowbottom, both Anemone pompons, the former bluish-blue and the latter white.

DECEMBER (Japanese). King of Plumes, deep yellow; Taxedo, bronze; Golden Dart, rich yellow; Mme. Felix Perrin, pink; L. Gunning, white; Golden Gem, orange and crimson; Princess Victoria, creamy-white; Mrs. Filkins, pale yellow; Mrs. Carter, primrose; Alice Carter, reddish-bronze; Sam Caswell, pink; and W. H. Lincoln, yellow. **Pompons.** Snowdrop, white; Primrose League, yellow; Antonius, rich deep yellow.

D. B. CRANE.

WATER CROWFOOT (Najas) IN A MEADOW STREAM.

good thing at a time. The whole landscape is delightful, but the eye fixes on the flowery patches as strongly attractive incidents. In a garden one can never exactly copy Nature, but the more we gardeners observe her methods the better we fit ourselves for composing our garden pictures, and it in our rambles among wild places, when we come upon a natural combination that strikes us as pictorially satisfactory, we have acquired the power of seeing why it is right and why we feel it to be beautiful, then we may have the satisfaction of knowing that the mind has gained some grasp of such practical apprehension as will serve for the planning of beautiful pictures in our gardens.

One of the important things this meadow picture teaches is the value of the feeling of repose given by the level line. Gardeners generally err in being too fussy. The level line in the picture is always of value, whether in the larger areas of the landscapes of Holland or of our own fenslands, or the still greater sea-horizon or distant lake shore. The towering heights of the Alps are never so beautiful or so full of impressive dignity as when seen above the long levels of the plains of Lombardy.

Many varieties, too, bear flowers of fleeting colour, and no reliance can be placed upon them for blending or for effecting a good contrast, consequently they cannot be regarded with the same favour as those of a more fixed and certain kind. Hence, when making a selection, avoid those kinds lacking clear, bright, and lasting colour. Those sorts, too, which develop their flowers on long, erect footstalks have a distinct advantage. This characteristic is regarded with more favour where the flowers are used for large vases, now so popular for decorating rooms. Unlike the exhibition varieties, those of a decorative kind invariably possess a good constitution, and this feature is important where a large display is desired.

Many writers advocate later propagation for decorative varieties than that followed in the case of exhibition sorts. This advice is open to question. No doubt late propagation means a dwarfer plant, but then there is less time to develop a good specimen. Early propagation usually results in the development of plants capable of producing a few dozen blossoms of medium size, or a profuse display of useful sprays of flowers when the latter are not disbudded. Early propagation must necessarily hasten the production of terminal buds, from

Erica melanthera. While many of the Cape Heaths are proverbially difficult to grow, this is one of the least fastidious of its class, and is now flowering freely in the greenhouse. It forms a very dense, twiggy bush, and from the profusion with which it flowers the entire plant is simply a mass of its little pinkish blossoms, against which background the tiny blackish anthers stand out conspicuously. The flowers remain a long time in beauty, and have a faint though pleasing perfume.

GARDENING FOR THE WEEK

PRACTICAL NOTES FOR
AMATEURS.

CHRYSANTHEMUMS.

ALL who wish to attain success next autumn in the production of high-class blooms, whether intended for exhibition or for home decoration, must, if they have not already done so, lose no time in making a commencement. The plants must have a long season of growth, and from the first great care and attention must be given to ensure the building up of

must naturally do almost dormant for a few weeks after insertion in the cutting pots, the damage done to the young tender growth is more serious than many suppose; reject any that have the slightest trace of rust, and wherever the stock has been badly affected with this disease obtain a clean healthy stock elsewhere, after burning every particle of those which have been infested.

The cuttings should be struck singly in clean, well-drained thumb-pots, and the compost should consist of equal parts of light fibrous loam and well-decayed leaf-mould, with a liberal addition of coarse silver sand, sufficient to enable the water to pass away freely. The whole should be passed through a sieve with a half-inch mesh.

Thoroughly mix the ingredients together, taking care that the soil is in a moderately dry condition before use, after placing a little fibre taken from the loam over the drainage. The soil should be

work should be pushed along whilst favourable weather prevails. Trenching is necessary for all fruit trees, as it allows the roots to penetrate deeply into the soil out of the reach of drought in the growing season, and water can percolate through the soil more freely. When grown thus the trees become better established, and produce a larger quantity of finer fruit than those planted in shallow cultivated ground. The ground should be trenched about 2 feet deep, by placing the top spit at the bottom and bringing the bottom one to the top; the advantages are that the best soil goes to the bottom for the roots to ramify in and weeds are killed, whilst the bottom (I may say interior) soil is brought to the surface, where it can be improved by nature and cultivation.

Old mortar rubble and charred earth are valuable for dressing heavy ground, and these ingredients should be worked in as trenching proceeds.

VIEW IN MR. WILSON'S GARDEN. PLANTS BY WATERSIDE.

strong, solid growth, without which flowers of the highest excellence cannot be expected. I am of opinion that the Chrysanthemum cannot at any time be too strong and vigorous, especially in the younger stages of its growth, providing of course a proper system of treatment be afforded. How often one hears the remark during August and September, "My plants are not very strong, but the wood is well ripened." I am quite aware that well-matured wood is necessary, but I am also fully convinced one must have both to achieve the best results. The

SELECTION OF CUTTINGS.

is important. Choose strong, sturdy root cuttings if possible, but before doing so the old stools should be thoroughly fumigated to free them from every particle of green or black aphids. When the cuttings are infested with these, and they remain, as they

made firm, placing a small quantity of dry sand on the surface, part of which will find its way to the base of the cutting when inserting it with a small dibble.

Everything should be in readiness before taking the cuttings. Each pot should be correctly labelled as the work proceeds, the cuttings being well watered in with a fine rose watering pot, and placed without delay in the propagating pit. The cuttings should on no account be allowed to flag.

EDWIN BLOKETT.

Albion House Gardens, Elstree, Herts.

THE HARDY FRUIT GARDEN.

HARDY FRUIT TREES.

WHEN the ground was not prepared nor the trees planted at the best time—*i.e.*, in the autumn—the

Ground if not naturally well-drained should be made so artificially. Fruit trees are not a success in wet, stagnant soil.

The situation should be open to receive the fullest benefit from the sun, but sheltered from direct winds.

The best shaped tree is the dwarf pyramid and bush for such kinds as Apples, Plums, and Pears. Such trees are more easily managed than standards, whilst they do not get so much damaged by wind, neither is the loss of fruit so great from the same cause. Twelve feet apart is a suitable distance to plant, more or less, according to the vigour of the variety and the kind of stock used at the time of grafting, whether of free or dwarfing influence.

Planting should be done when the ground is neither very wet nor frozen; this applies to all kinds of soil. Some sandy soils dry quickly after rain,

while others of a heavy nature are the reverse. The hole should be a little wider than the spread of roots of the tree, and the highest roots should be 3 inches or 4 inches beneath the surface. Slightly shorten with a sharp knife the broken ends of the thickest roots, put the roots out straight, work the soil amongst them, and make all firm.

After planting put a strong neat stake to each tree, and finish with a mulching of farmyard manure.

PLANTING BUSH FRUITS.

Ground between fruit trees may be cropped with small fruits or vegetables. If the former, a distance of 6 feet apart should be given to Red and White Currants and Gooseberries, and 8 feet or 9 feet for Black Currants.

Raspberries should be 6 feet between the rows and 4 feet from cane to cane in the rows. At the time of planting, shorten the canes to within 1 foot of the ground so as to throw all vigour into suckers to form canes, and to bear fruit the second season after planting.

G. NORMAN.

The Gardens, Hatfield House, Herts.

KITCHEN GARDEN.

At the beginning of the year the work in this department will consist chiefly in preparations for later crops. That sharp short spell of wintry weather in mid-December will have enabled the cultivator to wheel manure on the land, and this may now be dug in. Trenching the soil, especially in old gardens, is necessary. Although, by constant cropping, the soil may be considered in workable condition, it is not so, as it naturally needs a rest, and the introduction of new soil is a great gain, and will often do more good than quantities of rank manure. On the other hand, all soils cannot be treated alike, and any advice given may be beneficial. Bringing up poor, inert soil to the surface, and burying the old top layer too deeply, would be worse than merely surface digging. In such cases the old top soil must be retained, and deep digging practised, turning the surface up roughly, and allowing the weather to mellow and sweeten it. I will briefly touch upon the need of making unsuitable land more fertile, as one often hears that it will not grow certain crops; but frequently with a little assistance the soil may be made suitable. No better time of year can be chosen to do this work, providing the weather is suitable, than the present.

DRESSING SOILS.

It is not sufficient to place quantities of animal manure on the land. This practice may suffice in some cases, but not in all. For instance, I have had two or three kinds of soil in one garden, and these need very different treatment. In heavy clay land add burnt refuse, road scrapings, wood ashes, in fact, anything that drains or lightens; and with very light soil resting on gravel larger quantities of manure are needed. Dig as deep as possible, but keep the top soil on the surface. Again, the soil, as in the case of old gardens, may be badly infested with wireworm, which needs strong measures to eradicate. Frequently, however, one imports the enemy quite unintentionally. A few years ago I saw the top soil of a pasture used to improve a poor kitchen garden soil; the latter, though heavy and poor, was clean, whereas the soil brought in teemed with wireworm, and in its new quarters spread alarmingly, attacking the roots not only of vegetables but even Strawberries. Soils of old, worn vegetable quarters may be greatly improved by dressing with lime and gas lime to kill wireworm and prevent chubbing in Brassicas.

FRENCH BEANS.

French Beans should not be forced until the new year, as it is difficult to set the bloom. Some forced vegetables lack flavour, but this depends greatly upon temperatures. Dwarf Beans fortunately retain their good flavour when grown in heat, if well looked after, and from this date to the end of May it is not difficult to have Beans in quantity. Of course, at the last-named period, only cold frames are required. Only those kinds that bear abundantly and are dwarf and quick in growth should be used. A variety named Sutton's Foreing, also Progress and Early Favourite, are excellent for pot

culture, and to these may be added Syon House, No Plus Ultra, and Mohawk. I use rather small pots at the early part of the year, as quick growth is important, and 6-inch and 7-inch pots are quite large enough, using a light, rich soil, and placing the pots in a warm place for the seeds to germinate. After that, place near the light, and in a genial, most temperature not less than 65°. Sown every three weeks, a supply will be maintained.

Syon Gardens, Brantford. GEO. WYTHES.

WORKERS AMONG THE FLOWERS.

As the editors of THE GARDEN tell me that they propose to give a note on the doings and experience of some amateur working gardeners, and suggest one on mine, as a humble member of the fraternity I am happy to give it. My first work was with an orchard-house. My sister, whose good garden adjoins my cottage garden, was inspired by one of Mr. Rivers's early books to put up a large orchard house. Seeing that this suc-

G. F. WILSON, F.R.S., V.M.H.

ceeded, I put up, about forty-five years ago, one 60 feet by 20 feet, but being then a hard-worked man I had to prime the trees by candle-light. The rafters had proverbs, principally Spanish ones, pasted on them. An amateur asked Mr. Rivers how it was that his fruit was eaten by wasps while Wilson's escaped! The answer was, "How could they attack it with all these proverbs against stealing overhead!" I grew many sorts of good fruit, and got a first prize for early Pears, against thirty-six competing dishes, at the Crystal Palace show. The next move was at a sale at Stevens's, where there were some lots of Japanese Lily bulbs, supposed to be sea-damaged. The old stagers looked askance at them; I had hopes, and bought lot after lot of fifties, cut down wine cases, planted, and put them in the orchard-house; these turned out well. Among them, a beautiful Lily, allied to *L. elegans*, but of much stronger growth, and with a beautiful gold band in centre of petals, was named *L. Wilsoni*. Another Lily was a grand form of *L. longiflorum*, which M. Max Leichtlin named *L. longiflorum Wilsoni*, but I now believe it to have been the true eximium,

This success led me to take up Lily growing both in the house and in the open, and Canon Ellacombe named me "Lily Wilson." I received twenty-five certificates from the floral committee for Lilies shown for the first time. There was, besides, a successful rockwork in the cottage garden.

On retiring from business, I was able to attend the meetings of the Royal Horticultural Society's Committee, and was made chairman of the fruit committee, and afterwards of the floral committee, so I had means of knowing what was going on. In 1878 I had the chance of buying Oakwood, at Wisley (where heathy land is not worth, as it is here, £1000 an acre), a farm of about sixty acres, with an old oak wood and many sorts of soil.

My business work having been mixed up with many experiments and inventions, this place gave just what I wanted, a grand new field and plenty of work. The wood had not been disturbed for many hundreds of years, during which time oak leaves and bracken decaying had made a great depth of vegetable soil. This, with the light loam of the hill, gave great capabilities.

Rhododendrons and many other such plants grow vigorously and look after themselves. With a mixture of loam Lilies are happy, and in beds in full sun the early Irises, Calochorti, Ixias, and many bulbs liking hot places flourish. Iris Kämpferi having succeeded on the banks of our ponds, and now, having a rather damp six-acre field of good soil, we made a wide winding ditch, planting these Irises in damp soil. These were beautiful, so we have made a larger, wider ditch from which we have great hopes for next year. Gardening friends have spoken very kindly of the Wisley Garden. In a note in the *Gardeners' Chronicle* of 23rd June, 1883, one of the greatest plant authorities, Canon Ellacombe, wrote: "I saw it first three years ago, and thought it a very pleasant but not a very hopeful experiment. When I saw it last year I was astonished at the progress made, but I was still doubtful of its general utility. I had the pleasure of seeing it again last week, and must confess that it is a great success." Another great gardener who has a beautiful and successful garden of her own, on going round with me, said: "I don't know what to call this place, it is not a garden," and on my assenting to this, said, "I think it is a place where plants from all parts of the world grow wild," this being what I aimed at, was very comforting.

GEORGE F. WILSON, F.R.S., V.M.H.

Heatherbank, Weybridge Heath, December 15, 1899.

[In this slight and very modest sketch of what he has done, Mr. Wilson gives no idea of the great services he has rendered to horticulture. For, though he speaks briefly of Lilies and Japanese Irises, he makes no mention of the thousands of plants and shrubs from all parts of the temperate world, planted in different soils and aspects for experimental culture; of the large seed-beds of alpine and border plants; nor of the wide plantings of the many beautiful things that make his woodland and hillside at Wisley not only one of the most interesting gardens from the experimental point of view, but, region by region, one of the most pictorially beautiful. Neither has he said a word about the many articles, letters, and notes constantly contributed to the horticultural press, recording almost every stage and incident of his garden work. Of his unflinching and helpful kindness to the groping amateur, there must be thousands who would gladly express their gratitude. (Ed.)

GARDEN DESTROYERS.

DESTRUCTION OF PESTS
AT THIS TIME.

AT the turn of the year it is incumbent on all actively engaged in horticulture to think over what remains in the way of work that is best done in the winter that has not yet been put in hand, and at once to take steps to carry it out, as the spring work will soon force itself on their notice. Among the most important work that should be done, and which cannot be effected at any other time of year, is the destruction of certain insects which are now in a position to be dealt with in a manner that is impossible later on, when the buds begin to open, and the insects themselves are in more active condition. The members of that destructive family, the

SAW-FLIES.

which attack the plants in our gardens, are more easily exterminated in the winter than at any other time of the year, as they are then in the chrysalis condition in the earth beneath the plants on which the grubs have fed, and they can easily be destroyed by removing the earth to the depth of 3 inches or 4 inches, and killing the chrysalides that are in it. To do this effectually, the soil should be burnt or spread out somewhere, so that poultry can scratch it over, and pick out the chrysalides. If either of these ways is not feasible for any reason, the soil may be buried not less than 1 foot below the surface, and the ground above made tolerably firm, so that the saw flies, when they make their way out of the chrysalides, may not be able to reach the outer air, and fly to the plants on which they wish to lay their eggs. When the grubs drop from the bushes, they do not crawl far, but at once bury themselves, so that it is not necessary to remove the soil for any distance beyond the tips of the shoots. In the case of Pear trees, against a wall, that have suffered from the attacks of those grubs known as

SLUG-WORMS.

it would only be necessary to remove the soil for about 6 inches or 8 inches from the wall and for the length of the branches. With Gooseberry bushes planted in rows there would be of course a considerable quantity of soil to move; still, the trouble of taking it away and replacing it with fresh earth would be amply repaid by the bushes not suffering next season from an attack by these grubs. The soil round Rose bushes which have suffered from the attacks of these pests should be treated in the same way. Picking off the grubs by hand, or syringing with an insecticide, is not so effectual. Another insect which can be more easily combatted in the winter than when the leaves are on is the

AMERICAN BLIGHT.

which is one of the most destructive pests to Apple trees. If the trees are espaliers or cordons, they should be carefully looked over, and wherever the least sign of the insect can be found, that part of the branch or shoot should be well wetted with methylated spirit, applied with a camel's-hair brush or a solution of paraffin emulsion. If the tree has been so long infested by this insect that swellings and cracks are present in the bark, cloths of some description should be placed under the tree, and the loose rough parts of the bark be scraped off, carefully collected, and burnt. Well scrub the parts where the insects are with a stiffish brush dipped in a solution of paraffin emulsion, or some similar insecticide. When a tree is so large that it is almost impossible to reach all the parts infested by this insect, the tree should be sprayed with a caustic wash, which should be made as follows: Dissolve 1 lb. of caustic soda in half a pailful of water, then add $\frac{1}{2}$ of a lb. of pearlsh; stir the mixture until it is dissolved, and pour it into a vessel containing 10 gallons of water; then add 10 oz. of soft soap that have already been dissolved in a little boiling water; stir again

thoroughly, and the mixture is ready for use. It is not only most efficacious in killing all kinds of insect life, but also cleanses the trees from any moss or lichen that may be growing on them. As this mixture is very caustic, due care should be used to prevent it getting into the hands and clothes more than is necessary, and when using it wear a very old suit, and stand with one's back to the wind if possible; also choose a calm day for the purpose. The mixture should be applied with one of the knapsack spraying machines, or with a syringe, or garden engine fitted with a nozzle for making a fine spray. Every part of the tree that is likely to be infested with the American blight should be well wetted with the mixture. It is not safe to use this insecticide after the buds show any signs of bursting. Dead leaves only too often afford a good and welcome shelter to many garden pests, and as they give an untidy appearance to a garden there is no excuse for leaving them lying about under trees and in sheltered places as is so often done. Some of our most

INJURIOUS CATERPILLARS.

often pass the winter snugly curled up in a dead leaf. If the leaves are not wanted for leaf mould, they should be collected and burnt; if they are, they should be made into a heap as early in the winter as possible. When the refuse and remains of any crop are being removed, if the crop has been infested by any insect or fungus, they should not be thrown into a rubbish heap, but burnt, for the mild heating process that takes place on such a heap does not in any way injure many pests, either animal or vegetable; and when the contents of the heap are used as a dressing, these pests are ready at hand to attack the next crop that is planted. The

ROOT EEL WORM.

for instance, has been known to live for two years in a perfectly dry condition, and the resting spores of the finger and toe fungus are also capable of remaining dormant for the same time, or for even a longer period. The seeds of many weeds also are spread over gardens in the same manner, so that to my mind a bonfire in a garden is a much more useful institution than the often much-vaunted rubbish heap. The

LACEY MOTH (*CLISOCAMPA NEUSTRIA*).

whose caterpillars are so injurious at times to the foliage of apple and other trees, is one of the insects that can be better dealt with in the winter than at other times, for the females lay their eggs in such a manner that they are easily detected. Small bands, consisting of several rows of these eggs may often be found encircling the shoots of fruit trees, like a bracelet. These are the eggs of this moth, and if a tree can be freed from them there will be no chance of its being attacked by the caterpillars the next season, as it otherwise most certainly would have been. When these bracelets are picked off they should be carefully destroyed, and not merely thrown on the ground, where they will in due time hatch, and the caterpillars will very probably find their way to their trees. When beds and borders are being dug in the winter, a good look-out should be kept for any chrysalides that may be turned up. A slight blow with the spade or fork will destroy them, and the destruction of one chrysalis means one brood less of caterpillars later on. All the prunings and clippings from any plant that has been infested by any pest should be collected and burnt, and not allowed to lie about on the ground, near the plants. The winter is also the best time to cleanse fruit trees in orchard houses from the

TORTOISE SCALE.

that often infests them. The scales should be rubbed off with a stiff brush or a piece of coarse flannel, or canvas dipped in soft soap and water. All the branches and shoots should then be syringed or painted over with paraffin emulsion diluted with ten times its volume of water, for there are probably many young scales that are very small scattered about the tree that should be destroyed. If the trees are fastened against a wall or trellis, so that both sides cannot readily be got at, they must be

unfastened, for the branches must be treated on both sides alike. When they are replaced, new fastenings should be used, as pests are often harboured in old ones. The walls should be relime-washed, and the trellis newly painted or thoroughly cleansed. Vines, also, during the resting period, can be more easily freed from such insects as

MEALY-BUG AND SCALE INSECTS.

than at any other time. To rid vines from these pests, the rods and canes should be scraped with a blunt knife or some similar instrument. This scraping process should not be carried too far, or the insecticide used afterwards may prove injurious; it is only necessary to remove the loose bark, which might act as a shelter to the insects. The scrapings should be collected and burnt. To facilitate this the vines should be painted over first with a lather of soft soap and water, as this will prevent anything that is removed from falling about. While thus going over the vines it would be useful to have a small bottle of methylated spirit and a small brush handy, and to thoroughly wet with it any part from which any of these pests have been removed. The young ones and eggs are not always visible because of their small size. The vines should then be dressed with one of the following insecticides: Paraffin emulsion diluted with ten times its volume of water, or three parts of clay and one part of tar well mixed, and enough water to form the mixture into a paint. The walls should be well lime-washed, and all the wood and ironwork scrubbed with soft soap and water. There is an erroneous idea that a cold winter is very detrimental to insect life. This is by no means the case, and I do not know of a single instance in which it is true. Experiments have been made with the grubs of certain insects, which were frozen so hard that they could be snapped in two. A number were destroyed in this manner, whilst others that were allowed to thaw again seemed none the worse for the treatment.

G. S. SAUNDERS.

WINTER MOTH AND ITS
DESTRUCTION.

THE winter moth on our greased lands on fruit trees has been more than we have had for several years past. We were led to hope, from last year having less than a tenth of the usual quantity, that our annual landing had lessened their numbers. There seems something in the Wisley garden which suits them; in neither of our Weybridge gardens we find enough to make it worth while to have the cost and trouble of protecting the trees.

GEORGE F. WILSON.

Heathbank, Weybridge Heath, Surrey.

POLYGONUM BALDSCHUANI-
CUM.

THE demand for this beautiful hardy climber is far in excess of the supply, and is likely to continue so for some time unless some readier means of propagating it are discovered than we have now. The seeds distributed last year were failures everywhere, so far as records show; cuttings of young wood failed to strike, and those of older wood, tried in some gardens, were unsuccessful. I am told by one who succeeded that pieces of the old stems which have stood the winter out of doors will strike if placed in a warm frame in March or April. I believe layering in the same way as answers in the case of *Lapageria* will prove the best plan. The growth the plant makes is extraordinary. A small piece planted at the corner of a house in the spring in Cornwall had become a large mass by the autumn, and flowered freely. The plant was discovered by Regel, in 1883, on the banks of a river in Bokhara, at an elevation of 1200 feet to 1700 feet, and figured in the *Gartenflora* in 1888. It first flowered at Kew in 1896, and was figured in the *Botanical Magazine* the year following. It is perfectly hardy at Kew, where it has formed a Bindweed-like mass of perennial stems 6 feet high. It is said to grow to a height of 20 feet. It bears in summer large panicles of small white flowers, which gradually change to rose, and are succeeded in autumn by reddish fruits.

ORCHIDS.

CULTURAL NOTES.

NOTES which will appear under the above heading will possibly be at variance with the experience of many of THE GARDEN readers, but it should be borne in mind that the majority of Orchid collections are confined to certain areas, such as in the neighbourhood of London, Manchester, and large manufacturing districts, where poisonous fogs and smoky atmospheric conditions are present for the greater part of the year. I therefore propose to devote particular attention to the above-mentioned circumstances.

In Orchid culture, like all other branches of horticulture, suitable conditions should be provided. If a certain position in the house does not appear satisfactory try some other, either by suspending the plant nearer the glass or by placing it on the staging. In my experience I know many instances in which a change in the position of plants has had the desired effect. There can be no hard and fast lines in the culture of Orchids any more than in the case of other plants.

SOME ORCHIDS IN FLOWER.

The month of January is perhaps one of the duller seasons of the year, both as regards plants in flower and the work in the different divisions. With the exception of *Cattleya Triana*, *Cologyne cristata*, a few *Cypripediums*, and the early-flowering *Dendrobiums*, very few flowers are open. In the warm division, the flower-spikes of the *Phalanopsis* and developing, and will need constant attention to prevent them coming in contact with the roof glass. This is most important, because when very near to glass they are liable to be affected by sudden changes in the outside conditions. Though not apparent at the time the ill effects develop at a later period, and the results are unsatisfactory. I find that it is wise to lower those plants suspended by bringing into use small wire hooks to place them in the desired positions. When the plants are on the stages the spikes should be secured by tying them to a firmly fixed stick, and thus drawing them out of danger. During dull weather, or when excessively cold,

WATERING.

needs considerable care. The fact of the flower spike developing necessitates the plants being kept fairly moist at the roots, but sometimes excessive moisture would be detrimental. It is a good plan to give water early in the day, as then excessive moisture can drain away. When watering dip the plants sufficiently deep to cover the potting compost, thereby thoroughly saturating the material, but take care to prevent the water getting into the axils of the leaves. Allow the plants to become quite dry before water is again given. The water used also must have attention. After showers or heavy rains the water in the tanks will be found much colder for several days than the temperature of the house. This being the case, procure hot water to add until the water to be used is raised to the desired temperature. The bulk of the deciduous

DENDROBIUMS.

which include *D. Wardianum*, *D. aurum*, *D. nobile* in its many and varied forms, and the numerous hybrids of the *D. Ainsworthii*, *D. splendidissimum*, and *D. endocharis* sections, that have been placed under cool conditions for resting purposes, are now getting into forward condition. Extend the flowering season as long as possible, and the most advantageous way of procuring this is to select at intervals the most forward plants and place them in more growing quarters.

It is not advisable to remove the plants from their resting quarters and to place them immediately into the hottest house. This change must be brought about gradually by first placing the plants into an intermediate temperature and then

conveyed into the position where they may be allowed to flower. Only sufficient water should be afforded until the flower buds are formed, after which more liberal treatment may be given. All the available light should be afforded, and a liberal amount of humidity in the atmosphere maintained. But the latter must be subject to the outside conditions and the temperature of the house.

Cumhuri.

H. J. CHAPMAN.

SOCIETIES.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE sixty-first annual general meeting of the members and subscribers of this institution will be held at Simpson's, 101, Strand, London, W.C., on Friday, January 12, 1900, at 3 p.m., for the purpose of receiving the report of the committee and the accounts of the institution (as audited) for the year 1899, electing officers for the year 1900, and for the purpose of placing sixteen pensioners on the funds, ten of whom will be recommended to receive the benefits of the institution without election, and the remaining six by votes of subscribers.

The chair will be taken by Mr. Harry J. Veitch, treasurer and chairman of committee, at three o'clock. The poll will open at 3.15 and close at 4.30, after which hour no voting papers can be received. The voting papers have been issued; any subscriber not having received a copy should communicate with the secretary. The annual friendly supper will take place also at Simpson's, 101, Strand, W.C., at 6 p.m. on the evening of the same day, when Mr. W. A. Bilbey, of Weybridge, will preside.

G. J. INGRAM, Secretary.

175, Victoria Street, S.W.

ROYAL HORTICULTURAL SOCIETY.

THE first meeting of the committees of the Royal Horticultural Society in 1900 will be held as usual in the Drill Hall, James Street, Westminster, on Tuesday, January 9, from 1 to 4 p.m. The Scientific Committee will meet in the library on the same day at 4 p.m.

NATIONAL ROSE SOCIETY'S CATALOGUE.

WE have received from the hon. secretaries the official catalogue of the society, which is something more than a mere catalogue, rather a guide to the selection of Roses for the exhibition and garden, with illustrations. All who intend to cultivate Roses for show should consult this catalogue, in which the various sections of the Rose are distinctly set out, and we may say that it is almost indispensable. Copies may be obtained by those who are not members of the society and extra copies by members, post free for 2s., of either of the hon. secretaries, the Rev. H. Holywood D'Ombraun, Westwell Vicarage, Kent, and Mr. Edward Mawley, Rosebank, Berkhamsted, Herts.

BRISTOL GARDENERS' ASSOCIATION.

THE fortnightly meeting of the society was held at Redland on Thursday, the 28th ult. A large number of members were present, and the chair was taken by Mr. Cary Batton, jun., in the absence of the president of the society (Mr. H. Cary Batton). The subject for the evening was "Mistakes in Gardening," introduced by Mr. Charles Lock, of Keynsham. The president kindly offered prizes for plants. Messrs. McCulloch, Raikes, and Ross were the prize-winners. Mrs. Cary Batton distributed the prizes.

THE ROYAL HORTICULTURAL SOCIETY OF IRELAND.

THE annual meeting took place recently, when the chair was occupied by Lord Ardikam, president. The report was read by Mr. W. H. Hillyard (the hon. secretary), and showed a falling off in

subscriptions of £52 8s. 11d. We hope this society will prosper in the future, and it will do so if the members take to heart Lord Ardikam's advice and increase the membership.

* * * Secretaries of societies are invited to send notes of meetings, exhibitions, and forthcoming events.

TRADE NOTES.

EARLS COURT EXHIBITION, S.W.

MESSES. JOHN LAING AND SONS, of Forest Hill, London, S.E., have been awarded the diploma and gold medal for the manner in which they carried out their contract during the run of the Greater Britain Exhibition.

We hope nurserymen will send their catalogues for advertisement, and may even be likely to interest horticulturalists. Their assistance will be greatly valued.

FORTHCOMING EVENTS.

- Jan. 9. Royal Horticultural Society. First meeting of the year.
- .. 12. Gardeners' Royal Benevolent Institution. Annual meeting at 3 p.m. Dinner at 6 p.m. (Simpson's, Strand).

NOTES OF THE WEEK.

Some good winter shrubs. The past hot season suited *Raphiolepis ovata*. It flowered well, and now its ripe fruit stands in loose upright grey-black bunches. The round leathery leaf reminds one somewhat of *Arbutus* and *Escallonia*. It is a neat-growing interesting shrub for a warm place under a south wall. Here it is grouped with *Rosemary* and *Japan Privet*, these three shrubs being among those that look at their leafy best in midwinter. The *Privet* is specially cheerful with its highly-polished sharp-pointed leaves, much like those of the smaller-leaved *Oranges*.

Are the berries of *Gaultheria procumbens* edible? MR. S. ARNOTT need have no fear in eating or tasting the berries of that interesting little Canadian plant, *Gaultheria procumbens*. It is a very common plant in the Canadian bush, covering the rocks in damp, shady places. The berries are largely used for flavouring sweets both in America and Canada, and also in some patent medicines. Unfortunately, the birds are very fond of the berries, and there are few if any left on the plants here as I write. G. R. T., *Cheshirefield*.

Passion Flower in bloom on New Year's Day. I beg to enclose for your "Notes of the Week" what is perhaps a record, viz., a couple of sprays of *Passiflora coriacea* cut in the open air on New Year's Day. This Passion Flower is usually evergreen here except in exceptionally severe winters. We have had some frost one night about ten degrees. I would like to draw attention to one fact respecting this plant which is, I think, not generally known, that is, that if a spray with well-developed buds be cut and put in water in a room the majority of these will expand, the spray continuing in beauty for a long time. I also enclose a fruit of *Physianthus*, one of several produced in the open air this season. It flowered most profusely, and in one instance I saw a butterfly caught by its proboscis in the flower and quite dead. GREENWOOD PIM, *Easton Lodge, Monkstown, Co. Dublin*.

Azalea Illuminator. This is one of the numerous hybrids obtained by intercrossing the little *A. amena* with some of the larger flowered Indian section. It is of a dense, twiggy growth, but the flowers are larger than those of some varieties of this class, and are entirely without the hose-and-hose character characteristic of *A. amena*. The colour is a kind of deep rosy magenta, and little plants in the greenhouse at Kew are laden with flowers. It should prove a useful kind for forcing. Though little known it is by no means new, having been awarded a first-class certificate by the Royal Horticultural Society about fourteen years ago.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

Questions and Answers. *The Editors intend to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITORS OF THE GARDEN, 20, Tavistock Street, Covent Garden, London. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper.*

Names of Flowers. Not more than six specimens, carefully packed, must be sent at one time. *B. B.*—1, *Chimonanthus fragrans*; 2, *Gaultheria procumbens*; 3, Rosemary.—*T. J.* *Taxus baccata aurea* (Golden Yew).—*Don.*—*Odontoglossum crispum* (very poor form).—*Senec.*—*Helleborus fetidus*.

Names of Fruit. Not more than six specimens, carefully packed, must be sent at one time. *R.*—Lamb Abbey Peppermint; 2, Cox's Orange Pippin; 3, Baumann's Red Winter Renette.

INDOOR GARDEN.

Cyclamens not flowering (ABBESS). It is not unusual for *Cyclamens* to be coming into flower if the plants be late. But when did you sow the seeds? Many amateurs think that these plants will flower from a spring or early summer sowing, just as Chinese Primroses will; but that is an error. Growers of *Cyclamens*, to have the plants in bloom before the end of the year, have to sow the seeds in August of the preceding year, and for plants to bloom after Christmas, early in September. Practically the *Cyclamen* must be treated as a biennial. The plants produce seeds freely in May, and therefore it is always possible to have new seeds to sow in the late summer. They should be sown in 5-inch pots filled with sandy soil, each seed being dibbled in singly and just buried, yet firmly pressed in. When germination takes place the young plants have ample room to grow.

Lily of the Valley (PRESTON). You may safely lift your Lily of the Valley roots and transplant them now. Select a site that is partially shaded by a wall or fence, but which is not full of tree or shrub roots. Trench it 2 feet deep, and burying down to the bottom soil, well mixing it with a good dressing of half-decayed manure. Then, when all the piece of ground is done, spread over it a good coat of that manure and well-decayed vegetable refuse or leaf soil. Fork that in, and as you do so, chop down with a small spade at intervals of 4 inches furrows 2 inches deep, and plant in the strongest of the rooted crowns, lifted from the old bed, treading them well down and covering with soil. Keep the weakest crowns to the last. Give during the summer occasional soakings of liquid manure.

Stephanotis in large border not flowering (M.). The large border may be the cause, as the roots having such an extensive run, shoots and leaves are produced at the expense of flowers. Curtail the border, and thus restrict the root run. A border about 4 feet square and 2 feet deep should suffice for a large plant. Of course it must be well drained, and so arranged that the water supply can be increased or diminished as required. At the same time some forms of *Stephanotis*, whatever treatment may be given, are shy flowering compared with others, and yours may be one of this class, in which case the most satisfactory way will be to root it out and plant a specimen of the Elvaston variety in its place.

Blue Gum losing its leaves (TOWN GARDENER). The plants may have been kept too wet or too dry at the roots; the latter is the more likely, but in all probability the loss has been caused by the heavy sulphur-laden fogs we have experienced in the London district, which, judging by your signature, has doubtless prevailed in your neighbourhood. The leaves of plants affected by the fog present the appearance of having been scorched. Many Australian plants, including all the species of *Eucalyptus*, are especially liable to be injured by London fogs.

Cannas resting (R. P.). Cannas of this class should not be kept quite dry during the winter, as the rhizomes, or underground stems are apt to suffer if too much parched up. At the same time they must not be kept very moist, but receive just enough water to prevent shrivelling. The pots must not be placed too near the hot-water pipes. Some of the varieties, with the finest flowers, especially the yellow-spotted kinds, have the weakest rhizomes, and are consequently the first to suffer if kept too wet or too dry during the resting period. If kept in the greenhouse the young shoots will make their appearance on the return of spring, when the plants may be divided if it is required to increase the stock, or they may, if necessary, be shifted into larger pots.

Fuchsias for greenhouse rafters (ENQUIRER). A selection of the best varieties would include General Roberts, a very long flower, with bright red sepals, and dark corolla; Monarch, nearly a self-red flower; Olympia, salmon-pink tube and sepals, and red corolla; The Shah, red sepals, violet-blue corolla; Mrs. Kundle, pink tube and sepals, salmon corolla; Mrs. Todman, white sepals, scarlet corolla; Alexandria, red sepals, white corolla; Phenomenal, bold flower, with large double purple corolla; Sir Garnet Walsley, double flower with plum-coloured corolla; Mme. Jules Chretien, double white corolla; Luster, very long white tube and sepals, scarlet corolla.

FRUIT.

Forcing Strawberry plants (MONA). It does not at all follow that because you have numerous Strawberry plants in 7-inch pots that you can force them with success. If the plants have filled the pots well with roots and have produced good stout leaf crowns, then you may have success. If such be not the case, then you may get no fruit. We should for early forcing have preferred plants in 6-inch pots, and they should have had in them very early runners. The soil should also be of good loam and decayed manure, and be very firm in the pots. In any case we advise you to put some of the plants into a frame for a fortnight, then shift them into a very moderately warm house for a couple of weeks, then get them on to shelves near the light in a warmer house to bloom and fruit.

Planting Raspberries (JUSTICE). It is a mistake in making a new plantation of Raspberries to use strong canes, as these seldom have the most fibrous roots. We prefer canes that may reach to about 4 feet in height and have plenty of roots. Then you may plant at any time, when the ground is moderately dry and devoid of frost up to the end of March, but it is always preferable to plant in the early winter if possible. If you prefer to do so fix in at each side of your garden quarter stout larch or oak posts, and drive in a line with those about 10 feet apart other smaller ones. To these secure as tightly as you can four stout wires at intervals of 12 inches, and then plant the canes against these in a single row 12 inches apart. Cut the canes down almost to the ground in the spring.

KITCHEN GARDEN.

Early Peas (S. T.). Few gardeners sow Peas in November, or indeed, before Christmas. They should be sown in January only, on a warm sheltered border, and close under a wall or other protection. For more open ground the second week in February is early enough. Two of the most early and best-flavoured varieties are Chelsea Gem, 2 feet high, and Gradus, 3 feet high. Both are wrinkled narrows. The first-named is the best one to sow under a wall or fence in January, as, aided by a few sticks to support it, the bloom is well protected. The chief difficulty in getting Peas into pod very early is the harm sometimes done to the flowers by late frosts. As a rule, even in the most favoured places, it is difficult to get Peas fit to gather outdoors until June. American Wonder will pod earlier in pots under glass.

TREES AND SHRUBS.

Overhanging trees (E. C.). You may cut off branches from a neighbour's trees that overhang your garden, but only in a line with your fence, and do so without his consent. But it is better to advise him of your desire, and ask him to do it. In the case of lopping large Elm and Lime, or, indeed, any other big trees, it is best to do it in February. Trees of huge size may be cut back to branches as big round as a man's body safely then, especially if some thin tar be coated over the surface of the cut portion to protect it from the weather. The stems will very soon begin to put forth shoots, and in three years there will be quite a dense body of growth and branches formed, quite hiding the stumps, and forming fine trees. We have seen many apparently dying trees brought into new life and vigour by this drastic treatment.

The Sea Buckthorn (Hippophae rhamnoides) not producing berries (R.). The Sea Buckthorn is dioecious, that is, the male and female flowers are borne on separate plants. Should it be a female, and no male or pollen-bearing plant is in proximity to it during the blooming period, the flowers are not fertilised, and consequently there are no berries. It is a shrub which is seen at its best in a mass or clump, and if half-a-dozen females are planted in a group, a single male specimen in the central position will be sufficient to ensure the production of berries on the whole of them. Unfortunately, till flowers are borne the male and female cannot with certainty be distinguished from each other, though, as a rule, the male is characterised by stronger habit and larger leaves, but this is not an invariable guide.

Propagating the double pink Bramble (J. P.). This Bramble is readily propagated, like most of the others, by pegging down the tips of the long arching shoots, and covering them with a little soil. They will soon root and push up shoots of their own, thus forming an independent plant in the same way as a Strawberry plant is produced on the runner. This way of increase may be often observed in the Bramble of our hedgerows and ditches, of which this pretty pink kind is but a variety.

Clematis indivisa mildewed (PERPLEXED). This New Zealand Clematis is in low-lying or damp districts liable to mildew. Take the plant in hand as soon as possible, pick off the worst leaves, and freely dust the entire plant with flowers of sulphur. This must be kept up till the disease is stamped out. If done at once many of your flowers may be yet saved. A free circulation of air encouraged by slightly warming the pipes, even if it is not required to maintain the temperature, will often ward off an attack of mildew. Is the border really well drained? as, if not, this may have a good deal to do with the matter, while *Chrysanthemums* under glass are often troubled with it, and it soon spreads to neighbouring plants.

Hydrangea paniculata grandiflora (R. M.). To obtain those huge pyramidal-shaped heads which make such a show towards the end of summer, the plants are cut back hard in the spring, and only from four to six of the strongest shoots allowed to develop, the rest being pinched off. During the growing season the plants are fed with occasional doses of liquid manure, and as their whole energies

are concentrated in such a limited number of shoots, the result is seen in the huge proportions that the flower-heads attain. Secure the shoots to suitable sticks, even before the flower buds appear, as if broken, the loss of only one head is an important consideration.

GARDEN DESTROYERS.

Ferns and Primulas dying (M. P.). The roots of your Ferns and Primulas are attacked by the grubs of the black vine weevil (*Otiorhynchus sulcatus*). As far as I know the only way of destroying these grubs is by uprooting the plants and picking the grubs out from among the roots, as insecticides cannot be made to reach them in sufficient strength to kill them, for the ground naturally acts as a filter. These grubs will also attack Begonias, Cyclamens, and other soft-rooted plants. The weevils are also very destructive to the foliage of many plants. Vines, Ferns, Dracenas, and other plants grown for their foliage are often much injured. The authors of these injuries are not often seen, as they feed only at night, hiding themselves so cleverly during the day that they are most difficult to find. The plants that they are attacking should be laid on their sides on a white sheet, and soon after dark a bright light should be thrown upon them. This startles them, and they fall as if they were dead. If they do not fall, the plant should be given a good jarring shake and be well searched. If the plant be of such a nature that it cannot be placed on the sheet, the latter must be laid under it. If small bundles of moss or hay be tied to the stem of the plant or laid on the soil at the base of the stem the weevils will often hide in them during the day. These traps should be examined every morning. The weevils are about three-eighths of an inch in length, and are nearly black in colour.—G. S. S.

Eggs on Apple tree shoots (YORK).—The so-called eggs on the shoots of your Apple tree are not eggs, but one of the scale insects (*Mytilaspis pomonum*), the mussel scale, a common pest on Apple trees, and so named from its resemblance in form to mussel-shells. When this insect comes to maturity it lays its eggs beneath the shell, and then dies, the shell remaining as a shelter to the eggs and young scales. Lather the affected parts over with soft-soap and water, and then scrape off the insects and the lather, and dress the parts with paraffin emulsion, one part to ten parts of water.—G. S. S.

CHRYSANTHEMUMS.

Good late white Japanese Chrysanthemums (R. S. K.). It is unfortunate that more attention is not given to the late-flowering Japanese kinds, more particularly those white or creamy white. Your mention of Ethel carries us back many years, but this is rarely seen now-a-days. L. Canning, which is a pretty paper-white sort, has been the popular December white variety for some years. Princess Victoria is largely grown, this being pale creamy white, with a green tinted centre. Western King, when propagated during May and June, develops large, pure white flowers throughout December. Mrs. C. Bown is another large white sort of Australian origin. Mlle. Therese Pankoucke is supposed to be the finest late white Japanese variety. The still popular Souvenir de Petite Anie is late, and in this case, as in other mid-season kinds propagation in the spring or early summer is essential. The selection may well conclude with Nivern, a flower of the purest white.

CATALOGUES RECEIVED.

Dobbies Competitors Guide. *Dobbie & Co., Rotterdam, N.B.*
Sweet Peas, Culinary Peas, Vegetable and Flower Seeds, &c. *Henny Eckford, Wren, Shropshire.*
Garden Seeds.—*J. R. Pearson & Sons, Chilwell Nurseries, Notts.*
Garden Seeds.—*Webb & Sons, Wardsley, Stonebridge.*

Flower and Vegetable Seeds. *Wm. Catbush & Son, Highgate, London.*

BOOKS RECEIVED.

"Fruit Farming for Profit" (4th edition). By George Binnyard, V.M.H., Maidstone, Kent. Price 2s. 6d., or free by post, 2s. 9d.

PHOTOGRAPHS AND NOTES. *We shall welcome very much any photographs and notes sent to us, and hope readers who thus give practical assistance in making THE GARDEN interesting and useful will give their full names and addresses, not necessarily for the sake of publication, but to enable us to thank them for their kind co-operation in our work.*

THE COLOURED PLATE. *In future the coloured plate will not be given weekly, only when some new or rare plant likely to create general interest is introduced. It will, however, always be given with the first number of each volume.*

ROSE MAISON DE SAISON. PT.

THE GARDEN.

No. 1469.—VOL. LVII.]

[JANUARY 13, 1900.

HORTICULTURE IN 1899.

A GAIN the march of time brings us to the beginning of another year and the threshold of a new century. Over the later months the cloud of war has hovered, darkening many a home in our wave-lapped isles and beyond the seas, but we who pursue the peaceful art of gardening are not unmindful of those brave sons fighting for their country's honour and glory and for our advancement. It is no uncertain sign of a nation's prosperity under severe trial when a horticultural year of conspicuous progress can be recorded, a year of commercial activity, and abundant evidence that, although horticulture receives scant State consideration, we are advancing steadily in improving its aspect in many ways—in fruit culture, hybridisation, to acquire greater variety of flowers and improved forms of fruit and vegetables, and in working out the principles of true horticulture.

Thus we commence our work upon *THE GARDEN*, knowing that a true spirit of gardening is made more manifest at this time than when the year that has closed was ushered in, and let us hope that this gardening spirit, a wholesome, healthful, and life-giving recreation, will extend its influence to the benefit of humanity. The British are a gardening nation, more so at the present age, perhaps, than in the early days of the Victorian era, and those who at one period considered the garden as a shop from which to draw daily stores, now find enjoyment in its poetic aspect, and grow the flowers and fruits with a keen sense of satisfaction in the knowledge that a world hitherto veiled in mystery is being explored and is yielding undreamed-of pleasure.

The hybridisation conference held in the Royal Horticultural Society's Gardens at Chiswick was a notable event, not merely of the past year, but of the entire century. When the horticultural history of the nineteenth century comes to be written, plant-hybridisation should form its most splendid chapter, and every month almost we receive gifts from those who have made this their especial study. In the hands of the hybridist, distinct and beautiful flowers and improved forms of fruits and vegetables are moulded, and our gardens made to yield a more bountiful produce. To those nurserymen and gardeners who have given to the world so many good things our thanks are due. Horticulturists from abroad came to this conference to take their part in an important

event which concerned not merely our own land, but the nations of the world, who have contributed to the storehouse of new and improved forms of plant life.

It is with no mixed feelings of pleasure that we see the Royal Horticultural Society pursuing its steady and correct course of true horticulture, and whilst its direction remains in the present hands, this policy will remain. When a society founded for the good of horticulture forgets its mission to indulge in showmen's tricks, then it is time to so reform it that a new organisation is practically raised upon the wreck of a false and unworthy constitution. The Temple show was again a complete success, financially and otherwise, and the fruit exhibition at the Crystal Palace was a remarkable display of British productions, which must bring strong influence to bear upon the fruit industry of this country. Whilst writing of the exhibitions of the Royal Horticultural Society, we must remember that other societies, too, have played a large and good part in the horticultural year—societies devoted to the Rose, Chrysanthemum, Auricula, Picotee, Dahlia and others, and we are thankful that greater artistic exhibits are displayed of the various flowers. It is becoming almost a pleasure to visit some exhibitions, where simple groups are arranged to show the true beauty of flowers, hitherto cramped into a set space or jammed together in masses. The object of an exhibition is not to put petals on a box, or to create splashes of colour by fuzzy muddling representations. Exhibitions have a great power for good, and it is a power that has not been used to the best advantage in the past. It is no unreasonable wish to expect a still greater development of the policy of remembering that a flower is a thing of beauty, and should be displayed to show forth that beauty in its fulness.

Gardens and nurseries suffered severely from the heat of the summer, and drought teaches gardeners wholesome lessons. Those who fail to thoroughly trench their soil, and therefore never provide a foundation for the roots to live upon in times of drought, will always grumble when rain is absent for weeks and even months.

The records at Greenwich show that the total rainfall for the year in the London neighbourhood was 22.1 inches, and this is less by 2.4 inches than the average. It is interesting and important to know that during the past seventeen years only three years have shown any excess. August was the driest month, the total measurement being 0.35 inch, and this is a record for the past sixty years.

Of the legislation affecting the Agricultural Ratings Act we shall have much to say in the future, also of the restrictions regarding the sale of insecticides and weed-killers. An attempt has been made to cripple or destroy an industry of importance to the trade and gardeners—unthinkingly perhaps, but that does not satisfy one's desire for reasonable consideration.

In many a gardener's home the Angel of Death has beckoned to higher realms the worker we knew and respected—some stricken in almost youth and in the prime of life, others after long and busy years spent for the good of horticulture. John Lee, a great nurseryman and supporter of the Royal Gardeners' Benevolent Institution, has gone, at the age of 94, and amongst other familiar and famous names must be mentioned Kelway, of Langport, Lord Pezance, Henry de Vilmorin, Francis Rivers, Charles Naudin, the French botanist and hybridist, T. J. Saltmarsh, William Thomson, W. H. Protheroe, Malcolm Dunn, prince of Scottish gardeners, Major Mason, A. Outram, and T. W. Girdlestone. Their good works will ever remain, for each in his own branch of horticulture achieved lasting results, as notices of their life-work in our columns at the time of their death have shown.

This restless age urges the younger horticulturists to follow in the footsteps of those good men whose earthly work has not been completed, but remains for others to take up and again hand down to future generations.

The names of many famous hybridists are recorded in this list. That great leader, Kelway, of Langport, has enriched English gardens with a hundred noble flowers—Delphiniums, Peonies, Gladioli, and other plants precious to the gardener; and of Lord Pezance one may write that his name will be perpetuated, not by judicial acts, but by the work performed in leisure hours in promoting a race of hybrid Briar Roses to perfume the English garden.

But many articles could be written upon all these worthy horticulturists, of that famous rosarian, T. W. Girdlestone, whose knowledge of Roses and charm of style are lost to *GARDEN* readers; Francis Rivers, of Sawbridgeworth, and Henry Martin, whose work amongst florists' flowers is written large in the greenhouses of the world. We mourn their loss, but are ever reminded of their good work by the flowers and fruits about us—memorials, ever tending to our pleasure and comfort.

GARDEN THOUGHTS.

CYCLAMEN COMM.

HERE is a fascination about the earliest flowers of the year which is difficult at times to account for if we compare their charms with those of the summer. It lies not in their brilliance nor in the size of the blossoms they display. Many of them have small flowers, and many have pale colours which seem akin to the faint sunlight which looks wanly upon them. To the former class belong the flowers of *Cyclamen comm.*, but it cannot be said that its blooms want for bright colouring. As this is being written the flowers are yet concealed from the passer's view. If, however, we raise the stems which ere long will bring them into view, we shall see, tightly packed in a spiral form, the flowers already showing the crimson-purple which looks so bright against the dark earth or, it may be, the snow, when they are in the prime of their beauty. One would think that this colour would have vanished before that time. Not so; the dyes which make up the colour of this Sowbread or Bleeding Num are less evanescent than the lovely, yet fleeting, tints given by our aniline dyes. When they are fully open these flowers will show no traces of having withstood the stress of all "the rough weather," as dear, quaint George Herbert puts it. It is little short of marvellous to see these pretty flowers so early in the year. Exquisite as are the marbled leaves of the Neapolitan *Cyclamen* at present, we can admire still more when they are open the blooms of the winter *Cyclamen*. We have no dearth of leaves, winter though it is, but flowers and, above all, flowers of this colour are dearer still. The leaves of *Cyclamen comm.* are dull and unattractive when compared with the others. Their flowers are no better, but then they come at a time when we are wearying to see them appear among the harbingers of the floral year.

It is a flower one would fain see more largely grown in our rock garden or in cosy nooks where it would not be hidden by rank growth of other plants. It is not difficult to grow in light soil mingled with leaf-mould. In these places and in such soil it will give much pleasure when it sends up its dark stems, from which depend I do not know that "depend" is a good word, but I cannot think of a better, the bright flowers. It is a quaint fancy which has called the *Cyclamen* the Bleeding Num, but it is a more grateful name to our ears than the old one of Sowbread, which may be true enough in some of its native habitats, but is unpleasant to those who grow it for its beauty. I prefer the typical flower with its crimson-purple blooms, but appreciated also are the white, the rose, and the lilac varieties which are to be had as well. One may, perhaps, have been thought too enthusiastic in thus writing in praise of this *Cyclamen*. It is not easy to write coldly or in faint praise of such gifts of the time. S. T.

SEDUM BREVIFOLIUM VAR. POTTSI.

I HAVE been favoured with several interesting and valued letters upon the cultivation of this pretty, but little-known Stoncrop. It is to be feared, however, that the diversity of experience they reveal is not particularly satisfactory to those who have had similar troubles to those the writer has experienced in attempting to grow it. It is, notwithstanding, pleasant to find that it can be grown with success under conditions of the most opposite kind. The correspondence with which I have been favoured shows in a marked degree the truth that success with many plants cannot be secured by following any one method. Climate must remain a factor which sets at defiance our impressions derived from other gardens.

The last remark is dictated by Mr. E. C. Buxton remarking, in reply to a suggestion of mine that possibly the wet climate here was the cause of the failure of this *Sedum* with me, that he found it could hardly be kept too wet in summer. He also pointed out that the rainfall in his district was

from 60 inches to 70 inches. This is a great deal more than we have here. This remark would probably have made one come to the conclusion that the wet was not the cause of the loss of this Stoncrop, had it not been that a note from a good friend in Roxburghshire informed me that he did not think that it was quite hardy there. This was followed by a second note, which told of the experience of Mr. Potts, the original introducer of it to our gardens in Britain. It appears that it is quite hardy in his garden at Lasswade, near Edinburgh, but that it requires to be protected from wet in winter by a plate of glass overhead. In North Wales it seems to enjoy all the rain it can get in a wet climate, while near Edinburgh in a dry district it needs to be kept dry in winter. It is all rather puzzling, yet encouraging to those who have lost it in the past. One is anxious that so pretty a Stoncrop should find its way more largely into gardens of choice alpinists. It may appear to some that a Stoncrop is too insignificant to trouble about. That will not be the opinion of those who have studied the beautiful colouring of the one under notice.

I am also glad to have had an opportunity of finding out something about the history of *Sedum brevifolium* var. *Pottsi*. It has transpired that Mr. Potts got it about twenty-five years ago from the Jardin des Plantes in Paris along with some others. It has probably another name, but it will not be easy to discover what it is. It has found its way into commerce in Britain under the above name, which associates with it the name of a good lover of flowers. S. AENOTT.

Carethron, by Dumfries, N. B.

HYACINTHUS AZUREUS.

THE little spikes of the pretty *Hyacinthus azureus* are now coming on as quickly as the weather will allow, and soon we shall see at their best the cone of flowers it gives. It is more like a Grape Hyacinth or Muscari than any of the other plants we grow as *Hyacinthus*, and it might, for purely garden purposes, have remained under its old name of *Muscari azureum*. It is in form a Grape Hyacinth and gives us the earliest hardy flower of the shape so familiar to all who care for the *Muscari*. It is not equal in beauty to some of the true Grape *Hyacinthus*, but then its earliness commends it in our eyes and makes one glad to see its flowers appear. It is quite hardy here, although some winters its spikes decay before the flowers open through the ice which forms at its base. This loss can be avoided by placing a piece of glass above the plants so as to throw off the rain. The worst enemy, however, that one has to face is the slug. It is exceedingly fond of the flowers just as they peep through the soil, and, if let alone, will soon destroy all one's hopes of a display of the soft blue flowers. This season some plants left unguarded by their zinc rings until too late are pitiful to look at and give one an oft-needed lesson of watchfulness and care being required in our garden work. Though it is not hardy in every garden, it is well worth a trial if it were for nothing but the pleasure it gives when flowers are scarce. A.

NEW AND RARE PLANTS.

KALANCHOE FLAMMEA.

I AM very pleased to see this beautiful new plant so highly praised. It is one of the finest things of 1899. There was a most attractive group at Kew last year, and it was also well shown from the same source at the hybrid conference held at Chiswick. True, it had flowered previously at Kew for the first time in 1897, but last year was the first occasion on which its great merits were generally recognised. When exhibited it was generally understood that the entire stock had passed into the hands of Messrs. James Veitch and Sons, and as they are already offering seed, it will doubtless be soon extensively grown. This

Kalanchoe, which is a native of Somaliland, is a near relative of *Crassula* or *Kalosanthes coccinea*, and, like that, is a plant of easy culture. It forms a branching specimen about 18 inches high, of erect growth, and clothed with green spatulate leaves, from 2 inches to 3 inches long, disposed in pairs. The flowers are arranged in a compound umbel nearly a foot across, and have four petals, very much like a *Bouvardia*, about three-quarters of an inch in width, and of a very charming shade of orange-scarlet. Owing to their succulent nature the individual flowers remain bright and fresh for a considerable period, and a large number are borne in each head. T.

CYPRIPEDIUM SIR R. BULLER.

THIS hybrid is said to have been derived from the intercrossing of *C. Smithi* and *C. insignis*. Though somewhat uncertain as regards the parentage, it is, however, remarkable. The dorsal sepal is $3\frac{1}{2}$ inches long and 3 inches broad, the upper portion being white tinted with rose, thickly spotted with deep rosy purple. The basal two-thirds is pale green, densely covered with deep brown spots. The petals are $3\frac{1}{2}$ inches long and 1 inch broad, pale green at the base, becoming suffused with purple on the apical halves. There are numerous large purple-brown blotches as seen in *C. Swinburnei magnificum*. The lip is $2\frac{1}{2}$ inches long, pale brown, shading to green at the base; the lower sepal pale green, lined with a darker shade of green with some brown spotting at the base. It is a most desirable acquisition. From Mr. W. M. Appleton, Weston-super-Mare. First-class certificate, Royal Horticultural Society, January 9.

LELIA ANCEPS VAR. LEEANA.

THIS is one of the oldest of the white section of *L. anceps*. The sepals and petals are each about 2 inches long, pure white, of good form and substance. The lip has the apical lobe faintly tipped with rose in front; the central area white in front of the yellow disc; the side lobes of a rose tint shading to yellow. On the yellow there are numerous rich purple veins extending from the base outwards. A cut raceme of four flowers came from the collection of Sir T. Lawrence, Bart., Burford, Dorset (gardener, Mr. White).—Award of merit, Royal Horticultural Society, January 9.

ZYGOCOLAX LEOPARDINUS (WIGAN'S VARIETY).

THIS is of remarkable colour. It is the result of intercrossing *Zygopetalum Gautieri* and *Colax jugosus*. The sepals and petals are each rather more than 1 inch long, pale green, beautifully marbled and spotted with rich brown; the lip nearly 1 inch broad, reflexed at the base. The front lobe is pale blue, veined with darker blue, the raised portion which forms the side lobes being of a deeper shade of colour, mottled with white at the base. It is a distinct and desirable form from Sir F. Wigan, Bart., Clare Lawn, East Sheen. Award of merit, Royal Horticultural Society, January 9.

ZYGOCOLAX WIGANIANA.

THIS is a pretty hybrid between *Z. Mackayi intermedia* and *C. jugosus*, the flowers being about 2 inches in diameter. The ground colour of the sepals and petals is bright green, thickly covered with light brown spotting, the lip white, lined and blotched with deep violet-purple. From Sir F. Wigan, Bart.—Award of merit, Royal Horticultural Society, January 9.

CHINESE PRIMULA GEN. FRENCH.

THIS is one of the most distinct of the semi-double varieties; the flower is of charming form and intense crimson in colour, a rich velvety and welcome shade, so deep that in a group it is remarkably telling. Shown by Messrs. Sutton and Sons, of Reading, at the last meeting of the Royal Horticultural Society, and given an award of merit.

THE FLOWER GARDEN.

A USEFUL HARDY PALM.

CHAMEROPS EXCELSA.

THE Palm that withstand open-air culture in these isles are few in number, and *Trachycarpus Fortunei*, perhaps better known as *Chamerops excelsa*, is the hardiest of this small decorative group. It is a Chinese and Japanese plant, introduced to this country nearly half a century ago, and a large well-cared-for plant is handsome, few ornamental-leaved plants being more effective on the lawn, as the large fan-shaped leaves

being a valuable preventive against insect pests. During the growing season copious supplies of water should be given, as the plant delights in plenty of moisture at the roots.

THE FOAM FLOWER (*TIARELLA CORDIFOLIA*).

This plant, so suitably named the Foam Flower, is not nearly so often seen as it ought to be, although it was introduced to this country from North America over 150 years ago. The accompanying illustration represents quite a small patch, but when seen in a mass 20 feet square it is a most beautiful sight. It is of the simplest culture, requiring a fairly light soil and a plentiful supply of rotten

the leading classes at such exhibitions, we have a far more authentic and reliable selection than all the prophets and oracles in the Chrysanthemum world can possibly produce.

During the past season it has been curious to note the frequency with which some varieties have been shown at our autumn shows, and the almost total absence of some much-lauded novelties. Taking the winning stands in twenty-four classes at our best exhibitions in the United Kingdom, which seems to me to be a fairly representative test, I find the following results:

Mme. Carnot, Australia, shown 22 times each; Mrs. G. W. Palmer, Phoebus, 20 times each; Mrs. W. Mease, 19; Mrs. C. Harman Payne, M. Chenou de Leche, Viviani Morel, 18 times each; Edith Tabor, Mme. Gustave Henry, 16 times each; Mrs.

THE FOAM FLOWER (*TIARELLA CORDIFOLIA*) IN MR. KINGSMILL'S GARDEN.

are of a pleasing shade of green, and give quite a tropical aspect to the surroundings. Although not particular as regards soil, one composed largely of turfy loam and peat suits it admirably, but particular attention should be paid to drainage, as once the roots travel into sour soil, the leaves soon change from the healthy green to an ugly yellowish brown shade. Position is another point of importance. The plants should be sheltered from biting winds, as the young fronds are susceptible to disfigurement by winds from the east and north. This Palm is admirably adapted for subtropical gardening, also for growing in pots for placing in vestibules, lobbies, &c., as gas has little effect upon it. When grown under cover the leaves should be sponged occasionally with soft soap and water, which greatly increases the general appearance of the plant, as well as

wood, in which it spreads literally like a weed, and although its chief charm is, of course, its flowers, its leaves are lovely all the year round.

Narrow Wood, Middlesex.

A. KINGSMILL.

MOST POPULAR CHRYSANTHEMUMS.

It often happens that a young Chrysanthemum grower, bewildered perhaps by the never-ending lists of varieties that come before him, applies to the Press for advice as to the best twenty-four, thirty-six, and forty-eight varieties for show purposes. There can be no surer test of the value of show Chrysanthemums than the show boards at our leading exhibitions, and if we tabulate the names of the varieties on the winning stands in

J. Lewis, 15; Pride of Exmouth, 14; Charles Davis, Lady Harham, 13 times each; Lady Ridgway, M. Hoste, 12 times each; Pride of Madford, Eva Knowles, 11 times each; Mme. L. Rémy, Mrs. Weeks, Edwin Molyneux, Robert Powell, Mutual Friend, 10 times each; Graphie, G. J. Warren, Mrs. White Popham, Miss Nellie Pickett, 9 times each; J. Bidencope, President Nomin, Le Grand Dragon, 8 times each; Mme. G. Bruant, Secrétaire Fierens, M. Pankoucke, N.C.S. Jubilee, Duke of Wellington, 7 times each. Other varieties in order of merit shown less than seven times each are Oceana, Modesto, Mrs. J. Barks, Simplicity, Soleil d'Octobre, Mme. Ph. Rivore, Souvenir de F. Rosette, Milano, Chatsworth, Lord Ludlow, Australian Gold, and Marie Calvat.

C. HARMAN PAYNE.

TREES AND SHRUBS.

THE SHRUBBERY.

PROBABLY there is no branch of gardening more commonly neglected than the shrubbery, and even professional gardeners often appear to consider it no part of their duty to keep it in order; indeed, when they make an attempt in that direction by clearing out some of the ruder growth they are very likely to find their efforts discouraged and to hear a great outcry raised about the destruction which they have caused. The common idea of a shrubbery seems to be that it should be thickly planted and then left to itself, a few choice plants or flowers being introduced on the extreme margin. The result of this treatment is that in a few years nothing is left but the stronger and commoner shrubs, such as Privet, Laurel, and Aucuba, and these are all crowded together in such a way that they cannot take their natural forms, nor show such beauty as they possess; in consequence, it is very rare to find anyone, even though they may be very fond of flowers and interested in their garden, who takes any heed whatever of their shrubs or looks upon them in any other light than as necessary furniture to shut out the view of a road or outbuildings, or at best as a dark background which will enhance the beauty of a Gladiolus or a Sunflower.

I hope, however, to be able to show that this is not the fault of the shrubs, but of the way they are treated, and that if they are carefully planted, judiciously disposed, and well looked after, they may be made a most interesting feature, showing profusion of flower and blossom in the earlier months and even more brilliant colouring from their foliage in the autumn. Many people will say, "Oh! I have only a small garden; it is no use my attempting shrubs, I have no room"; but I would reply that though I have very often heard this speech I have hardly ever seen any garden, whatever its size, without some trees or shrubs which were either ill-grown, unsuited to their position, or damaging to their neighbours, and which would have greatly benefited from their removal and replacement by others of more merit and distinctive character.

Let us, however, imagine someone deciding either to form a collection of shrubs *de novo*, or clearing out and replanting an old neglected shrubbery, and consider what had better be done. The latter is likely to be the more usual, though not in the end the most satisfactory, proceeding, and may, therefore, be first discussed.

In the first place, if there be any large number of old, big forest trees, such as Elm or Beech, and the owner is not willing to sacrifice them, it is perfectly useless to introduce a lot of fancy plants into their vicinity, as there are not more than about half-a-dozen shrubs of any kind that will do well in such conditions; but supposing that the trees are not very big nor very numerous, and are of such a nature as Birch or Acacia, which are two of those that are least hurtful to the undergrowth, then I would look them carefully over and remove all that I could possibly spare without laying the place too bare, seeing that all the condemned trees were stocked clean out and their roots extirpated. Very often people content themselves with having trees cut down close to the ground to save expense, but this in a garden at any rate is false economy, for it

should be remembered that a tree occupies, generally speaking, as much room under ground as it does above. Though the mere cutting of it down will relieve its neighbours from the disadvantage of shade and drip, it will not render the adjoining ground a fit receptacle for young and tender shrubs, nor in the case of most deciduous trees will the operation kill the roots at all, and consequently an unsightly coppice growth will take place, accompanied often by a quantity of suckers for a considerable circumference. No one without actual experience would believe the distance to which the roots of old trees such as Elms will travel, nor the mischief which they do by exhaustion of the soil. Sooner or later, therefore, the stool will have to be stocked out, and this will be found more laborious and expensive than it would have been with the weight of the tree helping the task of extirpation.

I would never recommend anyone who was attempting to clear out a garden with a view to renovation to take it all in hand at once, both on account of the devastated appearance at first necessarily produced, and because of the loss of accustomed shelter which must be involved. It is far better to work in sections, doing a piece every year, and starting by turning the worst planted part into the best by filling it pretty full with as large an assortment as it can hold of choice trees and shrubs. In two years' time these will have closed up sufficiently to provide a nursery from which to draw for improving other parts of the garden, and the gaps so made can be filled by smaller specimens of plants lacking to your collection. It is desirable to buy your shrubs small in the first instance from the nurseryman, both on the score of expense and because the loss owing to removal from a distance is both less frequent and less important. On the other hand, small and weakly plants are less fitted to live alongside old overgrown stuff than those which are well rooted and five or six years old; therefore the advantage is obvious of starting by filling up the barest and worst section of the garden with a shrubbery that will really form your private nursery, from which you can draw out duplicates and vigorous plants, which, owing to the short distance to their new quarters, can be removed with a large ball of earth and with only a few minutes' exposure of their roots to the air.

It should be borne in mind that a good loamy soil is all important to almost every shrub in its young state, though many of them, if they be given a good start, will, when once well established, fight along very well and push their roots through barren or heavy soil, whereas they would have been quite incapable of such an effort after the first shock of removal. It therefore follows that if disappointment is not to result, you must, unless your soil is exceptionally good, see that your new purchases are hospitably received and treated to the best nourishment you can provide until they have made themselves at home. The clearing out of an old vine border or the top spit of grass-land, where for any reason pasture is being broken up, will provide you with a useful fund for this purpose. Not one penny which is spent on trenching and draining of the ground (assuming it to be properly done), or on care in planting the young shrubs will be found to be thrown away, and in a few years you will be rewarded by your friends saying, "I can't understand why all the things do so well with you, what a splendid soil, climate, &c., you have, if only I were equally well situated, but I find that all my so-and-so's die off," &c., and you will have to bear with becoming resignation the fact that the last thing which it

will occur to your visitors to credit you with is any exceptional supply of brains or pains.

Now, to turn to the consideration of the planting of a new garden with shrubs and trees, here too most of the above remarks will apply, and the task will really be at once easier and more satisfactory. Your main object at first ought to be to secure as rapidly and efficiently as possible for your choicer plants good shelter from the wind. For this purpose *Pinus austriaca*, Larch, Hazel, and even Balsam Poplar should be freely intermingled, as they will serve the purpose well and cheaply, but it must be on the implied understanding that you will harden your heart and ruthlessly clear them out when that purpose has been served and before they have begun to inflict injury instead of benefit.

You will have also to pay regard to the class of plants which are likely to thrive in your soil and climate, and in the first instance, at any rate, confine yourself to these. Thus, if your soil is very heavy, you would do wisely to avoid all delicate conifers, and to remember that even such ordinary trees as Beech and Larch are not likely to give a very good result, whilst, if your soil is light and shallow, to plant Oak would be a waste of money, and though none of your trees will in such a case ever assume enormous proportions, yet among the best will be found those mentioned as unsuitable to clay.

Of course to give a list of all trees and shrubs suited to particular grounds would be quite outside the limits of an article like this, and, feeling that I have already trespassed on the editor's indulgence, I will conclude with a word of warning to beginners not to attempt the growth of half-hardy plants, as in most places in England other than on the seacoast a collection must be a very large one that includes all the beautiful trees and shrubs which can be grown without needing any protection.

VICARY GRASS.

Abraham House, Elstree, Herts.

Hibbertia dentata. In any selection of greenhouse climbers, however small, this should have a place, as it flowers in the depth of winter and continues for some time, and its leaves are handsome also. It is of a slender, twining habit of growth, while the oblong-shaped leaves are deep green in the adult stage, but when young tinged with bronzy-red. The bark of the young shoots is also of the same tint. The flowers are from 1½ inches to 2 inches across and of a bright yellow colour. Their general appearance reminds one of a *Hypericum*. The *Hibbertias* are nearly all natives of Australia. Some form little twiggy bushes, while one species, *H. volubilis*, is a bold-growing climber, with large showy yellow flowers, which are, however, unpleasantly scented. As a garden plant *H. dentata* is far and away the best of them all.

Stokesia cyanea in Devonshire.—On page 480 "E. J." writes that he was not aware that this plant was generally flowered in Devonshire. He is right about South Devon—North Devon gardens I am but little acquainted with—but this is owing to its being so little grown, and not to its failing to produce bloom in the open. During the past five years this plant has flowered well in a flat bed of heavy loam in a very open situation, and was an exceedingly pretty sight during the last week in September, a period at which *Aster grandiflorus*, another late-blooming autumnal plant, had not attained the full measure of its beauty, which generally reaches its zenith about mid-October. Both plants are sufficiently attractive to deserve pot culture in localities where climatic conditions are unfavourable to flower-production. In a damp and semi-shaded position the *Stokesia* not unfrequently perishes in the winter even in South Devon. In mild seasons it flowers through the greater part of October and often into November.—S. W. F.

STOVE AND GREENHOUSE.

CARNATION MME. THERESE FRANCO.

No other Carnation probably has created such a diversity of opinion as to its merits as this variety. To the market grower it may not be so profitable as some others, owing to its successional habit of flowering, as growers for profit like those varieties best which make a display all at once, and which can then be put on one side to make room for others; but the habit which market growers like least of all is the very one which makes such varieties the most valuable for private growers, who have to keep up a constant, if limited, supply from comparatively few plants. Personally, I look on this as quite the best winter-flowering Carnation I have ever grown, and I do not think it is likely to be soon beaten, for in colour, size, and form, combined with a good constitution, it meets the requirements of most growers. Certainly, the colour is not quite so clear as that of Miss Joliffe, but the flowers are superior to those of that once popular variety, and when cut in the young stage there is not much to choose between them, and for those who care for deeper colour the flowers may be allowed to get a few days older before cutting. The question of identity between Mme. Therese Franco and Mrs. Leopold Rothschild has never been definitely settled; but, as far as I can see, and I have grown this year batches under both names and obtained from different sources, they are absolutely the same. The nearest approach to Mme. Therese Franco in colour is Reginald Godfrey, but this lovely variety does not deepen so much with age and is a little paler when opening; but I cannot see that it will ever take the place of the older variety with private growers, as it does not make so much grass or give so many flowers, though those borne by each plant come in practically together, and this may enhance its value for market.

J. C. TALLACK.

a bright orange-red, produced from the axils of the leaves on the tops of the shoots.

Diosca juncata.—A native of Chili, also known under the name of *D. chamaedifolia*, *Baillonia juncata*, *Dipyrena dentata*, *Lippia juncata* and *Vervena juncata*. It is a curious and interesting trailing shrub, producing numerous bunches of small pure white tubular flowers, many bunches of which crown the extremities of every shoot. It is hardy at Kew and flowers in the month of June.

Rhododendron arboreum var. Kingianum. A native of Manipur. A beautiful bright Indian species, named after Sir George King, and bearing fine trusses of tubular flowers of an intense scarlet, with rose-coloured stamens, resembling those of *R. Thomsoni*, but rather smaller.

The first number of the 26th volume of *Revue de l'Horticulture Belge et Etrangere* for the month of January contains portraits of the following two plants (the first of which should not have appeared

by accurate descriptions by a learned Belgian botanist, of the most interesting and uncommon plants bloomed in his rich collection, and bearing the title of *Icones selecta horti Theuensis*. The second part of this work is just on the point of publication.

The January first number of the Paris *Revue Horticole* gives a group or bunch of the well-known Shirley single Poppies, so popular in English gardens. W. E. GUMBLETON.

CREEPER-CLAD COTTAGES.

More of the charm of many a wayside cottage is owing to the way in which it is graced and embowered with climbing plants. Such a bountiful adornment is not only a delightful sight in itself, but in the earlier years of its growth gives to the modest cottage home a sentiment as of a place well loved

A CREEPER-COVERED COTTAGE.

RECENT PLANT PORTRAITS.

THE *Botanical Magazine* for January contains portraits of the following five plants, all bloomed in the Royal Gardens, Kew, and described by Sir Joseph Hooker, the editor:

Coryphantha or Gonopora verticillata. A fine double plate of this noble Orchid, which is a native of Guiana and Venezuela, and produces handsome and most curiously spotted flowers usually in pairs, and somewhat resembling in shape those of a Stanhopea.

Haylockia pusilla. A native of Uruguay, also known under the names of *Sternbergia americana* and *Zephyranthes pusilla*. A most beautiful and interesting little Amryllid, first bloomed by the late Dean Herbert, of Manchester, in his celebrated garden at Spofforth, and named after his gardener. The flowers resemble those of a small *Colehiemum*, and some of them are primrose-yellow and some rosy-white.

Machaonia lasignis, a native of Mexico, is a handsome vacciniaceous greenhouse shrub, with bunches of from three to four tubular flowers of

(till the next number, but is now published, as the plate that should now have appeared is not ready, owing to an accident in the printing):—

Cytisus nigricans.—A graceful pretty Broom, with long upright spikes of yellow flowers, distinctly spotted with reddish-brown on the outer petals.

Entaria myrtifolia. A curious and free-blooming greenhouse shrub belonging to the family of the Podalyric and a native of Western Australia. Its flowers are orange-red in colour and small in size, but most freely produced. This plant was figured in the 31st volume of the *Botanical Magazine* in 1810, but has long ago been dropped out of cultivation, save in botanic gardens, till re-introduced by the Belgian amateur, M. Leon van den Bosch, of Tullefont, who writes a long and interesting article to accompany this plate, on other members of this family and kindred West Australian plants, with which he seems to be most intimately acquainted. This enthusiastic amateur is now also publishing for private circulation only, amongst his friends and botanists generally, a series of beautifully-executed uncoloured plates, accompanied

and well cared for. Then, as the years go by, and the wreathing of beautiful vegetation becomes fuller and stronger, the impression changes; for now it seems as though the climbing plants, with their beauty of leaf and bonny of bloom, had taken upon themselves as a dutious office the guarding and cherishing of the humble dwelling—thus paying back in their time of mature growth their debt of gratitude to those who had kindly and carefully nurtured their youth.

DRACÆNA EECKHAUTEI.

This *Dracæna*, belonging to the same section as *D. rubra*, &c., is undoubtedly the best and most graceful of all the green varieties. It has pretty arching leaves, which often attain a length of 2 feet. The great feature of this plant is that it does not drop its leaves in the way that most of the other varieties do, tall plants retaining their foliage to the bottom. We saw a fine specimen lately at Messrs. J. Veitch and Sons' Nursery, Chelsea.

DOUBLE ROCKETS.

A LETTER FROM IRELAND.

I HAVE seen with interest Mr. Arnott's paper in *THE GARDEN*, December 30, p. 518, on double Rockets, although it contains the somewhat chilling intimation that his "taste does not lie in that direction"! Where does he expect to go to? I solemnly pray that he may be judged with mercy. Why, what June flowers can be placed above (I had almost said along with) them? Not only are they beautiful, but their scent is delicious. To stroll out on a fine June evening about eight or nine o'clock where some large clumps are in full bloom is a joy. The whole air is laden with perfume, and they smell nearly as powerfully in the daytime. Mr. Arnott mentions varieties, and although I know that picking holes in colours is like dancing on eggs—very delicate ground

I must ask him for some clear description of "a double scarlet or crimson" variety! "Double scarlet or crimson"! I can hardly believe my eyes. I thought I knew as much about double Rockets as most people, as I nearly worship them, but anything approaching to such a colour I never saw or heard of.

I at present possess in quantity six varieties: The French white; the Scotch or Eglinton, as it is often called (this kind has, I may say always, a faint trace of lilac at the top of its spike); the true old pure double white; the pale lilac, the most vigorous grower of all; the true old lilac, now nearly extinct (I was searching for it for thirty years, and at last discovered it to my great joy in an old garden in Westmeath); and the lower growing, shorter-spiked purple. This, I recollect, used to be called Parke's Rocket. I wonder whether my old lilac could by any possibility be Mr. Arnott's scarlet! I should be happy to give him a plant in April if he cared to write and ask me for one.

I have had (in a place I lived at thirty years ago) the old pure white and the old lilac 24 inches in spike. Here I have never gone beyond 19 inches. Many people make the mistake of allowing the side shoots to remain on. This gives the plant rather a weedy appearance, and of course takes from the length and majesty of the main spike.

Double Rockets are essentially plants for rich, deep, moist soils. I know that Miss Jekyll finds them difficult to grow on her sandy soil, but she has gone to great trouble with them, and imported strong soil specially for them from a distance. They are plants that cannot be left alone or left long in the same soil. Every third year at least they should be taken up and divided, placed in new soil, with which plenty of well-rotted cow manure and some lime rubbish have been incorporated. They strike very freely from cuttings put down as soon as they begin to push in spring, but they divide so satisfactorily, that now that I have plenty of them I do not go to the trouble of making cuttings. They have an enemy in the shape of a nasty white grub, which attacks them and eats out the blossom-spike when they are about 9 inches or so high. It must be searched for and destroyed. The curling of the leaves infallibly shows its presence.

It would be indeed a pity were such delightful flowers as double Rockets to pass out of existence. We have to deplore the loss to the

world of several favourites which I remember long, long ago. I may mention the double white Hepatica and the late double white Primrose.

Virginia Rectory, Ireland.

DENIS KNOX.

WHITE ROCKETS IN THE SOUTH.

ON page 518, vol. lvi., Mr. S. Arnott writes of the double Rockets, and views with regret the possibility of their loss. Whatever may be the case in Scotland, I do not fancy that their disappearance is imminent in the south-west of England, for, although they are not everybody's flower, they are still to be found in numbers of gardens. In a certain South Devon village many garden plots contain Rockets, a row in a narrow border in front of some almshouses containing, two years ago, some of the most vigorous plants it has ever been my lot to see. Personally, I am extremely partial to the double white Rocket, which I have now grown with success for nearly twenty

M. HENRY DE VILMORIN.

years, and would not willingly miss its delightful perfume on the dewy summer evenings. Its culture certainly involves a little more labour than is requisite in the case of the majority of hardy perennials, since continued robustness can only be maintained by dividing the plants in the autumn (some growers prefer the spring) and replanting in fresh soil. When treated in this manner, and provided with a deep and moderately rich root-run, the plants will attain a height of almost 3 feet, and produce fragrant bloom-spikes a foot in length. If these spikes are cut as soon as they commence to fade and become unsightly, the flowering period is extended for some weeks by the formation of bloom-bearing side shoots. Many years ago I grew the double purple Rocket, but gave it up, as I considered it far inferior to the white variety. At the same time I endeavoured to obtain the double crimson of which I had heard, but was unsuccessful. Now that the taste for old-fashioned flowers is spreading, the double Rocket, an especial favourite in our grandmothers' gardens, should be one of the first plants to benefit from extended culture, since its merits are undeniable. Single Rockets when grown in masses in the wild garden have a simple and pleasing effect.

S. W. F.

M. HENRY DE VILMORIN.

WE this week print a portrait of M. Henry de Vilmorin, which was engraved to accompany the dedication of the last volume of *THE GARDEN*, and some particulars of whose life will be found in the number for December 30, 1899. The engraving was delayed owing to the congestion caused by the Christmas traffic.

WOODLAND AND FOREST.

BIG FIRS.

THE big Oaks and Spanish Chestnuts have often been chronicled, but, so far as I have read, the big Larches, Spruces, and other members of the Pine family are not so well known. The Silver Fir, I believe, ranks first for size among the coniferae in Great Britain, and the largest are on the Duke of Argyle's estate at Rosneath Castle. One day not long since, while walking on the road to Inverary, I inquired of a man working on the roads if there were any fine trees in the neighbourhood, and his reply was: "Man, ye should see 'Adam and Eve.'" These, I learned, were two Silver Firs standing in a wood near the extremity of the peninsula which, near Helensburgh, on the Clyde, is separated from the mainland by the Gareloch. I was not long in getting a skiff and crossing over to the point indicated, where, growing close to the salt water's edge, I found one of the finest Spruce woods I have ever seen. All the trees were huge, running, I should say, to 400 and 500 cubic feet in bulk, and near the middle of the wood I found "Adam" and his partner, each carefully protected by a spiked pading. The tops of both trees had long ago been snapped off by gales some 40 feet or 50 feet up, and from the breaks on each huge limb, containing many cubic feet, had sprung. I was told that each tree contained about 700 cubic feet of timber, and their height would be about 120 feet. The plantation in which they stand is one of the oldest of the kind in this country. Argyle and Dumbarton are noted for their Spruces. On the highway to Luss, and close to Loch Lomond, are extensive woods in which are fine examples of both the Spruces, almost equalling in size those of Rosneath. At Paxton House, near Berwick-on-Tweed, are also some grand old specimens of the Silver Fir, as old, I should think, as those on the Clyde, but not quite so large. The east does not suit this tree so well as the west, and when I saw the Paxton House trees they were evidently in a state of decay.

The Larch ranks next to the Spruce for size. The two well-known trees in the grounds of the Duke of Athole at Dmkeld are popularly supposed to be the first Larches planted in Britain and the largest of their kind. That, however, is not the case. The biggest Larches, of which there are a number, are at Monymusk, in Aberdeenshire, on Sir Arthur Grant's estate, noted for its timber, especially its Scotch Fir, said to be the best in Scotland. I had the opportunity of looking over the woods there last year by the kindness of Sir Arthur Grant, and had the measurements given me of the Larch, one or two of which exceeded the Dmkeld trees in cubic feet, and, if I remember rightly, the latter measured together nearly 700 feet. They are

fine trees in both places. Close by the Dunkeld Larches is one of the largest Douglas Firs in the country also. This tree was planted in 1845, and contains about 100 cubic feet. I have measured it twice within the last fifteen years, guessing the height, and it cannot be much less than I have stated. This tree shows what the Douglas Fir may be expected to do as a timber tree. If a lawn specimen will produce 100 cubic feet in fifty years or less, plantation trees, reckoned at half that in the same time (an ample allowance), should produce a crop of from 15,000 feet to 20,000 feet to the acre and from 7000 feet to 10,000 feet in fifty years. In German forests 17,000 feet is expected in the final yield of Spruce under fair conditions. There are some very big Larches here and there in England and Wales, but none equalling the Scotch trees.

Many grand examples of the Scotch Fir are to be found in Scotland, and there are some fine examples at Monymusk, on the river Don, not far from the Larch trees before mentioned. A great inroad was made in the mature Scotch Fir forests when the Highland railways were made. Sixty thousand pounds' worth was supplied from Athole woods alone from near Dunkeld for sleepers. The Queen's natural Scotch Fir woods near Balmoral are now spared, but there was a time, not so long ago, when trees existed there from which planks 3 feet wide and proportionally long could be cut. The run on big Scotch Fir in England has swept the older trees away, but trees 4 feet in diameter, containing timber every way equal to the best Scotch, have been felled on the Surrey sands. At the present time there still exist on the Beaulieu Abbey estate, in the New Forest, Scotch Firs running from 120 feet to 130 feet in height with clean, model trunks of splendid timber. These trees were planted by John Duke of Monmouth some time in the last century, but they have been grown on a different plan from that practised on the later generations of Scotch Fir there. Plenty of examples are yet to be found, I believe, in Scotland containing from 200 to 300 cubic feet, but such grand trees as were once felled in Glenmore Forest are, I fear, no longer to be found. It is recorded that Scotch Fir once grew there from which planks over 5 feet in width could be cut, a diameter which would mean something like 500 cubic feet in the trunk.

What the dimensions of some of the exotic conifers introduced within the last 200 years may be now we have no good record, but there must be some fine specimens in existence in various parts of the country. I know of no place where such a collection can be seen as that at Murtle Castle, Perthshire. I believe all the conifers likely to grow in this country have been tried there, the different species having been planted as soon as they were introduced, and the extensive grounds, devoted almost entirely to the newer conifers, present the appearance of a forest more than anything else.

The Wellingtonias, Cedars, Douglas Firs, *Pinus mollis*, *P. Lambertiana*, *P. Strobus*, *Abies Albertiana*, *A. firma*, *A. Nordmanniana*, *Arancias*, *Taxodimus*, *Thuja*, &c., are all of large size, showing their comparative merits as growers at least, in a climate that must test their hardiness as far as severe winters are concerned. Mr. Murray Latley, of Murtle, and now head forester on Lord Powerscourt's estates in Ireland, could furnish much interesting information about the Murtle trees. I spent a very pleasant day with him amongst his trees last year, but had not time to take so many notes as I could have wished.

J. SIMPSON.

THE UMBRELLA PINE.

PLANTED in fertile soil and suitably placed, *Sciadopitys verticillata* (Umbrella Pine) is not only distinct, but one of the most delightful of Japanese conifers. In its native country it is said to grow to a height of 100 feet or more, but few plants in these isles are as yet 30 feet high, although it was introduced nearly forty years ago. It is of slow growth, of pyramidal habit, with stout horizontal branches, and long, narrow, deep green leathery leaves borne in whorls at the points of the shoots, which when fully expanded bear some resemblance to an umbrella, hence the popular name, although, botanically considered, the tree is quite distinct from the Pine family. This uncommon conifer thrives best in a compost of fibrous peat, turfy loam and leaf soil. Perfect drainage and a position shielded from east winds should also be secured.

ASTER, OR CALLISTEPHUS SINENSIS.

A FEW weeks ago several notes appeared in THE GARDEN about this new form of an old friend, but we think that none of them gave it the whole-hearted commendation that so good a plant deserves. We have long wanted a free-growing China Aster, whether single or double, and here is exactly the noble plant of handsome habit and abundant bloom that answers the need.

If seed growers would only give some attention to producing forms of plants that are really desired, how greatly it would add to the beauty of our gardens. As a rule, they seem still to hold to the demands that resulted from the prevalent practice of the bedding system, which required that all plants should be dwarf and compact. Much of this influence was destructive to true utility, derogating the plant from its true place and character as a thing of beauty to a lower position as a mere impersonal unit in a space of colouring of some even height. And though bedding is still practised and in its own place quite rightly, it has now given way to the better garden knowledge, which desires that each good plant should preserve its own individual dignity and present itself in the best and handsomest form that is suitable to its nature. And as year by year the eyes of more people are being opened to the delights of good gardening, so they are learning to see for themselves what are the qualities that go to the making of a good plant, and so also they become impatient when a thing that is capable of displaying the highest beauty is driven into a form that is no longer approved, and therefore is no longer wanted.

Many a time we have heard of late of the owners of good places forbidding their gardeners to grow China Asters, on the ground of their being stiff, ugly, and uninteresting. It cannot be denied that, judging by the best standards of taste, they are so. Here is a plant, whose fault already was a certain over-rigidity and stiffness of form, stunted into still greater stiffness.

We do not want a plant to be weak or loose or sprawly any more than we want it to be of the inevitable dwarf and compact shape; but we wish it to be of fair size without being gross, well balanced without being stiff, and handsomely set with good flowers without being crowded. We want the plant to be developed to the *best point of beauty of which it is capable*, but not to be driven beyond that point. Some races of plants can be bred into several kinds of good forms. Nearly all are capable of distortion and of being driven by ill-judged selection into shapes that are undesirable.

It has always been one of the chief aims of THE GARDEN to give encouragement to everything that will promote the beauty of plants as individuals as well as of gardening in broader views. We therefore make an earnest appeal to seed-growers to give us the beautiful plants that we want rather than to continue in pursuit of an unworthy ideal. How gladly we should hail the coming of a race of double China Asters with flowers of the older forms, but still more with those of the later and more free and desirable shapes, such as the Comet class, on large, free bushes such as we have in this fine new or, perhaps more correctly, new-old *Aster sinensis*. We have little hesitation in saying that such developments would without doubt meet with the success that they would deserve, and would not only prove of sound commercial value, but would give to thousands of people who love their gardens a greatly desired form of what might be a much more popular plant.

The dwarfed kinds need not be abandoned. Against their use by cottage folk, whose simple minds are attracted by the very qualities that make them unwelcome to those whose views of gardening are wider, we have nothing to say. The compact forms will always find favour with market growers, for the plant can be cheaply grown and potted up when in flower straight from the open ground, when it is gladly bought by poor town-dwellers for a few pence off barrows in the street.

We want first a good white single flower in all ways like the present purple. The many varieties already to hand show how willingly the plant breaks into varied forms. But we want to retain the handsome bush size and shape, and the strong, wholesome constitution which is shown not only by the length of time the whole plant remains in beauty, but by the long life of the cut blooms. We had three successive pickings, each of which lasted in water for a time that was nearer three weeks than a fortnight.

ON page 501 of last year's GARDEN there is a note by Mr. Jenkins, of Hampton Hill, which speaks disparagingly of the desirability of growing species of plants. He is writing of *Callistephus hortensis*, of which I have at present had no experience, but taking it that it is, as he assumes, "the original kind," it is extremely unlikely that the cultivated forms will "revert exactly to the original if left alone." Very often it is an undoubted fact that the species is much more beautiful and graceful than the plants that are raised by the hybridists from the original, and garden lovers are very pleased when a species is re-introduced, and surely such re-introduction ought to be encouraged as much as possible. To take one solitary instance, I may mention the case of *Chrysanthemum coronarium*, which was originally introduced into this country in 1620—oddly enough, exactly the same period which Mr. Jenkins gives for the introduction of *Callistephus*. In 1882 I saw this *Chrysanthemum* growing in profusion in Algeria, and brought home two small seedlings from which I ultimately got a good supply of seed. From this seed I raised a large patch of the plant, and Mr. Robinson, the late editor of THE GARDEN, was so charmed with the flower that he figured it in his paper, and alluded to me as having re-introduced it. It was greatly admired, and rightly considered much better than any of the many coloured varieties, the work of hybridists during the last 170 years. I had so many applications for seed from gardening friends and correspondents, that I had to have printed labels made for the packets which I sent them. Up till now, that is after seventeen years' trial, the plant comes absolutely true from seed.

A coloured plate of this fine plant was given in THE GARDEN of November 22, 1887.

AN ARTIST'S NOTE-BOOK.

THE HARDY PHYSALIS.

THE merit of the old favourite Winter Cherry (*Physalis Alkekengi*) has been temporarily eclipsed by the glory of its newer big brother *P. Franchetti*. This is certainly a grand thing, larger in every way and just as easy to grow. But now that it has been with us a year or two, many good gardeners see that the older and smaller plant is by no means to be discarded in favour of the new giant. It is one of the many cases in which it is hard to say that as a garden plant the larger is in all ways the better. It seems the wiser plan to keep and grow both kinds. For indoor decora-

tion the old kind is the neater and handier to arrange, and it seems likely that as time goes on the smaller *Cerise en chemise*, as our French friends call it, will quite hold its own in general favour. It appears doubtful whether there is any botanical distinction between these two plants. *P. Franchetti* came a few years ago from Japan, and is a very handsome form, bolder and larger altogether than *P. Alkekengi*. They are both represented in the accompanying illustration. Both like a warm place in rich loamy soil.

PHYSALIS ALKEKENGI AND *P. FRANCHETTI* (LARGER KIND).
(From a Drawing by Aynes Cook.)

Though the larger *P. Franchetti* is far less graceful than the more familiar *P. Alkekengi*, it is showier, especially when grouped in the garden. We saw late last autumn a noble bed of it, and at a distance wondered what plant produced such a rich orange-searlet colouring. In this way, therefore, to produce bold effect, *P. Franchetti* is more valuable than the older species.

The *Physalises* are not used so much as they deserve to be for room decoration during the winter months. The wiry stems upon which hang the Chinese lantern-like calyces remain for many months as fresh almost as when first used, and their brightness is a distinct improvement upon many of the dowdy things used as "everlastings" in the winter. Associated with the

silvery *Honesty*, the *Physalis* is distinctly pleasing, but there are other ways in which it may be employed.

HELIOPHILA SCANDENS.

THE plant illustrated is an acquisition of no slight importance: it is a climber of free growth, with a profusion of white Jasmine-like flowers in the winter months. We recently noticed it in beauty in the succulent house at Kew, the twining stems falling down gracefully and creating an unusual effect. Where *Clematis indivisa* succeeds, *Heliofila scandens* is happy also.

IRIS STYLOSA.

SUCH rare blossoms as brighten this dull season are all the more precious owing to their infrequency. The touch of frost that we have already experienced has acted prejudicially in destroying and retarding bloom in more northern localities, and also in such southern and south-western gardens as lie in exposed situations. In sheltered nooks, however, the lovely Algerian Iris (*I. stylosa* or *unguicularis*) and its white variety are in flower, and, where some slight protection is afforded, remain uninjured except by severe frosts, a mulching of some light material round the clump and an inverted hamper placed over the plant at night generally sufficing to preserve the unexpanded buds—in which condition they should be cut for indoor decoration—from injury.

BEGONIAS AFTER FLOWERING.

As the plants of that popular winter-flowering Begonia, *Gloire de Lorraine*, go out of flower they should be taken from the flowering house, and after having shortened back the growth so that they may be stored closely together, placed in a pit where they can enjoy an intermediate temperature, a light position and an atmosphere in which there is a moderate amount of moisture. Very little water should be given to the roots during the next few weeks, as the best cuttings are given by plants which have been allowed to rest for a time, and nothing is gained by hurrying their production. The best and the only cuttings that should be used, except, perhaps, where stock plants are limited in number, are those thrown up in the form of sucker growths from the base of the plants; these grow away freely from the first and do not give half the trouble that stem cuttings give in picking off flower buds while the plants are small; they also make growth of the best character for basket plants, and it is in baskets that this plant is seen at its best. Fumigate the pit frequently to destroy any of the little yellow thrips which are so partial to Begonias, and do not allow any other plants which these insects infest to be brought into the house, for they are difficult pests to destroy, and do more harm than any other insect pests to plants which they attack. It is rather late to advise selection of plants for propagating as the flowers will be getting over, but the best types certainly should be picked out, as the stock is decidedly mixed and contains forms poor by comparison with others.

CARNATIONS.

Winter-flowering Carnations must be struck early to get good plants by the autumn and probably most growers will have already secured an early batch, but successional plants are very useful when room can be found for them, and the present is an excellent time for putting in the cuttings, as most varieties will now be producing plenty of the side growths which are the most satisfactory for the purpose. I like to pull out the shoots in the form of "pipings," and do not use a knife. Use sand freely in the cutting pots, make each piping firm, water well in, and after having allowed the pots to drain, plunge them in a fairly brisk hot-bed. The tops should be kept cool and the soil warm, then they root well without becoming drawn.

Shipley Hall Gardens, Derby.

HELIOTHELA SCANDENS.
(From a drawing by H. G. Moon.)

INDOOR GARDEN.

EUPHORBIA JAC-
QUINLEFLORA.

FEW plants flowering through the mid-winter season and the early year are more generally prized than the subject of this note. The brilliancy of its floral bracts borne on gracefully arching racemes renders the plant one of the most valuable for the season indicated above. The chief enemy of the plant is water given usually largely in excess of the actual needs of the plant. As one of the rather numerous company of the Spurge or Milk-wort family, it is obvious that much moisture is at once detrimental to it. Equally dangerous, too, is a temperature that wavers frequently between two extremes. It is due to the way the plant suffers from the latter that its use as a pot plant is much curtailed, unless, indeed, as the outcome of experience, a gradual diminution is resorted to. The plant suffers most when taken from the usually warm and moist conditions of the stove, and is better able to endure vicissitudes of temperature when grown in warm though dry surroundings. Small plants in 5-inch pots or thereabouts are those usually seen, and are generally propagated in spring from cuttings, propagation being necessary each year, as the older plants resent interference of the roots. Being generally a feeble, or perhaps more correctly a sparse-rooting subject, dryness of the soil is at all times the safest from the cultural standpoint. Waterlogged plants are rarely long-lived, and for this reason water must be always given with exceeding care. Much may be done to avoid over-watering by a free, perfect drainage and

an admixture of soils that may be regarded proof against a waterlogged state. Such a soil may be made up as follows: Rather clayey loam three parts, the fourth part consisting of well-pounded brick rubble or burnt clay, silver sand, leaf soil, charcoal, and old cow manure in equal portions. Many use peat for this subject, but frequently the water-holding capacity of many peat soils is almost that of a sponge, and for this reason peat is not recommended unconditionally. Peat of the right stamp is not objectionable, but it is certainly not an essential detail in the culture of this plant. Indeed, the most vigorous plants I have ever seen were planted out for stock purposes in strong brick earth warmed by an old brick flue. Some of the success of these plants may have been due to the warm and dry condition of the soil, water being very rarely given owing to the free root-run obtainable. Such conditions are not readily imitated with the present system of hot-water heating. At the same time the experience suffices to show the value of dry and warm soil for this plant. The plants referred to were, however, not the best for producing cuttings, as the growth was too vigorous, and stopping of the shoots had to be resorted to, this forcing the axillary buds into

growth. These latter secured when 4 inches long made excellent material for propagation, and were always taken off with a heel attached. With such as these few failures occur. As soon as detached from the parent plant the cuttings may be plunged into dry sand to stop the exudation of the sap. A sharp, brisk bottom-heat is absolutely necessary to root the cuttings successfully, and if covered with a bell-glass all the better. Always insert the cuttings with the heel intact as taken from the plant. Pots nearly half-filled with drainage and the other half clean sand are more serviceable than soil, retaining less water and more generally ready to hand. But whether soil or sand is used it should be quite up to the temperature of the house, or a chill may be given. Such cuttings root in three weeks or a month on a bottom-heat of 85, and when slightly hardened off may be potted at once in the mixture already given. After-culture is a matter of choice. In all cases where the finest racemes are most appreciated it is a good plan to grow four to six plants in a 6-inch pot, selecting at the start plants of uniform strength. These may be grown without stopping at all, and especially well suited for grouping among Palms or in numerous other ways that readily suggest themselves at the moment. Cuttings of these things may be rooted over a long season, and even such as are rooted in May and June are of considerable value for many purposes for which taller plants are not suited. E. J.

The Date Plum.—From a friend in the south of France come the handsome fruits of *Diospyros Kaki*, now largely grown on the Riviera as a dessert fruit. In colour and general appearance

THE ALGERIAN IRIS.
(From a drawing by H. G. Moon.)

they are much like smooth Tomatoes of a good size, as they are often 10 inches in diameter. When ready to eat they are soft and look half-transparent like a ripe Tomato. The pulp, though not very distinctly flavoured, is sweet and pleasant, and the liking for it increases with better acquaintance. It is hardly in warm places against walls in quite the south of England. Its near relative, *D. virginiana*, is the Persimmon of the United States.

GARDENING OF THE WEEK.

ORCHIDS.

ONE of the most interesting and beautiful sections of cool-house Orchids comprises those of the tall-growing Oncidiums to which such kinds as *O. macranthum*, *O. loxense*, *O. serratum*, *O. superbiens*, &c., belong. These are useful in summer, especially when required for exhibition. They are easily cultivated if a suitable position to meet their requirements be found, but unless grown under suitable conditions they are very difficult to manage. I find that the coolest end of the Odontoglossum house is the best place, where there is at all seasons of the year a great amount of moisture about the roots. Shade also, especially from overhanging trees, often proves beneficial during summer. The plants have in many instances commenced to produce their flower-spikes, and are also freely making new roots. This is a good time, therefore, to examine the plants for any potting or top-dressing. If the roots are allowed to become vigorous, it is a difficult matter to deal with the plants without injuring the points of the tender roots. When the compost has become sour and the plant too large for the pot, remove the potting compost first, and then carefully extract the roots, avoiding as far as possible any injury during the operation. After removing all decayed material and cutting away any dead matter, again place them into clean, well-drained pots, which should be sufficiently large to contain the plants comfortably. After the drainage has been brought up to within about 2 inches of the rim of the pot, the remaining space may be filled up with a potting compost composed of equal proportions of chopped living Sphagnum Moss and fibrous peat, pressing moderately firm and mounding towards the centre, so that the new roots can get hold of the new compost, and are thus enabled to re-establish themselves in their new surroundings. As the spikes of these species advance and the flower-buds begin to form, it is desirable that the spikes, which have previously been allowed to roam at will, should be tied securely to three or four neatly painted sticks placed at intervals into the potting compost around the edge of the pot. If this be done before the flowers are too far advanced, they will expand in their proper position.

TREATMENT OF IMPORTED ORCHIDS.

Of these, deciduous *Dendrobiums* are frequently very numerous. One of the first generally to arrive is *D. Wardianum*. The plants may be potted up in pans or placed in baskets as soon as received. The receptacles should just contain the plants comfortably, giving ample and clean drainage. Too much material about the base must be avoided, only sufficient being used to properly secure the plants in the pots. Fix the straggling bulbs securely to suspended wires. Too much heat should not be given at first, and let water be sparingly applied until the growths get well away from the base and new roots are being emitted. While in the cooler division ready for transferring to the stove, let the plants be perfectly dry at the roots, and the atmospheric moisture in the house should be sufficient for their requirements. Other species needing similar conditions to the above are the lovely violet-scented *D. aureum* (*heterocarpanum*) and the white and purple-tipped *D. Devonianum*. The handsome *D. Falconeri* is also freely imported, this species succeeding under cooler conditions, such as a Mexican house, where there is a free circulation of air and plenty of light. They do better in the intermediate house than when cultivated under the same conditions as the deciduous *Dendrobiums*.

H. J. CHAMMAN.

INDOOR PLANTS.

HARD-WOODED PLANTS.

GREENHOUSE hard-wooded plants are somewhat difficult to manage at this time of the year, as on the one hand one has to prevent sharp cutting draughts, and, on the other, stuffiness of atmo-

sphere. Both are bad, and the latter is productive of mildew among the *Ericas*, *Genistas*, *Boronias*, and many others of the section. The preventive is a circulation of air at all times with only just sufficient fire-heat to maintain a minimum temperature of 40°, and the cure is to dust the plants over now and then with the sulphur-duster, which should be applied directly there is the least sign of mildew spots or leaf-shedding. Great care with the water-pot is necessary, for it is easy to make mistakes, especially when the plants are growing on open stages, as the bottoms of the balls of soil are apt to get too dry, while the upper portion is quite wet enough. If the plants are standing on ashes or shingle by far the better practice they will be more easy to manage as regards watering, for the lower roots are able to gain moisture by absorption, and one can better judge of their condition and needs. The atmosphere of the house should be cool and dry, and no water should be allowed to spill or drip, especially among the plants with small leaves and feathery habit.

POINSETTIAS.

As these plants lose their bracts they should be removed to an intermediate temperature and allowed to dry off gradually. If room is scarce, they may be laid on their sides under the stages of any house where the temperature does not fall below 50°, and there remain until they are wanted to make growth again for the supply of cuttings. *Euphorbia jacquiniiflora*, too, may be dried off, but not quite to the same extent or in so low a temperature, as the more slender stems of this plant are liable to die back if subjected to any great changes.

SOWING SEEDS.

For the majority of plants it is full early to think about sowing seeds, but some things, such as hybrid *Streptocarpus*, *Saintpaulia*, tuberous *Begonias*, and others which flower as annuals, if allowed plenty of time to grow, can hardly be sown too soon if space and other conveniences can be given them. All the above-mentioned have very fine seeds, which must be sown on the surface in pots carefully prepared by being well drained to within 2 inches of the rims and filled up with a nice sandy mixture of soil, of which well-decayed and very fine leaf-mould forms the greater part. The soil should be quite level and well watered before sowing the seed. Place the pots in heat, half plunging them in the hotbed material, cover with glass, and shade always during the day. The *Streptocarpus* are especially impatient of sunlight, and will brook no neglect in the matter of shading at any time.

KITCHEN GARDEN.

EARLY PEAS.

FEW vegetables are more appreciated than early Peas, and there are several modes of culture open to the cultivator. The best results are usually obtained from pot plant sown at this date under glass, the seedlings being planted out in suitable weather early in the spring. Care should be taken with pot plants raised under glass not to employ too much heat at first, as this results in weak plants and a poor crop. It is far better to give the plants a little more time, and by so doing secure a strong growth. My previous remarks, of course, apply to plants to be fruited in the open ground, as if the plants are fruited under glass, more warmth may be given at the start. Peas may be forced in various ways. I prefer the seed sown in the fruiting pots if grown in pots from start to finish, three to five plants being put into 7-inch or 8-inch pots. If the plants are to be grown in frames, we sow in 5-inch pots and plant out when large enough. To save time the seed may be sown in rows in the first instance, but frequently the frames or pits needed are in use till the last moment, and there is a great saving of time by starting the seed as advised.

For pot or frame culture I do not know of better varieties than *May Queen*, *Chelsea Gem*, and *Daisy*; the last named, though not so early as the others, is so good as regards size, quality and crop, it cannot be omitted. But as regards forcing varieties there is no lack of excellent kinds, as the new introductions of late have been a great advance on the old white round varieties.

Use a good-sized pot, not less than 5-inch, as this gives more root space, and put six to nine seeds in a pot. If these be planted out during the early part of March, they will give pods the end of May. With dwarf kinds, such as *Chelsea Gem*, *Harbinger* and *Early Morn*, I have, to gain time, sown in 3-inch pots placed in heat till the seeds were well through the soil, and then placed them in cold frames till planting time. Treated thus the plants may be sown much later, and if the land is heavy and cold this may be a gain. It is important to have the land in good condition for planting, and as this vegetable, given pot culture at the start, makes its growth in the open in so short a time, a rich root-run is necessary. In heavy cold soils it will be a great advantage if drains are added and the natural soil lightened. The labour thus spent will not be lost, as after the Pea crop is taken the land will be in good condition for the crop which is to follow, such as salads or other shallow-rooting vegetables. The land should also be got ready for the first sowing in the open, the soil being trenched or turned up roughly in ridges in order to become pulverised by the weather, and in better condition for sowing early next month. It is also well to select the sites for the summer crops, as more time can now be given to the manuring and preparation needed.

TURNIPS.

These are invaluable in April and early May, as at that season the old stored roots are growing out badly and become flavorless. Turnips are not grown in frames as much as they deserve, and few vegetables can be grown more readily, the chief points in their culture being ample ventilation, light, and moisture. Bottom-heat is not a necessity, providing the top temperature is genial at the start to effect germination quickly. I would advise a temperature of 60° at this period, with plenty of ventilation in mild weather as growth increases. The soil should be fairly rich, and of a depth of 6 inches to 8 inches for the long-rooting kinds. For frame culture I find *White Gem* and *Sutton's Forcing* both excellent, as they do not age so quickly as the shallow rooters. For quick growth the *Extra Early Milan* is one of the best, and is also an excellent forcer. Whatever kind is grown, avoid thick sowing, as, unless the plants have room to develop, they run to seed before swelling their roots. If bottom-heat is given, avoid over-heating or dryness at the roots, and if manure is the heating agency it is well before making up the hotbed to get rid of the rank steam, and if procurable to mix some leaves with the manure to make the heat more lasting and less violent.

G. WYTHES.

Syon Gardens, Brentford.

NEW FERNS.

DAVALLIA ILLUSTRIS, a very attractive Hare's-foot Fern, with gracefully arching fronds about a yard long, was the only Fern to which a first-class certificate was awarded last year, and is likely to prove of considerable value for decoration. *Davallia intermedia* is described by Messrs. Veitch as a supposed hybrid between *D. Mooreana* and *D. decora*, and its general appearance would suggest that such was the case. The typical form of *Poly-podium irioides lobatum* has stiff, erect, undivided fronds; it is a plant of wide geographical distribution in a native state, and is a good garden Fern. From this the variety *lobatum* differs in the tips of the fronds breaking up into lobes, some of the fronds having ten to twelve segments at the apex. *Adiantum Burnii* was shown well last year. The slender partially drooping fronds are from 2 feet to 3 feet long, and suggest a certain amount of relationship to *A. amabile*. As a basket Fern it is likely to be of considerable merit.

February Chrysanthemums.

Your correspondent "C. N." calls *Julie Lagravere* and the *Anemone-pompon Marie Stuart* two indispensable Chrysanthemums, but I consider *Maud Dean* better than either in colour and habit, and it is especially suitable for this time of year on account of its brightness and lasting properties. I shall be able to cut flowers of *Maud Dean* until the end of February, if not later. M. JONES, *Undermount Gardens, Banchurch*.

RIVIERA GARDENING.

WE have been reminded of winter lately by one or two chill and cloudy days, and a sudden drop in the temperature at night has brought a white frost in the low-lying grounds, where damp fingers utter cold rain. It is curious to see how northern plants have enjoyed a change, for Wallflowers and Stocks, that seemed at a stand-still, have grown more in a week than in the previous month of fine, hot weather, and bulbs that refused to stir are now showing signs of renewed vigour.

It is at first decidedly perplexing to find one's ideas must be entirely reversed. Iris *stylosa*, for example, is far finer in a shady and cool position than in the open, and Iris *reticulata*, which my French gardener insisted in planting in strong clay soil and in the wettest position he could find, has entirely justified his insistence, for those he has planted are strong and vigorous, ready to flower in a few days, while those I put in a shady dry part are hardly stirring and look droughted and unhappy. No doubt in its native Algeria it grows near watercourses that are dry in the summer.

Tulipa *saxatilis* has flower-buds as big as a large pea, while *T. Kaufmanniana* and *T. Greigi*, planted at the same time, are not yet above ground. Evidently *T. saxatilis* must enjoy warmth much more than other Tulips, and would force easily when fairly strong.

To-day I have been planting a shady walk which will be pleached when the trees are sufficiently grown, as I cannot allow them to grow high in that position. I have chosen for that purpose the Indus Tree and the well-known *Acacia dealbata*, as both these trees flower all the better for being cut well in after flowering. In old days, before the railroad was made and modern French gardening, with its Palms and *palmas*, did not exist, there were many such shady alleys in Nice gardens which in April were a real delight to those who love to look up to the sky through a maze of tender rose-purple colour. *Acacia dealbata* was then practically unknown, and for many years was confined to granitic and sandy soils, such as are found at Cannes and St. Raphael, because it will not grow on a calcareous or clayey soil. Now-a-days, thanks to the gardener's art, it grows and flourishes anywhere when grafted on the hardy *A. floribunda* that is at home on all soils and situations. English gardeners who wish to grow this very attractive tree should certainly ask for grafted plants, as then there is no need to bother about soil. Moreover, it flowers more freely in a young state, which is not without its advantage.

These two trees will not flower exactly at the same season, but between them there will be abundance of flower from early February till the month of May, so that with climbing Roses and various climbers to help, the display will be continuous all the winter.

The demand for flowers at Christmas-time is, of course, very great on the Riviera, and the much colder and less bright weather has prevented any but the hardier flowers from opening quickly. The paper-white Narcissus, so largely grown in spite of its disagreeable smell, is at last being supplemented by an equally early yellow *Tazetta* Narcissus which is so closely like the well-known *Soleil d'Or*, that I daresay it is generally called by that name in England. It is, however, so much earlier, that when in the beginning of December the first blooms of the yellow Narcissus were open in my wild garden, where it grows naturally and has never been destroyed, the tips of the green leaves of the true *Soleil d'Or* were hardly showing above the ground. The heads of the

flowers are larger and slightly paler in colour than *Soleil d'Or*, which should also distinguish it.

Caroline Testout is a Rose of decided promise for winter blooming on this coast. Its clear pink colour, stiff stalk, freedom of bloom and indifference to cold weather are quite remarkable, putting it on a par with the old *Safrano* in that respect, while being a far finer Rose and of better lasting power. So far I have not seen any blooms of Mrs. W. J. Grant or Mme. Jules Grolez, varieties said to be of such great promise, which apparently has not been fulfilled.

E. H. WOODALL.

SOME GOOD HOLLIES.

A NOTE FROM GLASNEVIN.

THIS has been in Ireland a very good year for Holly berries, and one cannot but notice how much more suitable for decorative work some varieties are than others. This is notably the case with the large-leaved, almost spineless varieties. The berries of these are also larger and different in colour from those of the small-leaved spiny kinds. Amongst the best may be named *camelliaefolia*, *Marnocki*, *platyphylla* and *Lawsoni*. There is here a very distinct variety with orange-coloured berries which is quite different from the ordinary yellow-berryed form, and very ornamental.

F. W. MOORE.

BORDERS OF FLOWERS IN THE FAIRHILLS GARDENS, PARLHAM.

A GARDEN OF FLOWERS.

THE accompanying illustration needs few words of description. It displays borders of flowers, with at one end a pergola, over which may be trained a host of climbing plants, Rose, Clematis, Wistaria, Honey-suckle, Vine, and other things precious for their graceful growth and abundance of sweet-smelling flowers. During the winter is the season to make such beautiful borders as here depicted.

[With this note Mr. Moore sends us some well-berryed twigs of some of these good Hollies, pleasant to see in a year when in most parts of England Holly berries are scarce. Amongst them the most noticeable are the golden-variegated *Lawsoni*, with very broad flat leaves, *platyphylla*, with leaves of rather small size, perfectly flat and even-edged, and the one with orange-coloured berries, of a tint quite unusual in the fruit of the Holly. Etc.]

THE FLORENTINE IRIS.

AMONG the many garden varieties of what are broadly classed as the flag-leaved Irises, none is more welcome than the grey-white Iris of Florence. It is one of the easiest to grow, and is quite the most generous in abundance of bloom. With the exception of the common blue, it is also the earliest. Coming as it does with the Oriental Poppies in the month of May, it seems to be the herald of the large flowers of early summer. This noble Iris is beautiful in many ways; in the flower border, among dark-leaved shrubs, or in close association with masonry. But its dignity and nobility of character are best seen when, as shown in the illustration, it is grown in a bold, simple group, away from other flowering plants, on some quiet space of lawn, where large neighbouring trees give wide breadth of reposeful shade. In such a place and against such a background, the flower's noble shape and tenderness of petal-structure may be seen and enjoyed to the full.

GROUP OF THE FLORENTINE IRIS.

Like everything else, this excellent way of displaying the beauty of one good thing at a time should not be overdone or made into a sort of rule throughout any one garden. It would result in a monotony of treatment that would not be desirable. But when a garden has shrubs in reasonable variety and flowering plants in well-planned mixtures, a few fine things isolated in such places as not only show them handsomely, but are also well graced by their presence, are much to be desired. Moreover, when the mind and eye are occupied by the consideration of the one group only, its whole effect and its beauty in detail are presented in circumstances that are undoubtedly the most favourable for the enjoyment of both.

PRIMULA FLORIBUNDA.

SPRING, summer, autumn, and winter seem to be all alike to this pretty little Indian Primrose, which commences to flower as soon as the plants are sufficiently strong, and continues till quite exhausted. It is now about fifteen years since this species was recognised as a very useful plant, and it has been steadily gaining in popularity ever since. It is essentially a greenhouse plant, but its cultural requirements are not at all exacting. A distinct variety of this Primula was exhibited last year under the name of Isabella, in which the flowers are somewhat larger than in the type and of a pale yellow tint.

KITCHEN GARDEN.

DEEP CULTIVATION AND ITS BENEFITS.

THE value of deep trenching for the production of high-class vegetables is now generally understood, and if proof be wanted to bear out this, I would ask my readers to remember the last two dry summers and compare crops which had been treated in the ordinary way with those grown on thoroughly well-trenched ground. The results will, I am sure, convince even the most sceptical. By following out the trenching system thoroughly, the most unfavourable land may be brought into such a state that it will produce almost any kind of vegetable of the best quality.

bringing the bottom to the top, which was almost pure sand and probably had never seen daylight.

I was careful to work in plenty of manure, garden refuse, and indeed anything in the way of rubbish which came to hand. This is by far the neatest, easiest, and best way of getting rid of garden rubbish that I know, besides improving one's garden.

I well remember the remarks passed by older heads than mine: "Ah, young man, you are making a great mistake here." But, if I may say so, I not only proved to myself, by results, but to them also, that I was not very far wrong.

Now, one more instance to bear out what I say. When I took charge of these gardens, nearly 16 years ago, I found the soil here quite different to what I had been accustomed to, viz., a stiff London clay, and anyone acquainted with this kind of soil will, I think, agree that it is one of the poorest to work; and to illustrate more fully what I am trying to convey to those that do not agree with me, my predecessor had established a kitchen garden, two or three miles from here, on the estate, which was a light sandy soil, stating that it was quite impossible to grow early and many kinds of vegetables here. I quietly considered it over, and soon came to the conclusion that I would have a very good try to grow our vegetables at home. I lost no time in following out what I believed to be the right course, trenching 3 feet deep and bringing the clay to the top.

If ever I wavered it was then. The old hands with one consent exclaimed, "I am sure you are making a mistake; we shall not be able to grow anything at all." "Never mind," I said, "go ahead; you haven't had much here lately, and if we are to have less I am responsible." One piece of land in particular, which had been a garden for at least 50 or 60 years, I took in hand, and found a dark worn-out soil about a foot deep underneath a pure yellow clay. This I treated in exactly the same way during 1892, repeating the operation each year. The result is 3 feet of good workable soil, which will now bring to perfection any crop one cares to grow.

EDWIN BECKETT.

Abdenham House Gardens, Elstree, Herts.

EARLY CARROTS.

NOR everyone having a garden can afford to devote a frame in the late winter to the growth of young Carrots; frames are so often needed for other things just then. But a capital makeshift for the benefit of the Carrots can be found in some stout strips of wood, if but 1 inch thick and 3 inches deep, stood on a warm border to fit any ordinary frame-light, and kept upright by the aid of small pegs or stakes driven into the soil beside the strips. If a frame-light not otherwise in use can be utilised for this purpose, so much the better; if none such be at liberty, then the temporary frame may be larger or smaller in area. When made, the soil, having been previously well dug and manured, may be sown with seed of either the Early Gem, Short Horn or the Early Nantes thinly, in shallow drills 6 inches apart. After being watered, the bed should be covered up, some strips of wood being laid across the frame, on these placing two or three mats. There the covering may remain until the seed has germinated, when the bed must be uncovered in the day, but may be covered up again during the night. By the time the plants have become 3 inches in height covering may be dispensed with. When the tops are 6 inches high there should then have been formed to the plants small roots about the dimensions round of a man's little finger. These may be pulled, trimmed, and cooked whole, and are most delicious. Such a sowing may be made at once; and if the first be of the Early Gem, a second one close by may be made of the Early Nantes in rows 6 inches apart with or without a frame. That sowing can be made at the end of February. A final spring sowing of the Intermediate on a larger scale in the open garden should be made early in April, and a summer sowing of the Nantes again in July to form the delicious young Carrots to pull during the winter from the open ground.

A. D.

GLOBE ARTICHOKE.

This vegetable deserves to be cultivated more generally than it is. Far too often it is grown in some out-of-the-way corner, and more often than not inferior kinds take the place of the best varieties. As far as I know, only two are worth attention, the best being the large Green Globe, a variety rounded at the points and almost free from prickles, and a good form of the Brown Globe. This is hardier than the first named, but not so good either for exhibition or the table.

To have these in the best possible condition, liberal treatment should be afforded them, and the old stools should not be allowed to remain in the ground for more than three years. Choose a site which is quite open. This should be heavily manured and deeply trenched during the autumn or winter, and on stiff, heavy land quantities of cinder ashes, road-scrappings, and old mortar rubbish should be worked in. By the end of March or the beginning of April the ground should be forked over, and in genial weather the planting should be performed. Procure suckers from a reliable source, which should be planted singly, allowing a distance of 3 feet from plant to plant, and 4 feet between the rows. Make firm, and earth up with finely-sifted cinder ashes. I have proved the Globe Artichoke to be very partial to these, and I know of nothing so distasteful to slugs. Mutch the whole of the surface with long stable manure and water abundantly in dry weather. As before mentioned, the best variety is somewhat tender, and in early autumn each year a few suckers should be potted up, wintered in a cold frame, and planted in spring. This will ensure the keeping up of a good supply.

The old stools should be protected during severe frosts with long litter or bracken, which should, however, be removed during open weather, or as much harm will accrue as if the plants were left unprotected. Where suckers can be obtained they are always to be preferred to seedlings, as these cannot be depended upon, and worthless kinds are only too often the result of using them.

E. BECKETT.

FORCED ASPARAGUS.

This is one of the best vegetables at this season and readily forced, but is somewhat costly, as one forcing destroys the growth of three or more seasons. To get a regular supply it is well to place roots under glass every three weeks. Many growers lift an old bed and force every year, sowing or planting another in the spring to make up for the loss of plants. One bed will not go far if regular supplies are needed. I prefer to force roots three years old, as these give splendid results, but all have not space to grow their own roots. I would in all cases advise slow forcing, as if too much heat is used the growth is much weaker. I use leaves and manure for early batches, and the top portion of the pit does not exceed 60°. By using leaves the heat is slower and retains moisture. From this date bottom-heat is not necessary, as roots placed on the floor of a warm house, though longer coming in, give strong "grass" if near the light. No matter how forced, to maintain regular supplies there must be no lack of moisture. This given in a tepid state promotes growth. Now is a good time to force permanent beds, which may be done with any heating materials at command. I use leaves largely, but in gardens where flues or hot-water pipes can be utilised there is less trouble.

G. WYTHES.

AN AUSTRALIAN SUNDEW (DROSERA BURKEANA).

ALTHOUGH of world-wide distribution, the Sundews, of which over a hundred have been described, are fairly uniform in character, and the three which inhabit the swamps and marshes of this country resemble very closely the majority of them. Several are included amongst the plants grown by lovers of the

curious, and some are sufficiently beautiful to rank with the choicest of pot plants. Unfortunately, these latter are not yet in cultivation, although one of them, viz., *D. cistiflora*, the most beautiful of all Sundews, was introduced from South Africa, where it is a native, by Miss North in 1889, and flowered the following year at Kew, but died soon afterwards. This has a stem from 4 inches to 9 inches long, clothed with linear gland-covered leaves, and bearing a single flower 2 inches across, resembling both in consistency and colour one of our wild Poppies. Another Cape species, *D. grandiflora*, has equally large flowers of a bright rose colour.

D. Burkeana is a native of Natal, and resembles our native *D. intermedia*, but is larger and its flowers are pink. It is not unlike *D. spatulata*, an Australian species which is frequently to be met with in botanical collections. Other species in cultivation are *D. capensis*, *D. binata* (*dichotoma*), and *D. auriculata*. This last is a slender climbing species with a pea-like tuber, which enables it to support the drought of the sandy wastes of Australia where it is a native. Most of these plants can be multiplied by means of bits of the fleshy roots planted in sand in a warm house. The best position for *Droseras* is a sunny corner in a greenhouse, and they should be planted in pans of chopped sphagnum and peat, which should be well watered daily all through the summer. *Roridula dentata* is a shrubby Sundew, which has been introduced and grown into a bush nearly 2 feet high. In some parts of South Africa, where this plant is a native, the bushes are hung in the houses to serve as fly-catchers.

Kew.

W. WATSON.

sight of the wax-like flowers of *Erica carnea alba*, and one has bent over it with keen delight. It looks too pretty and delicate to be exposed to the inclemencies of the time, yet it suffers not from the weather, and will for long give us the pleasure of a sight of these exquisite tiny little bells, which look like little pearls strung on the slender green branches. Growing in favour though *Erica carnea* is, it is yet needful that it should again and again be brought under the notice of those who take pleasure in their gardens in order to draw from them the fullest enjoyment they can derive from the hardy flowers they contain. It is cheering to see this little Heath in many more gardens now than was at one time the case. It is not difficult to grow in the border or rock garden. In beds, either as an edging or by itself, it is delightful also. So far as one's observation goes, it appears to have less objection to limestone than have some of the Heaths. No one who has ever grown *Erica carnea* will willingly be without its beauties in the dull season of the year.

S. ARNOTT.

Caresthorn, by Dumfries, N.B.

GALAX APHYLLA.

NORMING in the garden just now is much prettier than the leaves of this neat North American plant. They are heart-shaped and prettily toothed at the edges, of thin but firm texture, and boldly carried on strong, but slender wire-like stalks from 4 inches to 9 inches high, and sometimes higher still when well-established clumps are growing in the moist peat leaf-mould that suits it best. The bloom is a slender spike of white flowers in July; but now in mid-winter the beauty of the plant is in the high colouring of the leaves. Some are of a fine red tint throughout; others are spotted and marbled with red upon a ground of pale green, and have a border that is almost scarlet. One may look at a dozen leaves and find in each a different proportion

AN AUSTRALIAN SUNDEW (DROSERA BURKEANA) AT KEW.

ERICA CARNEA ALBA.

AMONG all our winter plants I value none more highly than *Erica carnea* and its variety *alba*. Long before the flowers attain to their perfect beauty they show thick on the pretty branches, and give us a welcome and ever-filled promise of a feast of pleasure in due time. The coloured form is generally a little later here than the white form that I have. This year is no exception to the rule. Christmas Day brought with it a welcome

and disposition of the red colouring, but all have the same aspect of neat and well-ordered beauty. It is perfectly hardy; a plant for all Great Britain, in cool rocky nooks or peat-bed edges.

The Blackberry crop of 1899. It is interesting to know that the Blackberry crop of last year was one of the heaviest on record. One man sent to the market fruit collected by neighbours to the value of £400. On many a waste acre this wholesome fruit could be grown with profit.

FRUIT GARDEN.

CULTIVATION OF BUSH APPLE TREES.

THE planting of bush Apple trees is considerably on the increase both in private and market gardens. Bush trees can be readily sprayed with insecticides for the destruction of insect and parasitic enemies. Moreover, their fruit is less liable to injury from wind, is more easily thinned and gathered; the tree also affords a quicker return and is more readily pruned than the standard. It is essentially the tree for the amateur, as a good collection of varieties can be grown on a limited space, and the pleasure of watching the development of their crops can be obtained without difficulty. A skilfully managed plantation of these trees, comprising a collection of the best varieties—such, for instance, as may be seen at Glewston Court, Ross—is a good object-lesson. Many might profit by inspecting such before planting if we draw conclusions from the badly managed trees to be often met with. Far too frequently trees are badly planted and left with but little further attention. Accommodating as the Apple undoubtedly is, its crops cannot be reaped in this way, and I will note briefly some of the most important points to be observed in its management. In

PREPARING FOR PLANTING.

efficient drainage should be ensured and the ground be trenched at least 2 feet in depth, keeping the top spit on the surface. This should be done early enough to allow the soil to become sufficiently settled before November, which is the best time for planting. When selecting trees, young ones that have been replanted the previous season should be preferred. If their roots are dry when received, they should be for a time plunged in water. In planting, place the trees 12 feet asunder, as this distance permits the sun's rays to penetrate amongst ordinary-sized bushes without space being wasted. Any damaged ends of roots should be removed by a clean upward cut and holes made sufficiently deep to allow the stem being placed in the soil to the same depth as before being lifted. Spread out the roots regularly in a horizontal position. The trees should also be firmly staked and mulched with short manure. In giving a description of trees for planting I omitted to mention

STOCKS.

Opinions about these are divided, but for the ordinary-sized bush and pyramid I prefer what is known as the English Paradise. Trees worked upon this are more moderate in growth, require less attention as regards root-pruning, and are more prolific when in a young state (too prolific in some cases, but this evil, if it may be so termed, can be easily remedied by thinning) than are those upon the free stock. The fine bushes at Cardiff Castle are upon the Crab and have never been root-pruned, and no trees bear better crops. It should be added that they have been planted twenty or more years, and possess heads as large as ordinary-sized standards. It would be interesting to know from Mr. Pettigrew if they bore freely or not when young. The

PRUNING

of the Apple is not difficult. In winter, after planting, cut back the young wood a few inches to

a bud pointing outwards, and this rule of cutting to an outward bud should be followed until the tree has grown to full size. The centre of the tree should be kept free, and crowding of branches, which is not an infrequent error, must be avoided. I will conclude these notes by giving a short

SELECTION OF VARIETIES

suitable for bushes and pyramids. Numerous equally valuable varieties are necessarily omitted. Dessert kinds: Beauty of Bath, Worcester Pearmain, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Adams' Pearmain, Ross Nonpareil, Braddick's Nonpareil, Egremont Russet, Brownlee's Russet, Allington Pippin, Claygate Pearmain, Court pendu Plat, Fearn's Pippin, and Sturmer Pippin. Kitchen kinds: Lord Suffield, on cold soil substitute Lord Grosvenor; Ecklinville, The Queen, Stirling Castle, Peasgood's Nonsuch, Lord Derby, Warner's King, Blenheim Orange, Bis-

A NEW APPLE: MR. LEOPOLD DE ROTHSCHILD.

marek, Lane's Prince Albert, Schoolmaster, Belle de Pontoise, Sandringham, Newton Wonder, and Danclow's Seedling. TITOS, COOMBER.
The Hendre Gardens, Monmouth.

APPLE MR. LEOPOLD DE ROTHSCHILD.

ONE of the interesting new fruits of the past year was this Apple, named after Mr. Leopold de Rothschild, and it is the result of a cross between Cox's Orange Pippin and that brilliantly coloured Crab, John Downie. It is a tree that should be planted in the future, not for the sake of profit, but to give beauty and colour to the garden. The fruit is yellow in colour and of a very agreeable flavour, pleasantly acid, not mawkish and mealy. The Crab parentage is more plainly marked than that of the Pippin. That this new fruit bears abundantly is evident from the illustration, which shows a tree heavily burdened with fruit.

STEWING PEARS.

A NOTE ON RECENT NEW KINDS.

IN *THE GARDEN*, vol. lvi., p. 512, "A. D." has a useful note on stewing Pears generally, and on two varieties, which recently gained awards of merit from the Royal Horticultural Society, particularly. With respect to the one he calls Notcutt's Winter Orange one would like to ask, Why Notcutt's? Winter Orange is an all-sufficient name that there is no need for disturbing, seeing that the Pear under that name is quite an old, though perhaps not well known, inhabitant of East Anglian gardens and orchards. The apathy shown towards stewing Pears pointed out by "A. D." must be the reason that it is not well known. For many years it was my most valued variety of its class, for, in addition to its good quality, it was always the best cropper, and I do not remember ever having had a failure. I showed it in March some years ago at the Drill Hall among a collection of Apples, but it was not then recognised by some of our greatest authorities on hardy fruit.

With respect to Double de Guerre, recognition has also been tardy. Loudon mentions it as having been introduced from Belgium before 1815. It is also figured and described in *Hort. Trans.*, 2nd ser., i. Loudon gives as a synonym Double Krijgs, and describes it as large, oblong-obovate, brownish russet and red; season November to February; stews tender, good bearer, and succeeds well as a standard. J. C. TALLACK.

PEAR NE PLUS MEURIS.

THIS is a good winter Pear where it does well, but I must agree with a recent writer that it is capricious as to locality and soil. In Suffolk I found it far from good, and it was generally used for stewing just before it ripened; only once or twice was it fit for dessert, and it usually showed spots of decay in the skin when it approached ripeness. At Galloway Mr. Day used to grow it well, and the high quality and large size of the fruits he grew were a surprise to me, and I can fully understand its being a favourite where it does so well, as it is always a good cropper. Galloway, though well north, has a favoured climate, and Pears that grow well there could not, perhaps, be recommended for culture further inland. Here in the midlands all the specimens I have seen of the variety in question have been poor and scrubby. A Pear that will surpass this and most other late varieties is President Barabe. J. C. T.

LATE WHITE GRAPES.

APART from the Muscat of Alexandria the supply of good late white Grapes is meagre, and, as far as I know, little progress has been made in this direction with new varieties. I do not think the old White Tokay and Trebbiano have been beaten when well finished, and another late white which is good when skilfully grown, as all late Grapes must be to get them really fit for table, is the old Raisin de Calabre, for it keeps splendidly and is handsome when well finished and clear in the skin. Mrs. Pearson does not appear to make much headway, as it takes as much growing as Muscat of Alexandria and is just as capricious; for one only sees it in good condition now and then. One would like to hear more about the keeping qualities of Lady Hutt, as if it would hang well, its popularity for planting would soon increase. I have never had any experience with it nor have I seen it hanging later than October, but I was impressed with its good quality for eating, and hope its qualities for hanging are equal. J. C. T.

ORCHIDS.

THE VANILLA.

NO one could make the Vanilla plant profitable in this country—at least, such is my experience—but it may be grown sometimes in the place of plants less interesting. There are only a few species, and I shall not consider at length more than one—that here illustrated—namely, *V. planifolia*, which is of chief commercial value; indeed, I think the others have no economic value whatever. The Vanilla is the only Orchid that gives fruit of any value, and though *V. aromatica* is sometimes grown for its fruit, I have been told by travellers who have studied the plants in their native habitat that the species illustrated and *aromatica* are so much alike, that they can be placed in the same class. The Vanilla is a native of the Tropics, and is a climbing plant with dark green rooting stems with fleshy leaves, and the flowers are borne on short spikes produced at the axils of the leaf and on the well-matured wood of the previous year. As regards the flowers, few Orchids are less interesting, as they are of a dull green colour, and the individual flowers on each spike are never open all at one time, and only last a few hours during bright sunshine. The pods when ripe are valuable for flavouring ices, chocolates, sweets, and form one of the best aromatic perfumes. The best of the species for its bloom is undoubtedly *V. Phaknopsis*, a most interesting plant and a species well worth culture in all collections, the flowers being large and beautifully coloured. The fruiting variety with us grows very freely indeed on the back wall of a warm house devoted to Bananas, and though we have it in other positions, such as on the end of warm plant houses, it is not so satisfactory, as it gets less sun, and I find that unless the new growth is well ripened by exposure to the sun, few pods are obtained the next season. There is, however, no difficulty whatever in getting ample growth, and slight shade must be given during the hottest part of the day and also abundant supplies of atmospheric moisture. We have frequently secured growth 10 feet to 12 feet long in a single season, showing its usefulness for covering a wall.

To make my meaning clear, one season, the sun being hot, we covered the roof with a permanent, though light, shade through the summer months, and were pleased to note the splendid growths made, also the better colour of the leaves; but the next year the crop of fruit was very poor, owing to the new wood not maturing properly. Anyone can grow this plant if given a brisk heat and ample moisture, not so much at root as in the atmosphere. The plant roots freely from the stems and fastens its roots on either wood or brick-work which affords moisture. About 6 inches of soil are provided for the roots. The soil, consisting of fibrous peat, sphagnum, charcoal, and clean potsherds, is placed in a kind of shallow box or trough. Every season early in the year a large number of the new growths are detached from the top of the wall and the base is placed in the beds, burying the air roots in the new material given. As the old growths have a tendency to get naked at the base it is well to

keep the wall furnished, and by annual planting of young growths we get fruit much lower down the wall than if the top growths were left, as there is always an upward tendency and the growth is stronger at the top. As regards the

PROPER TEMPERATURES.

a few degrees of heat more or less are of little consequence providing there is no lack of moisture. We frequently allow the temperature, where the Vanilla does best, to run up to 100 or more, at the same time syringing freely and flooding all parts of the house with water. The new growth is made from February to August, after the last-named date no shade of any kind being needed, and only during the hottest part of the day, say from eleven to two, in May, June, and July. From September to February the plants may be given a tempera-

ture of about 60 at night, increasing 5 to 10 by day, with less moisture at the roots and in the atmosphere. During the time the plants are in bloom they should be kept on the dry side as regards syringing.

G. WYTHES.

FRUIT OF THE VANILLA.
(Photographed at Spau House.)

I have not referred to the most important period, namely, when the plants are in bloom and the setting of the fruit, which is the most difficult part of the cultivation, as unless some knowledge is obtained of the structure of the flower there will be loss of fruiting-pods. I have never seen a single pod fertilised by insect agency, though I have kept a strict look-out, as we have never obtained pods unless fertilised by hand. Of course the work needs considerable care, and it is necessary to fertilise about mid-day just as the sun is shining brightly. In dull weather the pollen is not easily distributed, and care is needed that in opening or lifting the column no injury is done to the anther and stigma. The pods soon attain their full size and are usually from 5 inches to 8 inches long. A good set is from six to nine pods in a cluster. We

CORRESPONDENCE.

DWARFING PERENNIAL FLOWERS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, As one who has been interested in the article by Mr. E. H. Jenkins on the subject of cutting down *Pyrethrum uliginosum* and other flowers for the purpose of reducing their height, I would like to make some remarks on the general subject. I may premise, however, that the plants I have tried have been retarded in the time of their flowering, which is contrary to the experiments of your correspondent. The results may have been affected by different climatic conditions. With me they were in the same direction as cutting back *Delphiniums* or *Campulaks* to secure later flowers.

Generally speaking, I am averse to dwarfing our stately and effect-giving flowers, and prefer to have them as near their average height as possible.

Now that we have so many Asters of different heights it is almost unnecessary to cut these down, except, it may be, in the case of some of the Nova-Englie section, whose colours are not readily obtained among the Starworts of dwarfier habit. There are also so many Phloxes now-a-days, that it is not difficult to select a sufficient number of naturally dwarf habit, so as to avoid increasing the work of the garden unnecessarily by cutting them down. Of course, this cutting back can be done, but a garden generally supplies plenty of work without undertaking that which can be avoided. *Pyrethrum uliginosum* is quite a different flower, and one has seen it dwarfed by being cut back, to the great advantage of the garden. So far as I can at present remember, we have no flower of perennial habit which can take its place at the time it blooms. Unfortunately, in old gardens this period is too late to permit of this process being carried out satisfactorily. The true remedy will be secured by the seedling raiser giving us a variety of dwarfier habit which would require no cutting back.

S. ARNOTT.

POT CULTURE OF PLUMS

[TO THE EDITOR OF "THE GARDEN."]

SIR, It was pleasant to read at page 7 that so thoroughly good a gardener as Mr. Hudson was advocating growing Plums in pots, as it was an old weakness of mine. Last year, owing to the hard frosts in May, there was a very short crop out of doors, but we had good Plums from trees which had been in pots for about 45 years. I fear that these must be now feeling rather confined in their pots; they have not had a shift for some years and cannot have another, as they are now as much as a man and a boy can carry when put out to ripen their fruit. In old days at the Crystal Palace they thought most of size. I got Pond's Seedling and other big Plums so as to be able to show them, but sent in Transparent Gage, pointing out flavour, and got a second prize. I agree with Mr. Hudson that

this is a most desirable Plum, as, besides being of excellent flavour, it is very pretty in a dish. I used to think that why orchard houses did not become so general as they deserved is that they require hard work, especially in watering, and there is not so much honour and glory to a high-class gardener in growing cool-house fruit as first-class Grapes, Orchids, &c. I used to recommend to friends putting up orchard houses to put them in the hands of a sensible man, though not a highly-trained gardener, and give him the work and the credit. Two friends, great Orchid growers of those days, offered me their orchard-house trees if I would pay for their carriage. This confirmed me in the above opinion. I gave the same advice to Mr. Barron when he put up the orchard house at Chiswick, that was paid for by the results of the Royal Horticultural Society's show at Bury St. Edmunds. Many years ago, when Mr. Dunn showed me the Dalkeith gardens, knowing him to be a great authority, I asked what he thought of orchard houses. His opinion did not seem favourable. When I began to take the other side, he stopped with "I'm not speaking of *your* orchard houses." GEORGE F. WILSON.

Weybridge.

BOOKS.

FRUIT FARMING FOR PROFIT.*

THIS practical book upon fruit farming by a master of his subject has gone into a fourth edition, and we shall be surprised if further editions are not called for in the near future. Fruit farming has gained many adherents during recent years. Those who enter upon this industry do so with a greater knowledge than heretofore, realising that fruit culture is no mere fancy gardening that can be undertaken with a very superficial knowledge of stocks, varieties, and other matters necessary if the fruit basket is to be filled to overflowing. Such books as Mr. Bunyard's do much towards promoting a proper knowledge of fruit culture in its many forms, and may be recommended as a guide to the beginner and to the many who have failed through want of knowledge. It must be remembered that fruit farming is an industry requiring careful training, and is not always a gold-mine. So many false statements have appeared to the effect that fruit farming spells "fortune," that the more quickly they are upset the better for those who embark in the business. That fruit growing is a national industry of importance is unquestionable, and books of the same worth as Mr. Bunyard's will make smoother the beginner's path.

The following extract will show the nature of the information given. It concerns

FRUITS NOT MUCH GROWN.

and forms chapter xv., p. 95.

"No one can see the laborious efforts of the Vine growers on the Continent, with their miles of terraced hillsides where a lodgment is effected for their favourite fruit by sheer labour, without thinking that there are many wild places in England where not only Grapes, but Figs and possibly Peaches could be grown in quantity. In Devonshire and the south there are many wild places where, with protection, much useless rocky land could be utilised, and old disused quarries, gravel pits, and sand-holes be made luxuriant; while there are many ponds and damp situations which could be planted with Quinces. These sell well, and a taste for them is growing. Quince marmalade is a very acceptable relish; and a few trees about the farmyard and duck pond would not only be lovely in flower, but produce fine fruit. To return to our plan.

"Grapes. The white Sweetwater and Gamay Noir with the old Black Cluster are generally very

acceptable, and would be more so were they better cultivated and the bunches and berries thinned out. They would then ripen and have larger berries. Many old buildings and sheds are made picturesque by a covering of Vines; and in the case of quarries, &c., they could, perhaps, be made to hang over the edges on wooden frames, if the soil was not sufficiently deep to plant them below; the large south or west gables of houses, barns, &c., could be filled with Vines, and if the situation was very good, Miller's Burgundy and Black Hamburgh could be tried, as well as the White Muscadine, Chasselas Vibert, and other hardy white Grapes. Under glass, if they can be well done, Grapes do pay. The importations of fruit from the Channel Islands and the Continent has brought down the price of hot-house fruit produced in this country by one-half; and further, so many gentlemen's gardeners have orders to sell their surplus crop, that the amateur has little chance of competing with them; though, if the handy man about the garden, or, as sometimes happens, one of the family take a pleasure in looking after such things, they may be grown to advantage, but we should prefer to sell the crop at a price to a dealer and let him take the risk. The high prices good Grapes realise in our large cities and towns, and the low figure they make wholesale, is a most dismal outlook for growers just starting; and as those princes of culture, the market florists, have now taken up the growth of late Grapes by the acre in their usual energetic manner, this matter must be thoroughly weighed before investing in 'glass.

"PEACHES, NECTARINES, AND APRICOTS.—These require so much care on walls, and the spring climate has for several years been so against them, that they cannot be recommended for open-wall culture at a profit, as when a crop is taken, it may be general, and prices consequently low. We have found the large-growing late kinds, such as Dymond, Sea Eagle, Barrington, and Princess of Wales, the best. Among Nectarines, Lord Napier and Elruge, white fleshed, and Humboldt and Rivers' Orange, yellow fleshed, are the best. The orchard house system of culture gives better results. Here with partial heat, or even without it, good crops are taken, and when water is abundant for syringing, they can be well grown. We would prefer, however, to have them trained flatly, 4 foot under the glass; and if attention is paid to thinning the shoots and fruit, wonderful examples are produced. The best results are obtained from trees planted out, and the marvellous 18-oz. fruit grown at Bexley have astonished all growers. Remember always to send Peaches to market before they are fully ripe. As before alluded to, we are inclined to think early Peaches might be grown on bushes in favourable spots in the open air,* especially where there is a mixture of chalk in the soil. Probably if for a few years tacked to a sandstone bank or rock, and then allowed to grow naturally, merely thinning the boughs, a result might be obtained. The same remarks apply to Apricots, but the Orange and Breda only should be experimented on. Nothing is more injurious to these stone fruits than high cultivation in outside trees, as we generally get a wet time after the first growth is completed, and they then make fresh wood freely, which our short English summers prevent from becoming ripe enough to resist the rigours of winter. Probably a covering, such as is used for Vine borders, would obviate this, by throwing off excess of moisture from the roots. In all cases the soil must be firm, and no stimulants should be used till the fruit is set.

"Figs are like Tomatoes and oysters, a taste for them has to be acquired, and when a person begins to like, they become greedily fond of them. In many parts of Kent they grow well on bushes or standards, on land where there is but little depth of soil, and only require a partial thinning of the branches annually, while along the southern and western coast of Britain they flourish and make trees. They delight in a dry corner; the hardiest are the Brown Turkey, Malta, and Marseilles, but

Osborn's Prolific and others might be tried. When Fig trees are heavily cropped, a free use of liquid manure in a dry season will assist the fruit into size. As in most large gardens a Fig house is now the rule, there will probably soon be a demand for a cheaper class of fruit; none is more acceptable on the breakfast-table. Good Figs were 12s. per dozen in May in London.

"A very interesting account of the Fig orchards in Sussex appeared in THE GARDEN, May 10, 1890, from which we extract the following notes: "The best kind for open-air culture is the Brown Turkey, and the trees are allowed to grow naturally without pruning, and among them is one said to have been planted by Thomas à Becket, which has barely survived being struck by lightning in 1885. They prefer a gravelly subsoil, and lime rubbish and similar materials are added as a dressing to the rich surface loam. Just before ripening, the Figs are placed into bags, to protect them from birds, otherwise they are sure to be spoiled. The larger trees have stakes and cross pieces to keep the boughs from the ground, and so greatly are they now appreciated, that they sell for as much each as they formerly fetched per dozen." Chalk rubbish appears to form a good foundation for their roots to work in, and no doubt the introduction of broken bricks, stones, cinders, &c., would keep the trees from making too gross shoots, and enable them to ripen their wood.

"MULBERRIES. These are seldom seen in market, they so soon spoil after picking. So far as we know, no use has yet been made of them as a preserve. They may become useful in dyeing, the stains being very intense.

"BLACKBERRIES. One of our most delicious fruits as a preserve—in fact, with cream, quite an exotic dish is produced; but these are generally suffered to grow wild. Many stony banks, probably the heaps of refuse from quarries, chalk works, lead works, &c., might be planted with them to advantage. The jam-maker who first had a stock would be able to command a large price after the flavour became known. On Lord Sudeley's estate the Brambles are allowed to grow in the hedges, and Blackberry jelly and jam have yielded large returns. They are also cultivated in Kent. The selected British one is very fine, but the American varieties have failed to succeed in this climate. The cut-leaved kind is very productive and free in growth. Many sides of railways, roads, &c., would grow these well. Can be propagated by cuttings made from the roots and long shoots. The new Logan Berry will be a gain in this direction.

"QUINCES might be planted as before alluded to. Cheap trees of these as two-year-old cuttings could be at first planted, or half standards. They require no pruning for some years; merely thin the branches. The best kinds are the pear-shaped and Portugal, both large-fruited varieties.

"MEDLARS.—We have sold trees of these for market. The large-fruited kind forms a flat-headed tree, and the Royal an upright tree; the former is the best for market. As the green fruit is quite uneatable, they could be planted in the hedgerows; and those who are expert could graft them on the Whitethorn already there, but to save time they should be purchased from a nursery. They are marketed in quarter sieves and in punnets, and are reputed to produce a fair return, and are becoming greatly sought after both for dessert and jelly.

"BILBERRIES, CRANBERRIES, and WATERCRESSSES are crops which those having especially suitable places could cultivate, and even the Heath could be grown for broom-making with advantage."

THE GARDEN ANNUAL.

This useful annual, almanack and address book for the present year has been recently published. It is an excellent reference book for the garden library and full of good general information such as a gardener requires occasionally in his work. Addresses are given of gardeners in the British Isles, nurserymen, societies with their secretaries, and the new plants and fruits of the past year are recorded also. It is published at 37, Southampton Street, Strand, W.C., and will be sent post free for 1s. 3d.

* Fruit Farming for Profit. By George Bunyard, The Royal Nurseries, Maidstone. From the author, 2s. 6d., or tree by post, 2s. 9d.

* Wonderful crops have been obtained by Mr. Blackmore, at Toddington, from the early American sorts, but he states that it was not till the trees were 8 feet high that they cropped and perfected their fruit.

THE GARDEN.

No. 1470.—Vol. LVII.]

[JANUARY 20, 1900.

FALSE IDEALS.

NOTHING is more frequent in seed lists than to find the words "dwarf and compact" used in praise of some annual plant, and used with an air of conviction, as if to say: "There! now we have got it 'dwarf and compact.' We have done our whole duty by it; buy it and grow it, and be happy."

Is it an ungenerous and ungrateful act on the part of some of us that we are not content to accept "dwarf and compact" as the end of all beauty? Is it not rather, as we venture to think, a question that demands the most careful consideration and the exercise of the most well-balanced judgment in the case of each individual kind of plant that is commonly grown for the adornment of our gardens?

For planting beds in a geometrical garden, where the object is merely to fill spaces of certain shapes with a mass of some chosen colour, these dwarfed plants are all very well, and no doubt this is a way of gardening that has its uses. But because the dwarfed form may suit such use in perhaps one garden out of a hundred, it is not a reason for denying the best possible form that the plant might have to the other ninety-nine. May it not be one of the many cases in which the practice of what is easiest has falsely taken the place of what is best?

For any one of the great firms who benefit us by growing acres upon acres of beautiful plants for seed, to accept as a general article of faith that all annual plants are the better for dwarfing, is certainly to adopt an attitude of mind which does not put an undue or fatiguing strain upon the imagination.

It is, no doubt, very easy to make this mistake, for here and there is a plant that just does want a certain degree of dwarfing, and when such a form occurs in a seed-bed, the condensing of the mass of bloom at once gives the dwarfed plant the appearance of being better furnished, and the idea, adopted with good reason in the case of one seed-bed, is apt to draw away the mind from other considerations, and to fix also, in the case of others, on that special quality as the one most worthy of encouragement. So it goes on from plant to plant, until it has come to be much too readily accepted among seed-growers, seed-merchants, and gardeners that "dwarf and compact" is necessarily a term of praise, and in the greater number of cases the most desirable habit for an annual plant.

It is true that with many plants we are still at liberty to choose, and that in seedsmen's lists we are offered both tall and dwarf kinds of such plants as Larkspurs, Marigolds, Zinnias, Salpiglossis, and so on. But, on the other hand, there are good things of which only the dwarfed forms remain, and though a great many people who love their gardens would be glad to have the plants in the bolder shape, the desired form is denied them.

Part of the difficulty also comes from the pursuit of novelty as a quality that is thought to be desirable in itself. When, in the course of its cultivation, a plant does come to have some high degree of beauty of form and flower, how rarely do the producers seem to recognise the fact that here is a beautiful thing to be treasured and guarded, and not driven further into directions that detract from that beauty, merely for the sake of some newer, but not necessarily better, development.

During the past autumn we have been more than ever struck with the beauty of that grand autumn plant, the French Marigold. To the end of October, and even into November, in the half-light of the afternoon of early winter, the gorgeonsness of these fine flowers was unequalled by anything else in the garden. The 2-foot-high plants, of bold and handsome growth, were generously set with glowing bloom of ample quantity, but not crowded. One kept coming back and back to them with a sense of thankful admiration, and a conviction that here was the very best this good plant could do. The individual flowers, of deepest orange and rich mahogany, had the folds of the petals just close enough to give the flower the utmost richness, and to display the glorious colour to the very best advantage. Beside these grand things it was impossible to see without a feeling of regret for good effort wasted, some others, that to judge by illustrated seed-lists, would appear to be considered of more orthodox excellence. "Dwarf and compact" they certainly were, but without an atom of grace or beauty and with tightly folded flowers, looking like sections of cut gingerbread.

Some whole families of favourite plants want deliverance from this thralldom. A note last week dealt with this question as it relates to China Asters, but we also want bolder forms in all the families of Stocks. We want the whole plant more free of growth and more branched; we want them more beautiful. What Wallflowers are so fine as the great bushy ones in cottage gardens on a fairly stiff soil! What dwarf garden Wallflower can compare with them?

The over-doubling of flowers is another matter that is often fatal to beauty. Many a flower is the better for a judicious degree of doubling, but when it is carried too far it turns what should be a handsome flower into a misshapen absurdity. This has been done in the case of Zinnias. In this fine thing moderate doubling is a gain, on a well-grown plant a couple of feet high. But there is a monstrous form where many rows of petals show one above the other. In this the flower is robbed of all its natural beauty and becomes an absurd cone of quite indefensible ugliness, and it is all the more deplorable an object when this monstrous flower is grown on a dwarfed plant. The orthodox Hollyhock is also much too tightly doubled, so that it becomes a tight wrinkled hemisphere. The beautiful Hollyhock has a distinct wide outer petticoat, and the inner portion is not so tightly packed but that its component petals, though closely grouped and loosely crumpled, admit of the free play of light and colour.

The undesirable influence of a false ideal and of the rage for novelty, rather than a calm judgment of what is most beautiful, is also seen in the matter of colour. Some flowers have naturally only a tender tinting, which seems to be so much a part of their true nature, that attempts to force them into stronger colouring can only detract from their refinement. Such a plant is the delicious Mignonette, with a tender colouring that seems like a modest self-deprecating introduction to its delicious and wholesome quality of sweetness. The slightly warmer shade of the anthers in the plant of normal tinting, with a general absence of any positively bright colouring, is exactly in accordance with the plant's true character, and with that modest charm that gives it a warm place in every good gardener's heart. But when, as in some of the recent so-called improvements, the graceful head is enlarged and condensed into a broad, thickened squatness, with large brick-red anthers, that modest grace that formed the essence of the sweet flower's charm is entirely gone, and in its place we are offered a thing that has lost all beauty and has only gained a look of coarseness. These broad, thick blooms have also a suspicion of rank quality about their scent that was never apparent in the older forms.

All honour and grateful acknowledgment are due to seed growers both at home and abroad for the many grand plants that we owe to their careful labours. We know that

they will take our remarks in good part, and after all it is only by letting them know what is wanted that we may expect perhaps some day to get it.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

As our report on another page shows, this institution, thanks to the solid work performed by all concerned in its management, has flourished exceedingly during the past year. There must be no standing still. This organisation should increase greatly in usefulness and prosperity, as various country branches are founded to carry its good work into districts far removed from the metropolis. Its work is not "local," though when the chief business is centred around a London office, those far removed from its headquarters are thus apt to regard it. For that reason the great movement taking place of establishing branches in various parts of the British Isles should be encouraged, and the gardener urged to support an organisation founded for his benefit in times of trouble and distress. But gardeners give somewhat half-hearted support to the institution, partly, we think, because they have never studied its working and may be forgetful that health and vigour are uncertain. The annual subscription is small and may generally be afforded by gardeners of all degrees, and it is their duty to think of possible troubles in the future, when the institution may be appealed to for succour.

This benevolent institution is for gardeners, and gardeners only, and they should set their part in contributing towards its maintenance. The past year of progress may not continue in 1900: the nation is plunged in war, and the purse-strings untied for our soldiers fighting for its welfare across the seas. Let the gardeners, therefore, play their part in helping this excellent institution, remembering that its continued and increased prosperity means greater opportunities of giving assistance in time of need. We hope the annual subscribers will increase, as these form a solid foundation, and those who intend to help forward the institution may be reminded that the expense of management (£700) is covered by the interest derived from invested funds, and there yet remains a further £200 from the same source for relief. Every penny received each year from subscriptions and donations therefore goes to benefit the gardener or his widow in distress. During the past few years its good work has been extending, and it remains for the gardeners of the British Isles and those interested in horticulture to declare whether this happy condition of things is to continue in the future.

SOME WELCOME ENCOURAGEMENT.

It is extremely gratifying to see how THE GARDEN'S old friends are coming forward to support it in its new life. We take it not only as evincing general interest in horticulture and as a kindly desire to strengthen the hands of those who are now responsible for the paper's management, but as an acknowledgment due to the good work it has done in the past. Of this we have a signal proof, as not unworthy of expression by one who holds his high office, in the sonnet that the Poet Laureate honoured us by writing. No one loves a garden better than Mr. Austin, or has written of it with more delicate and delightful sympathy. Other names honoured in literature will also appear in our pages, and we are receiving cordially sympathetic

communications not only from those who hold the highest places in the horticultural world, but from eminent botanists and other men of science whose learning bears upon the subjects we have in hand. - Eds.

THE FRUIT GARDEN.

LATE PEARS.

IT is not enough that there should be plenty of good Pears. We have such in abundance, but the bulk of them are ripe and over by the end of November, and too often what is left is of inferior quality. To have really good Pears that, besides being of fair size, are clean, handsome, of good colour, and have soft smooth flesh, full of juice and of fair flavour, up to the end of February is indeed difficult, and myriads of even fair Pear growers fail in that respect. At the last meeting of the Royal Horticultural Society one of the ablest Pear growers in the kingdom (Mr. Woodward, gardener to Mr. Roger Leigh, Barham Court, Maidstone) placed before the fruit committee very fine samples of an old variety, Passe Crassane, usually regarded as a December Pear, and the well-known yet comparatively little-grown Doyenné d'Alençon. This latter Pear has been in commerce many years, but till the meeting of the 9th inst. had never received any award from the Royal

A GOOD WINTER PEAR (PASSE CRASSANE) REDUCED.

(From a photograph of fruit shown by Mr. Roger Leigh (gardener, Mr. Woodward), Barham Court, Maidstone, at the last meeting of the R.H.S.).

Horticultural Society, probably because never previously shown in such good condition. But because so shown, and found to be of such comparative excellence on the above date for the time of year, an award of merit was granted to it. These are not, of course, the only good late Pears in cultivation. A further list of capital varieties, where they be well grown, may be found in *Easter Beurré*, *Josephine de Malines*, *Marie Benoist*, *Beurré Rance*, *President Barabe*, and *Ne plus Meuris*, so that there is no lack of good late Pears. But how few can obtain such superb samples as Mr. Woodward does, and the illustration given of *Passe Crassane* shows what these Barham Court late Pears are. But whilst too many persons would attribute the success there obtained to soil or climate, the grower attributes it to cultural attention. The trees of both *Passe Crassane* and *Doyenné d'Alençon* are twenty years old. They are of the usual horizontal-trained form and are on a west wall. It may be said that a wall having a west or slightly north-west aspect is the very best for late Pears. Each winter the soil, some 3 inches or 4 inches deep, is stripped from over the tree roots, and on the latter is placed a good dressing of half-decayed manure. Some of the soil is then cast back over the manure. That dressing has a very potent effect on the swelling and nutrition of the flower buds. Then during the following season,

especially when the fruits are swelling, and particularly in the autumn, the roots get occasional soakings of water, which do wonders in helping to swell the fruits. When the bloom is set in the spring and fruits are well formed, thinning takes place early, and whilst that process is not hard, yet it is enough to enable good fruits in ample quantity to be produced. Thinning is too often left late, when it had better have been done a month sooner. As the fruits attain size (and under such good treatment they soon become double the size late Pears ordinarily are), that they may hang on the trees as long as possible, a piece of raffia or soft twine is tied to the fruit stem and fairly tight to the branch from which the fruit hangs. This is found most helpful in keeping the fruits attached to the tree to the very last moment of their maturation, and with late Pears that complete maturation is a matter of the first moment that is too seldom considered. Even should the fruits become detached from the tree, they are held safe and do not fall and become injured. A. D.

PEAR PASSE CRASSANE.

This excellent Pear was shown in such fine condition by Mr. Woodward, of Barham Court Gardens, at the recent meeting of the Royal Horticultural Society, that a few words as to its value for use at this season, when there are so few really good Pears, may not be out of place. It has been grown for nearly half a century in this country, but I fear in a very few gardens can one meet with such excellent specimens as the fruit illustrated in THE GARDEN.

As the name suggests, it is of continental origin, having been first fruited at Rouen some forty-six years ago, and it has only recently been recognised by the fruit committee of the Royal Horticultural Society, receiving a first-class certificate. It may be asked why such an excellent fruit as regards its flavour is not better known, and my answer is that in many gardens it is not nearly so free bearing as one might wish, and in others it does not crop at all if the trees are hard pruned summer and winter, and even in the most favoured localities it needs wall protection.

I am able to give Mr. Woodward's mode of culture, and it is one very easily carried out. It consists in not pruning too hard and allowing the trees to make a season's growth without stopping or training. Treated thus, I am aware the trees do not present the neat appearance usually seen in a well-kept garden, but appearances must not in this case be considered, and though the trees are cut back in winter, by leaving the wood till that season the buds at the lower part of the trees give fruit, which if the trees were cut back in summer would not be the case.

Even in the renowned Kent soil this variety is grown on a west wall, and I think Mr. Woodward is an advocate of root-pruning this variety, and there can be no question whatever as to the quality of his fruits, as those illustrated were little inferior to those of *Doyenné du Comice* at its best in December. I have tried to grow this variety as a cordon, but failed, and, of course, my failure cannot be wondered at if the trees need the free growth as allowed at Barham Court. I have also tried trees double-worked, but failed to obtain fruits of the size or quality expected; but it does not appear necessary to have the trees double-grafted, as the Barham Court trees are on the Quince stock, and they appear to crop every year and give beautiful fruit. Of course, soils may be answerable in some cases for the want of success, but there can be no doubt whatever that some varieties will not bear such frequent pinching and cutting back as others. Only to-day, when looking over some young bush trees of Pitnaston Duchess, I was lamenting the necessity for such hard pruning, as the points of the growths were a mass of flower-buds, and to keep the trees within bounds it was necessary to take three parts of the fruiting wood away. It is useless to cut the top-growth and allow the roots to ramble at will, so that root-pruning will occasionally be found necessary.

GEO. WYTHES.

DAFFODILS at WARLEY PLACE.

Essex is by no means notable among English counties for its private gardens, the soil over much of its acreage being stiff and cold, and its levels flat and unpicturesque. But even if it contained no other garden worth a visit, Warley Place alone would relieve Essex of being a negligible quantity to appreciative gardeners. The garden is not of the largest—in my humble judgment it is all the better for this limitation of space—but it would probably be impossible to find in England an equal area more absolutely crammed with all that is most beautiful and choice among plants. Indeed, if it were possible to have a quarrel

view, and the garden is fortunate in comprising hill and dale within its modest boundaries, and a soil of super-excellent sandy loam. The Ivy-clad house, built on an ancient foundation, contains a wealth of beautiful things, witnesses to manifold accomplishments. The little chapel may stand as an example of tasteful and restful simplicity, and the whole history of the instrument-making craft may be learned from the rare collection of the music room. The remarkably complete horticultural library tells that the garden has effected a lodgment within the house, and testifies to the truth that other tasks and pursuits, however full and diverse, are overruled and held in subordination to the passion for gardening

rockeries, mostly mean and incongruous stone heaps, which are entirely out of keeping with the gentle lines of English landscapes. But at Warley you walk, all unconscious, over a stretch of green turf, purpled in February with sheets of the rare wild Crocus, until it suddenly slips over into a miniature stream-bottomed valley. The alpinists have entered into possession of their home with a zest which shows how well their wants have been understood. As to the fulness of their numbers, I have a vivid recollection of the arduous task which that past-master of nomenclature, Mr. Wolley Dod, found one spring day in naming the rarer plants. At the lower end of the ravine the streamlet flows through a cunningly built cave,

POLYANTHUSES AND OTHER NARCISSI AT WARLEY PLACE.

with the head gardener, V.M.H., it would be on the score that she can scarcely herself keep accurate count of the contents of so full a treasury, for this is not her only garden. The care also lies upon her of Tresserve, that terraced bower of glorious bloom, fronted by the purple mountains and blue waters of the Savoyard lake. Not that any overcrowding is implied by the word "crammed," but every foot of ground is occupied, as it should be, by some plant which desires that spot and no other for its full contentment; yet none are stinted of soil or sunlight, and there is nowhere any sacrificing of general effect to petty detail.

The site of Warley Place commands a noble

where it has once taken possession. Out of doors the most eminent feature is, perhaps, the alpine garden—if, outside Ireland, anything should be called "eminent" which is sunk below the surface-line. When its construction was being planned, I believe Miss Willmott was counselled to build up the rockwork on the natural surface, but most wisely and success-fully acted on her own better instinct and knowledge, and cut out a deep ravine for its reception. Not only are drought and wind thus largely warded off, but a standing artistic difficulty is solved. Very many otherwise charming gardens seem to me to have been grievously marred by the rage for these

the dimly-lit and ever moist abode of the choicest Filmy and other Ferns.

The true gardener comes to regard plants much as the Roman poet regarded humanity. "I am a man, and nothing human comes amiss to me." If Miss Willmott were pressed to name her favourite flower, she might probably answer, "Every flower in its season." Yet I venture, without her leave, to credit her with a special affection for Roses and Daffodils. Of the former, that is to say, Rose species, the Warley collection is probably unique. Very rare and interesting Roses are met with everywhere on the place, and certainly the search for any lost or out-of-the-way kind would be more

hopeful at Warley than in any other European garden. As to Daffodils, the accompanying photographs are proof enough that at Warley they receive no niggardly share of regard and space. The immemorial existence on the estate of the Lent Lily in complete happiness was rightly taken as an indication of a good Daffodil soil, and a beautiful planting in the grass of the most effective varieties has given results such as are here shown. The picture containing the seat round the Oak shows the value, at a season when the grass is otherwise flowerless, of large, irregular masses of Daffodils, and especially of the Tazetta or Polyanthus Narcissus. This latter flower has of late, for

light, their massed clusters of bloom have an unrivalled quality of glistening pearliness, while their fragrance is delightful in the open air. In another photograph the lighter effect is seen of the starry *N. incomparabilis* and the value of Daffodils against a dark background. But Daffodils are not treated merely in this broadcast manner at Warley. A Daffodil dell has been consecrated to a noble collection of the finer kinds, planted informally in clumps and in small beds of varying size and form cut out of the natural turf. In the Warley loan the bulbs make that somewhat short, broad-leaved growth, with the flowers showing well above the foliage, which Daffodil lovers greet as a

found a home with which they appear well content. That quaint and generally disobliging plant, *N. cyclamineus*, may be seen in considerable colonies, thriving and yielding unusually large flowers. *N. triandrus*, too, is a favourite, and repays the liking and care bestowed upon it. The photograph shows how appreciatively the fastidious requirements of a plant such as this little Spanish Daffodil are understood and indulged at Warley Place.

G. H. ENGLEHEART.

THE WINTER GARDEN.

Our gardens in winter have, speaking broadly, not received that thought and attention that they really deserve. "Now is the winter of our discontent" need not be true of our open-air gardens in December or January, even though they must lack, perforce, the brilliant floral colouring of rosy June.

One of the facts most obvious to those who look at Nature, at our woods and hedges, and stream-margins in winter, is the delicate forms and the tender shades of colour they display in sunlight or in shade. Every artist is aware of this fact, and our tree-planters and landscape-gardeners fail, inasmuch as they but too often confine their attention to spring and summer effects, leaving the late autumn and winter to take care of themselves.

It is not always so, I know, but still, as I have said, it is too often the case in even what are in other ways considered to be our best gardens. Now and then some attempts are made to gain wintry warmth and colour by evergreens, such as Golden Yews, *Euonymus*, Hollies, &c., but even these cannot, as I think, compete with the subtle colourings of some deciduous trees and shrubs, such as silver or paper Birch, golden or Cardinal Willows, the Dogwood, and free-fruited Roses, especially the Sweet Briar.

Red, yellow, and orange-fruited Hollies, *Pyracantha*, *Pernettyas*, and *Cotoneasters* often light up very brightly in the winter sunshine, and more effective use might be made of the Japanese winter Jasmine, the Jonquil-like yellow flowers and Rush-like stems of which contrast effectively with the bronzy leaves of the common *Mahonia*, or with Ivies of various kinds, especially with the dark leaves of *Hedera atropurpurea*, the so-called Black-leaved Ivy. It is during the mild winter season that all the hardy Bamboos are at their best, especially in sheltered glades or dells and near to water-margins.

I know an old garden near the sea intersected by sheltering beechen hedges, 20 feet or 30 feet in height, and these stand out against sea and sky, being when sunlit of a rich warm old gold or warm russet hue, and the same is true in a minor degree of the pleached hedges of Hornbeam, now, alas! so rare in gardens.

In Sussex there is a broad-margined carriage-drive from which extensive and varied views o'er wood and downs and hazy blue distances are obtained. It is fringed with Gorse, Dogwood, Willows, and silver Birch, with here and there clumps of Broom and spreading carpets of different kinds of Heather (*Erica*), and the effect is very delightful all the year. The small low-growing autumnal Furze often flowers through the winter until the larger kind appears, while the Sweet Briar, so fresh and sweet in spring, is now brilliant scarlet with its sealing-wax coloured heps. The Scotch Fir, either singly or in groups, never looks better in colour than during the winter, and the same may be said of all the kinds of conifers and of the various sorts of *Arbutus*, and especially the large and

STAR DAFFODILS (*NARCISSUS INCOMPARABILIS*) AT WARLEY PLACE.

some inscrutable reason, fallen under a quite undeserved ban, as though of merit wholly inferior to other Narcissi. It is true that the Tazettas are not all hardy, but several of the very best, such as Grand Monarque and Gloriosa, are perfectly frost-proof in turf anywhere in the southern half of England. And seen on a showery spring morning, under broken

sign of well-being, and there are few lovelier sights than this dell on an April day of cloud and gleam. In nooks of the alpine garden and other spots are Daffodils of still greater rarity and beauty, many of them not to be found elsewhere. Some of my own seedlings, I am glad to say, particularly the waxen, Fuchsia-like hybrids of *N. triandrus*, have here

handsome *A. andrachnoides* or *A. hybrida*, with its handsome leafage and flower-clusters and its rich red stems.

One of the richest and most remarkable of winter effects I ever saw is that afforded by the Sea Buckthorn, as it grows on the sand-hills near the sea at Countown Harbour, County Wexford. It was introduced near fifty years or so ago, and has spread about freely, some of the older specimens under which one can walk, others only a foot or two high, but all densely covered with orange-coloured fruits, visible and effective half a mile away.

The river Liffey, at Strallan Bridge, is a glowing picture all through the winter with crimson Dogwood and crimson and golden Osiers, with here and there a silver Birch. The same is the case at Carton, Kildare, where the islands and lake margins are likewise planted with Willows and Dogwood, which glisten after rain, or glow with rich colour in the wintry sun, while wild ducks by the thousand sweep round in their flights or settle to roost there.

Longfellow says (or is it Oliver Wendell Holmes?) that deciduous trees are like beautiful big children, and that Nature—the dear old nurse—dresses and undresses them every year. To many, a stately tree in winter has all the beauty of fine sculpture. The subtle grace and noble proportions are seen all the better when their leafage is away. A group of tall Scotch Fir, or of Beech, or of the silvery-barked Birch—MacWhirter's fair "Lady of the Woods"—is worthy of close study in all the stages of illumination they undergo on every winter day. In rain, in snow or frost, in bright sunlight or in misty shadow, in strong winds or in dead calm, all trees possess their beauty as they stand up against an ever-changing sky.

I once saw the great plumed heads of the Swamp Cypress at Syon House on a grey winter day, and as they towered above the mist and fog they stood out clear as an etching or photograph, and added a touch of sombre mystery to the scenery of Thames-side not easy to describe.

In order to obtain the best effects we must group our trees, and not dot them about singly, as is now too often the rule. A single tree is often very beautiful, but let us have, wherever space is ample, groups as well as single specimens for variety and contrast. In all but the most sheltered situations a group of any one kind of tree will grow quicker and become more effective sooner than an isolated specimen, a fact probably due to their mutually sheltering each other. Again, no two groups should be planted exactly alike or at the same distance apart; they should be arranged with feeling, and not by rule and line. Very picturesque groups are often formed when trees are self-sown, or they may be made by judiciously thinning out trees from groups or clumps originally planted in a formal way.

I remember in Ireland a rough rocky valley that formed part of a demesne and came in full view of the upper windows of the house. The bare rocks on either side lacked colour and variety, but on this being pointed out to an old forester, he at once proposed a remedy. "Sow the sunny side with Gorse and Broom," said he, "and the shady side with Birch and Scotch Fir." The owner at once had it done; indeed, having an inborn feeling for landscape beauty, he directed the actual sowing operations himself the following spring, and the result is that a common-place valley is now one of the prettiest and brightest views on the place.

In districts where our native evergreens are absent, they may often be introduced for shade and shelter with good effect, and on cold and

exposed sites will often thrive where exotics fail. Yew, Box, and Holly but rarely suffer from our hardest winters, and make the best of hedges and shelter-belts whenever such are desired for other low-growing things.

A curved river-margin I know in Norfolk is fringed with pollard Willows and coloured Osiers, which slope down to the water's edge where the common Reed (*Arundo*) and black-headed Reed Mace (*Typha*) rustle and sway in every breeze. Between the pollard Willows

perceive that the forces making for life are greater than those which at present make for the mastery of winter. Roots are pushing forth fresh rootlets; sturdy or delicate shoots are rising from the "mother root," and will bring, in due course, graceful or stately stem and charming or noble flower. Winter, with all its dreariness to those who love hardy flowers, is full of budding hopes. It is at this season that we can enjoy to the full the pleasures of hope. The garden year is all before us with its treasures of leaf and flower, colour and perfume—delightful to our eyes and charming us

A COLONY OF NARCISSUS TRIANDRUS AT WARLEY PLACE.

are groups of Dogwood and Bamboos, and when the afternoon sunshine falls on these the colour effect is nearly as soft and as tender as that of a rainbow, and any truthful painting of it would be disbelieved and voted overdone.

It is to be hoped that winter gardening will be soon carried out as well as may be in our London and suburban parks, where all who see may be led to take note of the many hardy trees, shrubs, and other plants that are beautiful in the open air even during the cold winter days.

During recent years much good planting in this direction has been done at Kew, and all interested could not do better than visit open-air Kew during a winter's day, and note for future use the many plants that there lend themselves to the hand and eye of the landscape gardener. Here, at least, may be seen most of the beautiful hardy vegetation that by form or colour of stem and branch, leaf and berry, or even actual flower, lights up and cheers our gardens during the winter days.

Dublin.

E. W. BURBIDGE, M.A.

When winter rules almost unchecked we are apt to forget that his reign will soon come to an end. If we look at our plants we shall see all around us the evidence that the power of the season is insufficient to hold for long in thralldom the forces of spring. The swelling buds, the points of the plants which, even at this early time, are thrusting themselves through the cold earth, are tokens that the time of desolation is fast giving place to the era of brightness and gladness. If we could see underneath the hard surface of the soil we should

with the fragrance they exhale. These hopes are no mere day dreams; they are built upon the experience of the past.

Yet we need not dwell only on the pleasure of the future. It is possible even now to draw from the garden and its surroundings joys of the highest kind. They may be chastened by the hardships of the time, but they are joys none the less. If the eye has been opened to see the numberless charms of Nature, we shall not want for pleasures. The future may not be for us, but the present is ours and it is full of interest. The chill breath of winter has robbed us, it may be, but we are not left desolate. There are yet a few flowers; there will soon be more. There are plants and shrubs and trees whose leaves are proof against the cold; from their colouring and their beauty of form we can draw stores of pleasure and knowledge. There are fruits from the flowers of the past; precious relics are they in their sweet memories, and beautiful and cheering in themselves.

Then have we not the beauty of our deciduous trees, which now stands revealed in a different aspect from that of the sweet summer-time? Their grandeur and nobility, then robbed with grace, now show in all their greatness. Rugged it may be, or, as with some trees, delicate and graceful yet, but it is beauty still. As we gaze upon these trees and admire their noble trunks, their brave branches, and the tracery of their twigs, we think that, after all, winter has his glories, if summer has hers.

S. ARSCOTT.

Citrus Medica var. Limonum. We saw recently some very fine fruits of this in the temperate house at Kew. They measured about 9 inches in length and about 18 inches in girth.

INDOOR GARDEN.

ACALYPHA HISPIDA.

VERY large plants of this are handsome, but it is not everyone who has the conveniences for growing them. Probably the most useful plants are those with a single stem and clothed with leaves down to the pot. This plant appears to have no particular season for flowering, and may be had at any time by striking successional batches of cuttings. As the older plants begin to get leggy the tops should be taken off, inserted singly in small pots, and plunged in bottom heat. If placed under bell-glasses or hand-lights in the propagating pit they root very quickly; indeed, I know of scarcely any other plant which so soon fills its pots with roots, consequently they soon want re-potting and this must be repeated before they get pot-bound, so that they may be kept moving. The soil used should be rich and contain a good proportion of loam. I find that this plant does best in a stove temperature, but the atmosphere should be moderately dry to keep the ornamental tassels in beauty, as damp quickly spoils them. When stock has to be increased one has to resort to side cuttings from beheaded plants, but these do not make good plants right away, and should only be grown long enough to admit of good leading cuttings being obtained from their tops in turn. T.

EUPHORBIA JACQUINLEFLORA AS A CONSERVATORY PLANT.

A NOTE lately appeared on the above striking plant, which in mid-winter provides its brilliant flower racemes, absolutely unique at that season of the year in their vivid orange-scarlet colour. The writer of the note in question recommends entire stove culture, and doubtless such a course is more

7 feet in width from the back wall to the front lights. Two French windows opened from the living-room into the conservatory, and a gentle heat was kept up in the pipes; but on the frosty day of my visit the thermometer was as low as 55°, a heat amply sufficient for the Chrysanthemums, which formed the chief feature of the conservatory, but one would have imagined utterly inadequate for the Euphorbia. The plant, however, was flowering freely and appeared in the best of health. It was growing in a border and covered many feet of the wall, and, I was informed, had blossomed satisfactorily for some seasons. The locality was South Devon, and the exposure of that portion of the conservatory which contained the Euphorbia, and which, doubtless, became intensely hot in the summer months, was due south. Possibly the ripening of the wood, induced by the summer roasting, may have enabled the plant to withstand with equanimity the exceptionally low winter temperature to which it was subjected. Be that as it may, the instance quoted proves the possibility, if not the advisability, of growing and flowering Euphorbia jacquiniiflora in a comparatively low temperature. F.

APHELANDRA NITENS.

Of the numerous bright-coloured Acanthiads that bloom during the winter months this is one of the most brilliant, while the foliage is also ornamental. The individual leaves, which are about 6 inches long and 3 inches wide, are of a deep purple underneath, but on the upper part the colour is a rich bronze which shines as if varnished. The flowers spring from the axils of large adpressed bracts, which form a four-sided spike about 6 inches in length. Their colour is bright scarlet. They do not last very long, but as a succession is kept up for some time from one spike, the flowering season of this Aphelandra extends over a lengthened period. It is a native of New Grenada, and was discovered by Pearce of

of bright orange-red flowers. There is a white-flowered variety alba but plants of this usually show a tendency to revert to the normal form either in the shape of entire blossoms of a red hue, or stripes and flakes of that tint on a white ground. A nearly-related Azalea also in bloom at the present time is *A. calyciflora*, in which the blossoms are of a hose-in-hose conformation, as in the better-known *A. amena*. Their colour is, however, much the same as that of *A. obtusa*. This last is quite an old plant in gardens, yet it received an award of merit from the Royal Horticultural Society as recently as 1898. Though so generally known as Azaleas, all of the above, according to the latest botanical authorities, are now included in the genus *Rhododendron*, that at the heading of this note being *R. indicum obtusum*. T.

EXPERIMENTAL PLANTING.

NO HARD-AND-FAST RULES CAN BE FOLLOWED.

ALTHOUGH in the cultural directions given for various subjects the conditions advocated are those that long experience has proved to be most congenial to their requirements, all lovers and intimates of the garden are able to recall instances in which, under apparently the most adverse circumstances, shrubs and plants have exhibited a vigour that certainly was not to be anticipated in view of the nature of their surroundings. Bearing this fact in mind, the experimental planter who finds himself unable to afford either in a greater or less degree the ideal conditions for some particular subject, should not thereby be deterred from giving it a trial, which, if it be followed by success, will be all the more gratifying on account of the uncertainty attending the result, while, should it prove a failure, the substitution of some plant that has evidenced its adaptability to the immediate environment is easily effected. In advancing the foregoing proposition the last thing in the writer's mind is to advocate a disregard of the justly accepted methods of culture which have, during years of exhaustive trials, proved conclusively that, by implicitly following their details, perfection is more easily attainable than by any other procedure. As far as possible the time-honoured rules as regards soil, situation, and exposure should be followed; but in the same garden the varied accepted requirements of diverse families of plants can be supplied only by the expenditure of considerable labour and money, and in many cases, owing to the configuration of the ground, absence of water, or some other insurmountable difficulty, are impossible of attainment. It is under such circumstances that the experimental planting of subjects in situations and soils held to be inimical to their well-being is worthy of a trial.

Experientia doct is a motto that, although its wording allows its application to experience gained through another, is generally inferred to apply to personal experience, and this is the kind of experience that is particularly valuable in the garden. Plants that succeed in one garden are often found to fail in another where the conditions are apparently precisely similar, while vigorous health is sometimes exhibited under circumstances that would appear to favour premature decease or debilitation.

One of the finest specimens of *Spiraea arifolia* that I have met with is growing on a steep slope of shallow, shaly soil in a southern exposure. During the whole of the summer the soil is practically dust-dry except after rain, which percolates through it immediately, yet this shrubby Meadow Sweet is in as rude health as if it were situated by the waterside, and invariably blooms profusely and makes good growth. In the same garden is a fine plant of *Spiraea flagelliformis*, whose condition is equally satisfactory. To anyone conversant with the needs of the *Spiraeas* the garden in question would appear to be as disadvantageous a site as could well be selected for their culture, yet their behaviour leaves nothing to be desired. Possibly their roots may have got down to a layer of rock, over which some moisture is continually finding its way, but this is mere conjecture.

NARCISSUS CYCLAMINEUS AT WARLEY PLACE.

likely than any other to be followed by satisfactory results. It is, however, a mistake to infer that because a stove temperature is to be preferred for this subject it is useless to attempt its culture in a cooler structure, since it may occasionally be found doing well under far cooler conditions. An instance of this came under my notice a few weeks ago, when I saw a large specimen in full bloom on the back wall of a conservatory that followed an angle of the dwelling-house, the portion in which the Euphorbia was growing being only about

tuberous Begonia fame when travelling for Messrs. Veitch, with whom it first flowered in 1868. Like its allies, this Aphelandra succeeds with ordinary stove or warm greenhouse treatment. H. P.

AZALEA OBTUSA.

This pretty little Japanese Azalea can without difficulty be had in flower by Christmas, at which time it is valuable for the greenhouse. It forms a freely-branched, compact bush with a profusion

TROPEOLUM SPECTOSUM AND T. TUBEROSUM.

In another garden that I am acquainted with, which contains a large collection of rare and beautiful plants, *Tropeolum speciosum* was planted in many positions, care being taken to afford a porous root-run and a sufficiency of shade, for in the south it is almost impossible to establish this *Tropeolum* in a situation exposed to the full rays of the sun. After the planting was concluded a certain quantity of roots remained over, and these were placed in holes dug at the foot of a spreading young Yew tree, the soil not being disturbed further than was necessary for covering the roots. After this was effected, these latter were not given another thought, as they were not expected to succeed, and had only been roughly planted as an alternative to being thrown away. In course of time all the carefully planted and tended *Tropeolums* disappeared, and for a couple of years the forgotten roots beneath the Yew did nothing to advertise their existence. In the third year, however, a vivid splash of vermilion on one of the branches of the Yew drew attention to the fact that the plants were not only alive, but in the best of health, in which state they have since remained, garlanding the sombre foliage during the summer months with an opulence of colour that year by year increases in extent. In the same garden *Tropeolum polyphyllum*, contrary to its usual custom, blossoms as freely in partially shaded spots as it does in open positions exposed to every ray of sunlight.

The handsome *Tropeolum tuberosum* is a somewhat erratic subject as regards its blossoming, apparently flowering considerably earlier in the south-east of England than the south-west. In Sussex I have seen it in good bloom in the second week of July, in Dorsetshire a cloud of orange and scarlet early in August, but in South Devon the majority of specimens that I have met with have rarely been in full flower before October, while in some cases their first blooms have not expanded until November, and in others they have shown no signs of flower. All the instances to which I allude were of plants grown on open walls in sunny situations. In one case in the same locality I saw a specimen in flower during the early part of September, but this was growing in light soil and had but a very restricted root-run.

Montbretias and Tigridias are generally supposed to flourish best in a comparatively dry rather than a damp site, yet the finest specimens of these plants that have come under my notice were growing by the side of a sheet of ornamental water. In the case of the Montbretias the corms were on the level of the water and the plants showed surprising vigour, their leaves being exceptionally long and almost as broad as those of *Gladiolus brechenleyensis*, while they were bearing a profusion of fine flower-scapes. The Tigridias, which were growing on a slightly higher level, were carrying immense blossoms on stems 2 feet and more in height. *Lobelia fulgens* in heavy, damp soils is a hardy perennial, requiring not the slightest winter protection in localities as far distant as Suffolk and South Devon, but in light soil in the latter district I have found it impossible of preservation through the winter even when mulched with leaf-mould, yet I have often seen a porous, friable compost recommended for this subject in preference to one that is of a damp and heavy nature. *Zauschneria californica* and *Plumbago Larpentæ* have grown and flowered well with me in South Devon in retentive loam without the slightest lightening of the staple, the latter plant spreading rampantly and blooming profusely close to the edge of a streamlet. In the same heavy soil I have seen a large patch of *Onosma tauricum* in a flat bed the picture of robust health and bearing hundreds of pendent yellow blossoms, and during the past summer a colony of *Edelweiss* (*Gnaphalium leontopodium*), growing in a slightly sloping bed of the same heavy red loam, was a mass of plush-like white blossom, yet, where other composts were easily available, such a staple would scarcely be selected for the culture of any of the four plants last named. *Campanula pyramidalis* is a subject whose culture, when it is not used as a pot plant, is practically confined to the herbaceous border, but during the past autumn I saw three fine specimens, each carrying a dozen or so flower-

spikes, growing in the interstices of a retaining wall. These plants had sprung from self-sown seeds, and presented a very striking and decorative effect.

Even after the unprecedented drought of the summer, and though growing in a sun-baked situation, the plants in question showed no signs of flagging, their roots having evidently penetrated deeply into the soil at the back of the wall.

This chance instance points to the advisability of making experimental sowings of the seed of stronger-growing subjects than are generally met with in the wall garden in the spaces between the stones, since, should the issue be successful, the diversity of form obtained will add considerably to the charm of the flower-mantled wall. Some shrubs that are almost invariably trained against walls, such as *Pyrus* (*Cydonia*) *japonica*, are very attractive when grown in bush form. This *Pyrus* flowers freely when thus treated, although it is naturally rather later in coming into bloom than in cases where it receives the protection of a wall. Fruit is often produced on bush as well as on wall plants, and a few years ago I saw in the south of Ireland a large specimen some 8 feet high and as much through that was bearing a large quantity of well-developed fruit. *Pyrus japonica* is a hardy subject that will grow in almost any soil or position, and is very tenacious of life. Seven years ago a rocky mound 15 feet in height on which a bush was growing was quarried away to make room for a building, and the shrub, which was of considerable size, transplanted to another part of the garden towards the end of May. The roots, which descended deeply into the rock, were unavoidably damaged in the lifting, but in spite of this, the untimely planting season, and a hot summer, the vitality of the shrub pulled it through. A portion of the roots of this shrub was evidently left in the rock, for during the following spring a tiny green shoot appeared about 5 feet from the summit of the perpendicular rock wall. This increased in size rapidly, and has now developed into a bush, issuing from the solid cliff, with branches over 3 feet in length.

The Winter Sweet (*Chimonanthus fragrans*), generally grown against a wall, does well as a bush in the open in the south-west, and is now bearing its sweetly perfumed blossoms. In places where sufficient space is not available for standard flowering trees, these may be grown against a wall, though the natural grace of contour is unavoidably lost by this method of culture. No comparison exists between a *Laburnum* with spreading branches growing in unrestrained freedom, laden with drooping golden flower-clusters, and the same subject stilly trained to a wall, a system which, indeed, is rarely followed. Only one instance of this use of the *Laburnum* has come under my notice, this having happened a few springs ago, when, seeing a distant house wall clothed in glowing yellow, I made a closer inspection, and found the whole side wall of the end house of a row covered with the blossoms of a closely-trained *Laburnum*. The road was but 6 feet distant from the wall and the tiny front plot, bisected by a path, afforded no room for a standard specimen, so that the proprietor, possibly an enthusiast in the matter of *Laburnums*, had, if he grew the tree at all, to avail himself of the only space at his disposal—in his case a justifiable experiment. S. W. FITZHERBERT.

CHRYSANTHEMUMS IN VASES.

Few will object to the discontinuance of exhibiting cut *Chrysanthemums* on green-painted boards, which has, in the opinion of many, become monotonous, and I think rightly so. We are certainly indebted to our northern friends at Edinburgh for launching out as they did a few years since by offering valuable prizes for vases of cut *Chrysanthemums*. Many had misgivings about it, the principal objection being the doubt as to whether they would last in a fresh condition to the close of the exhibition. All doubts as to this and other objections were dispelled; each year more and more interest has centred in these classes, and the contest has been of the keenest description. The National *Chrysanthemum* Society did well to

follow this example, and by offering such handsome prizes as they were able to do last November, brought together, without doubt, the finest collection of cut *Chrysanthemums* ever seen. Nevertheless, in my opinion, and in that of many others, this style of exhibiting may yet be vastly improved upon; for, as one of our leading authorities justly wrote in the Press a short time ago, have we not exchanged one monotony for another? Each exhibitor might be allotted a given space, each using the same kind of vase, which should be provided by the society, and, of course, stipulating the number of blooms to be used in each vase. He might be allowed to use what natural foliage he chose, and also a groundwork of Ferns or any other small-growing foliaged plants in pots.

I should also like to see a class introduced of, say, twelve or eighteen vases of any large-flowering kinds, including, if thought well by the exhibitor, Japanese, incurved, reflexed, and large *Anemones*. Good judges would be able to determine the relative value of each, and I feel sure such a class would attract much attention. I know many argue that incurved *Chrysanthemums* do not lend themselves to this style of exhibiting, but some of the best vases I have seen have been those of incurved Japanese, and I am perfectly convinced that many of our best incurved varieties could be arranged equally well.

Pompon and pompon *Anemone* varieties should also, I am sure, be encouraged in the same way. This charming section would then be seen in their full beauty. Who, indeed, could have failed to have been struck by the two fine exhibits shown by Messrs. Davis and Jones, both in London and Edinburgh, not so much by the individual blooms as by the charming arrangement made by each?

E. BECKETT.

Abraham House Gardens, Elstree, Herts.

Senecio macroglossus. This is a pretty greenhouse climber with thick, shining, ivy-like leaves. It is in flower at the present time, its large yellow flower-heads being similar to those of the *Marguerite*. It is very useful and welcome at this time.

Antholyza æthiopica minor. Some pots of this South African bulbous plant in the T range at Kew each contain a number of flower-spikes, and form just now an attractive feature. In general appearance the plant bears a considerable resemblance to some of the garden varieties of *Montbretia*, but the foliage is rather wider and of a richer green. The colour of the flowers is brilliant orange-red, with darker markings at the entrance to the throat. Though it is named as above at Kew in their hand list of monocotyledons, the variety *minor* is referred to *bicolor*. A group of half a dozen pots or so of this *Antholyza* would form an attractive feature for the greenhouse at this season, when the *Montbretias* are all at rest.

The Flame Nasturtium (*TROPEOLUM TUBEROSUM*) in Devonshire. Several notes have appeared of late on this *Tropeolum*, in one of which Mr. S. A. Arnott asks if the tubers are hardy in Devonshire. The plan generally adopted is to lift these in the winter after the foliage has withered as described by Mr. James Day (page 389), as in hard winters the tubers often are frost-bitten, but after mild winters it is not at all unusual to find young plants springing up from tubers that have been overlooked. The tubers increase at a great rate, and I have known as many as fifty dug up from the roots of a single plant. In some districts of South Devon this plant is late in coming into flower, in many cases not attaining the zenith of its beauty until mid-October, and retaining its blossoms throughout the entire month of November should the weather be mild. Mr. Arnott mentions that an addition of lime to the soil is held to induce floriferousness. I have, however, grown it in a light, shaly soil which contained a considerable proportion of lime without hastening its blossoming, although the situation was exceptionally warm and sheltered and apparently favourable to early maturation. S. W. F.

AN ARTIST'S NOTE-BOOK.

PHALANOPSIS SANDERIANA AND ITS VARIETIES.

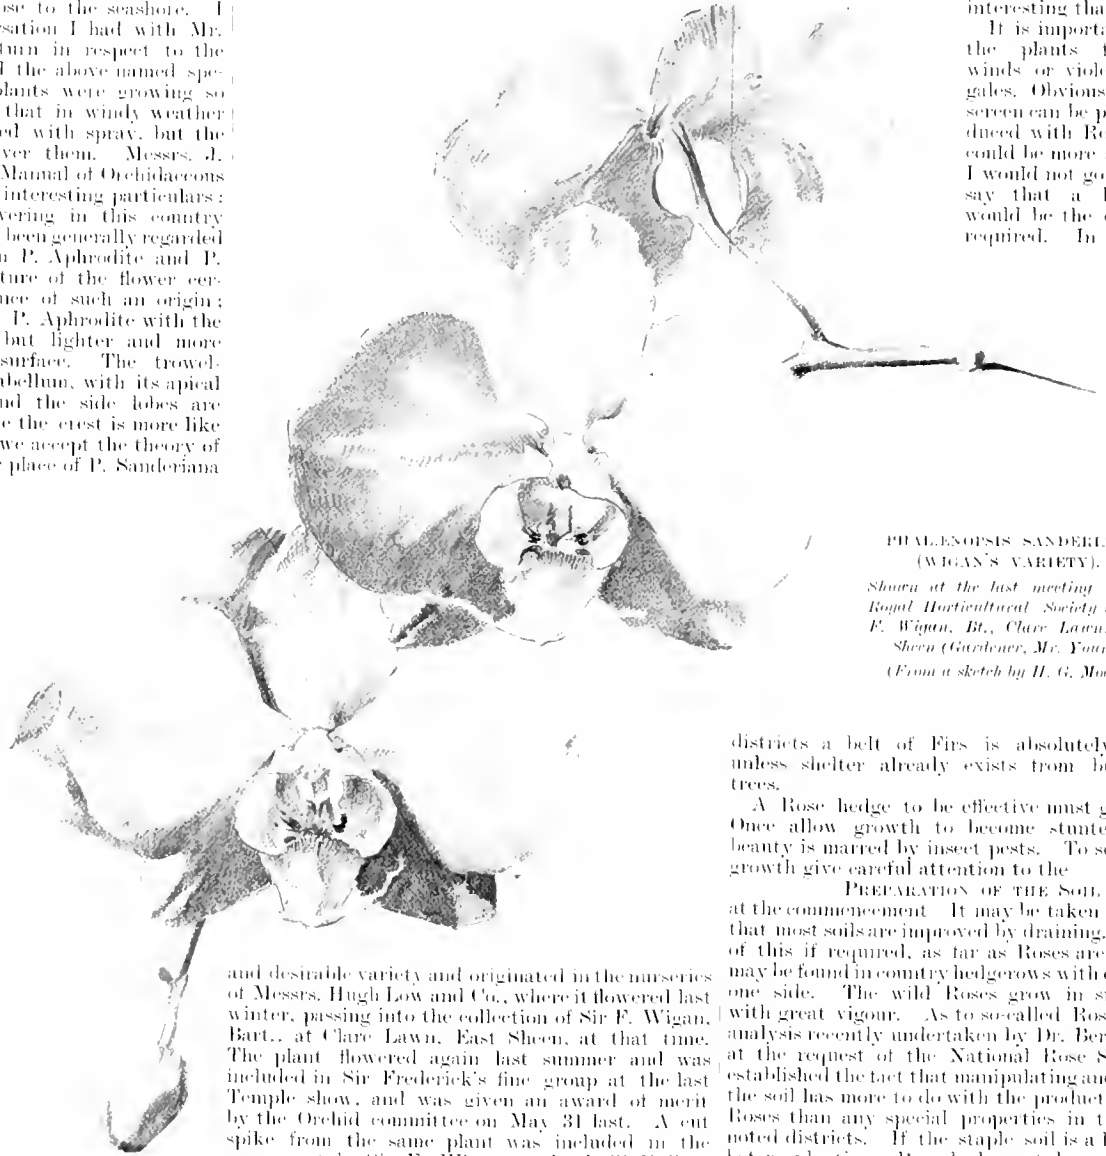

PHALANOPSIS SANDERIANA was introduced to European gardens in 1828 by Messrs. F. Sander and Co. from the Philippine Islands. Almost immediately afterwards, the late David Bark, collecting for Messrs. J. Veitch and Sons, found it in the neighbourhood of Davao, on the south east coast of Mindanao, associated with such lovely species as *Vanda Sanderiana* and *Aerides Lawrenceae*. It has also been detected on the small island of Serangan, growing on trees close to the seashore. I can call to mind a conversation I had with Mr. Bark shortly after his return in respect to the situation in which he found the above named species. He said that the plants were growing so close to the water's edge, that in windy weather not only were they drenched with spray, but the waves frequently broke over them. Messrs. J. Veitch and Sons, in their "Manual of Orchidaceous Plants," give the following interesting particulars: "Ever since its first flowering in this country *Phalanopsis Sanderiana* has been generally regarded as a natural hybrid between *P. Aphrodite* and *P. Schilleriana*, and the structure of the flower certainly affords strong evidence of such an origin; it has the general aspect of *P. Aphrodite* with the colour of *P. Schilleriana*, but lighter and more diffused over the whole surface. The trowel-shaped front lobe of the labellum, with its apical tendril-like appendages, and the side lobes are those of *P. Aphrodite*, while the crest is more like that of *P. Schilleriana*. If we accept the theory of its hybrid origin, the proper place of *P. Sanderiana* would be in the group of natural hybrids of which *P. leucorhoda* is the type, and which bears unmistakable marks of being derived from the same pair of species. Nevertheless, there are other circumstances attending the environment of *P. Sanderiana* that must not be overlooked, of which the most prominent are these: It has been brought from a locality remote from the habitat of the supposed parents, of whose presence in that locality no evidence is forthcoming; it has been imported unmixed in considerable numbers, and not, as in the case of un doubted hybrids, as isolated plants, whose appearance among the assumed parents is comparatively a rare occurrence. On these grounds, therefore, we recognise *P. Sanderiana* as a species in the ordinary acceptation of the term; but whether species or hybrid, it is without question one of the most beautiful of the section to which it belongs." The leaves of *P. Sanderiana* vary in colour, sometimes resembling those of *P. Schilleriana*, whilst others are covered with a beautiful silvery grey suffusion, and some may be found almost identical with those of *P. Aphrodite*, being wholly of a deep green. All this suggests that *P. Sanderiana* may be a natural hybrid. Can it therefore be possible that in these isolated positions *P. Sanderiana* is the offspring of some previous species now extinct?

The typical forms of *Phalanopsis Sanderiana* have flowers about 3 inches in diameter, the upper sepal light rose-pink, the lateral sepals much paler in colour, almost white. The petals are rather darker

in colour than the upper sepal. The front lobe of the lip has two curved tendrils, white, with some tracings of rose at the base; the side lobes white with some yellow at the base, where there are a few small longitudinal streaks of purple.

P. S. alba has pure white flowers, except the yellow crest and a few purple streaks at the base of the side lobes. It might be mistaken for a variety of *P. Aphrodite*, but the foliage is suffused with a distinct silvery-grey suffusion.

P. S. (Wigan's variety). The subject of the accompanying illustration is by far the deepest coloured variety that has been seen. The intense lilac suffusion of the sepals and petals is in striking contrast to the almost white lip. It is a charming

PHALANOPSIS SANDERIANA
(WIGAN'S VARIETY).

Shown at the last meeting of the Royal Horticultural Society by Sir F. Wigan, Bt., Clare Lawn, East Sheen (Gardener, Mr. Young).
(From a sketch by H. G. Moon.)

and desirable variety and originated in the nurseries of Messrs. Hugh Low and Co., where it flowered last winter, passing into the collection of Sir F. Wigan, Bart., at Clare Lawn, East Sheen, at that time. The plant flowered again last summer and was included in Sir Frederick's fine group at the last Temple show, and was given an award of merit by the Orchid committee on May 31 last. A cut spike from the same plant was included in the group sent by Sir F. Wigan to the Drill Hall on January 9 last, from which the illustration has been produced.

P. S. intermedia is a distinct form, having spots along the lower sepals similar to those frequently seen in *P. Aphrodite*, the side lobes of the lip being also marbled with purple.

P. S. punctata is a pale form with deeply tessellated foliage; the flowers pale in colour, and the lower sepals thickly covered with spots like those of *P. Stuartiana*.

H. J. CHAPMAN.

A NEW SNOWDROP.

GALANTHUS ELWESI VAR. WHITTALLII.

This is a valuable introduction by Mr. Edward Whittall, of Smyrna. It grows taller than the well-known *Galanthus Elwesi*, is of more robust habit

and with much broader foliage; in fact, the latter character is very marked. The flowers vary, but are inclined to develop to a large size, some eclipsing all other Snowdrops in this respect. Last year in the Kew Gardens some of the flowers were of extraordinary size. As our illustration shows, the flower is of elegant globular form, while the tube more than half way from the base is of a bright green colour and lightly tipped with the same shade. Altogether *Galanthus Elwesi* var. *Whittallii* promises to be the finest Snowdrop yet introduced.

MAKING ROSE HEDGES.

PERHAPS of all the shrubs employed for hedge-making none are more interesting than Roses.

It is important to screen the plants from north winds or violent westerly gales. Obviously, if such a screen can be partially produced with Roses, nothing could be more appropriate. I would not go so far as to say that a Rose hedge would be the only shelter required. In cold, bleak

districts a belt of Firs is absolutely necessary unless shelter already exists from buildings or trees.

A Rose hedge to be effective must grow freely. Once allow growth to become stunted, then its beauty is marred by insect pests. To secure a free growth give careful attention to the

PREPARATION OF THE SOIL.

at the commencement. It may be taken for granted that most soils are improved by draining. Evidence of this if required, as far as Roses are concerned, may be found in country hedgerows with dykes upon one side. The wild Roses grow in such hedges with great vigour. As to so-called Rose soils, the analysis recently undertaken by Dr. Bernard Dyer, at the request of the National Rose Society, has established the fact that manipulating and manuring the soil has more to do with the production of good Roses than any special properties in the soils of noted districts. If the staple soil is a heavy clay, before planting a Rose hedge put down some drain pipes about 2 feet 6 inches deep. If a clayey loam, then about 3 feet. The ground should be trenched two spits deep for the heavy soils and bastard trenched for those of a lighter nature. Good, well-decayed farmyard manure, together with burnt garden refuse and bone-meal, all favour a vigorous growth in the hedge.

Rather than make the soil sour by too much raw manure, I would advise the liberal application of liquid manure, not only in summer, when growth is active, but also during winter, when usually this valuable liquid runs to waste.

The ground being prepared (and the earlier this is done the better) the question arises

HOW AND WHAT TO PLANT.

Most of the kinds I shall recommend will, in time, support themselves; but, if a tall hedge be desired,

I would advise that some oak posts be set in the ground at intervals of about 6 feet to 8 feet to support two or three lengths of wire. Do not use galvanised wire unless painted. These posts and wires are quickly hidden. Although not absolutely necessary they are a great support against violent gales, and also enable the branches to be spread out.

Crowded planting should be avoided. Give the plants space to extend laterally, then vigorous growth may be secured from the base, and this is essential.

PRUNING.

Rose hedges must be pruned to promote free flowering. How this should be done must largely depend upon the variety. I am no advocate for the trim Rose hedge. I like to see the flower-laden branches drooping with their weight of blossom.

It must be remembered that in dealing with Roses the one and two-year-old growths produce the best flowers, but pruning requires judgment. Some Roses produce healthy laterals from three and four-year-old wood, but one or two of these old branches can well be spared from each plant, and their removal affords to those remaining the benefit of more air and light.

With the majority of Rose hedges the necessary pruning may be wholly or partially done in autumn, to the evident benefit of the plants.

As to the style of plant, where strong own-root Roses cannot be had, then obtain them on the Briar—the seedling for preference—for its roots are so penetrating that they not only are able to withstand drought better, but growth is so much encouraged. Now as to the

VARIETIES TO PLANT.

I have seen what one might term a wall of Roses rising 8 feet to 10 feet high consisting of varieties of *Rosa sempervirens* and the *Ayrshires* (*R. arvensis*).

If a support of some kind be given, these classes are admirably adapted for the purpose. One or two kinds, such as *Félicité-Perpétue*, are almost evergreen.

Crimson Rambler makes a splendid hedge, and, for effectiveness, remains unrivalled; but there are many who cannot endure its garish colouring. This could be toned down by intermingling a white variety, such as *Aimée Vibert* or *Félicité-Perpétue*. A softer tint is found in the rosy-pink Dawson Rose, and it has the additional and valuable quality of fragrance.

How lovely are hedges of the Penzance Sweet Briars! They are now largely employed for this purpose. The exquisitely tinted blossoms are not long with us, but they come very early, and the fragrant foliage remains, followed by the showy fruit. When planting hedges of these Briars I would not advise too many kinds—in fact, one kind only would be best. The best for the purpose are *Annie of Gierstein* or *Meg Merrilies*, crimson; *Amy Robart*, pink-white, has also the finest fruit; and *Lady Penzance* the most charming of all, with coppery-yellow flowers, but rather less vigorous in growth. Of course we must not forget the old

SWEET BRIAR.

which has done duty for hedges so long; but the hybrids are freer and the foliage is almost as aromatic.

There are quite a number of single Roses suitable for hedges, but the flowers of many are not interesting.

Some of them are meritorious on account of their coloured bark in winter. Of these, *R. villosa rubrifolia*, *R. lucida*, *R. polyantha Thunbergii* may be mentioned.

Carmine Pillar is also a capital single Rose for hedges.

If one is seeking for a Rose hedge that is almost evergreen, the best kinds are *Longworth Rambler*, *Aimée Vibert*, *Félicité-Perpétue*, *Reine Olga de Wurtemberg*, *Marie Lavalée*, and *Climbing Souvenir de Wootton*.

The numerous *Rugosa* tribe for vigour and hardness are unsurpassed. They are prone to become bare at the base, but the pruning advised above would remedy this. When growing freely and covered with the glowing fruit they are indeed a beautiful sight.

An excellent Rose to make a hedge is of

R. multiflora de la Grifferaie. It yields large trusses of blossom, somewhat in the way of *Crimson Rambler*, but the colour is rosy-pink, and some flowers change to nearly white when expanding.

Fairly high hedges may be formed with *R. alba Celestial*, *R. gallica Rosa Mundi*, the Austrian Briar *Harrisonii*, or the single *R. lutea*.

Rose-growers are looking forward to the promised novelty of that eminent raiser, M. Pernet-Ducher. He describes it as a new race, being the outcome of a cross between *Persian Yellow* and the *H.P. Antoine Ducher*. It partakes much of the character of *Persian Yellow*, excepting that it is perpetual. It should prove a valuable hedge plant.

GALANTHUS ELWESI VAR. WHITTALLII.

(From a sketch by H. G. Moon.)

The Hybrid Chinese and Hybrid Perpetuals make good hedges. They are of somewhat stiff growth. Of the former, *Charles Lawson*, *Coupe d'Hebe* are the best; and of the latter, *Ulrich Brunner*, *Magna Charta*, *John Hopper*, *Crimson Queen*, *Cho*, *General Jacqueminot*, and *Mrs. John Laing* might be mentioned.

It may be that a hedge is desired that not grow too tall, one—for example—to surround the tennis lawn or to divide the flower garden. For this purpose nothing can be more beautiful than the Monthly Roses. Where a finer flower be preferred for the same object choose the *Teas* and Hybrid *Teas*, *Madame Abel Chatenay*, *Caroline Testout*,

Grace Darling, *Viscountess Folkestone*, *Marie van Houtte*, *Saturno*, *Gruss au Teplitz*, *Eucharistoss*, *Mme. Lombard*, and *Grace Darling* all make delightful hedges from 4 feet to 5 feet high.

A good dense hedge can be made with the early flowering Scotch Roses, not forgetting the single varieties of the same tribe. Not so dense as a plant but very beautiful is the *Stanwell Perpetual Scotch*, flowering as it does nearly all the season. I should like to see a hardy race of single *Teas* raised for making hedges.

PULLOVEL.

ERANTHEMUM NERVOSUM.

The brilliant blue flowers of this *Eranthemum*, produced as they are during the dull days of winter, are admired by everyone, and its value as a decorative plant is still further enhanced by the fact that it is of easy culture. Cuttings struck in early spring will form effective bushy specimens by the autumn. If grown on freely they will require pots from 6 inches to 8 inches in diameter. During their earlier stages the plants should be grown near the glass in a stove temperature, but in summer they may be removed to a frame. Liquid manure is of considerable service as the pots get full of roots. The principal consideration is to prevent the foliage from becoming infested with red spider, as it is rather liable to the attacks of this pest. A fairly moist atmosphere with occasional syringing, directed as far as possible towards the undersides of the leaves, will keep them in good condition. Besides the above-mentioned name this *Eranthemum* is often met with under the specific name of *pulehellum*. It is a native of the lower portions of the Himalayas, and is an old plant in gardens, having been introduced in 1796.

T.

Dædalacanthus macrophyllus.

This is nearly related to the *Eranthemum*, and the entire plant when out of bloom bears a considerable resemblance to the charming *E. nervosum*, but the flowers are altogether different. In the *Dædalacanthus* the individual flowers are about 1½ inches long, curved in shape, and of a purplish mauve tint, the lower lobes being of a deeper hue. They are disposed in a terminal pyramid-shaped branching raceme. It is most satisfactory when propagated from cuttings every spring and grown on freely for flowering during the following winter. — H. P.

Acacia dealbata. This, the Silver Wattle of Australia, is a grand subject for lofty structures, but for an ordinary greenhouse it grows too tall, being in fact quite a tree. The finely-cut leaves of almost silvery whiteness are very attractive, but in this respect there is a good deal of individual variation. This mass of Fern-like foliage serves admirably as a setting for the racemes of bright yellow blossoms. In the neighbourhood of London it is very liable to injury from the dense sulphur-laden fogs which have been prevalent this winter. As a foliage plant out of doors during the summer months this *Acacia* is of considerable merit, while along the Mediterranean shores it is one of the most beautiful of flowering trees. As above noted, the silvery character of the foliage varies, and seedlings raised from a particularly good form were in some instances nearly green, not more than 10 per cent. being equal to the parent. T.

Coronilla glauca. Prior to *Cytisus racemosus* attaining its present popularity, this *Coronilla* was grown more than it is now-a-days. There is, however, ample room in most gardens for both, as they are in all respects quite different from each other, and whereas the *Coronilla*, generally speaking, flowers during the autumn and winter, the other is at its best in spring and summer. The glaucous green foliage of the *Coronilla* is very pretty, while the clear yellow flowers are borne in small rounded clusters. It is more particular in cultural requirements than the *Cytisus*, and quickly resents too much water at the roots, while at the same time it should not be allowed to become too dry. The *Coronilla* is a native of the south of Europe, and was introduced as long ago as 1722. It is readily increased by cuttings of the short jointed shoots put into sandy soil and kept moderately close till rooted. — H. P.

FERNS.

UNIQUE BRITISH FERNS.

ALTHOUGH there is no doubt whatever that all existent species of Ferns are apt to vary, not merely to that small degree which enables the selective cultivator gradually to improve or emphasise the type by judicious choice of seedlings, but also in that markedly distinct way which constitutes "sports," it is a remarkable fact that amongst our comparatively few British species abnormalities have arisen which have no parallels at all in exotics.

In the cultivator's hands other varieties have arisen which also so far transcend the parental abnormal type, as to be also unique in their way. Among the wild finds of the unique class the

POLYSTICHUM ANGULARE VAR. PLUMOSUM DENSUM.

1. The normal form of species. 2. Wild find in South Devon. 3. Frond of densum raised from 2. 4. Pinna of imbricatum raised from bulbil of densum.

Victoria Lady Fern undoubtedly ranks first and foremost among the abnormal Ferns of the world, though, thanks to its fertility and constancy to type, it has long ceased to be rare in collections. The common Lady Fern, as every plant lover knows, is a robust growing plant with large feathery fronds of delicate texture, consisting of a central stalk decked on either side with feathery divisions, once or twice divided on a sort of vegetative crystalline plan, forming a whole of great beauty, the fronds attaining 3 feet to 4 feet in height and about a third of that in width. Such plants in congenial fern localities may be found in myriads, all on precisely the same plan, though apt to differ in detail of cutting.

In 1861, however, a Mr. Cosh, springing over a stone dyke near Loch Lomond, found at his feet a plant of this species constructed on an entirely different plan, each side division being extremely slender, and bearing a fine-cut tassel of many strands at its extremity, and, what is more wonderful, each such division was duplicated, the pair so joined being set on at about right angles to each

other, with the result that the frond, also narrowed to match, was made up of a series of symmetrical crosses, forming a lattice on each side of it, the frond finishing up with smaller and smaller crosses, merging into a handsome many-stranded tassel to match the side-ones. Finally, it was seen that even the small ultimate divisions were also in pairs, forming a really astounding and yet charming freak of Nature's own contriving. Extended and repeated search has failed to find a second specimen from that day to this, and no Fern so characterised has turned up elsewhere in any part of the world.

The spores being sown yield plants of precisely the same type, but while the original find has attained a frond length of 3½ feet in the writer's collection, no seedling grows nearly so large so far as we have been able to ascertain. Another Lady Fern (*Athyrium F. f. acrocladon*) found as a seedling on a Yorkshire moor has also no parallel in exotics, but as simply an extreme form of cristation, ramifying from the base into innumerable divisions until it resembles a ball of moss, it does not rank in uniqueness with the last named; one of its progeny, however (*A. F. f. uncoglomeratum*), so far exceeds it or any other Fern in this capacity of division as to stand alone as a curiosity. This is almost indescribable when well developed. A spherical mass of light green foliage, densely packed and comminuted to the utmost, surrounds an infinite ramification of branches, twigs, and hair-like twiglets, the whole resembling rather a green coralline sponge than a Fern or any other plant. This Fern is rendered still more noteworthy by the fact that its faculty for dividing and re-dividing outlives its annually deciduous character; and pieces cut off in the autumn and layered not only continue to grow, rotting below and growing above, Sphagnum fashion, but eventually produce bulbils and aposporous or prothallie growths by which the type is reproduced without the agency of spores. Here, again, there is absolutely no parallel, taking all the peculiarities together.

In *Scolopendrium crispum Drummondiae*, found wild by Miss Drummond, we have another Fern without a counterpart, and, as in the Victoria Lady Fern, owing nothing of its marvellous character to culture. In this the normal strap-shaped Hart's-tongue frond is lengthened out considerably and reduced in width. It terminates, as in many other Hart's-tongues, with a wide-spreading tassel; but its edges, instead of being smooth, grow out into long imbricated projections with translucent tips, and these, if layered, form prothalli and reproduce the type again without the agency of the spore. Finally, as a further distinguishing feature, the fronds do not grow straight, but bend up and down, switchback fashion, some three or four times in the course of their length. Where is there an exotic, wild or cultivated, presenting such a marvellous combination as this?

Space precludes description of many other varieties which are practically solitary in their peculiar ways, though devoid of the complication seen in the above; but we cannot conclude without reference to several identical types of variation which have appeared in more than one of our native species, and of which as yet no exotic examples have either reached us from abroad or arisen under cultivation. Such, for instance, are the "revolvens" forms, in which the frond and all its parts are rolled backward into tubes, which are correlated with spiral or ringlet-like terminals, due to the adjustment of the upper surfaces to catch the light despite the twist. Of this we have well-marked examples in *Lastrea pseudo-nana*, or the Hard Male Fern; in *Polystichum angulare*, or the soft Shield Fern (see illustration); *Athyrium Filix-femina*, or the Lady Fern; and also in *Lastrea montana*, the Mountain Buckler Fern. In the Lady Fern the character is so marked, that the first frondlet from the prothallus is tightly curled up. Here we have four species out of only forty odd presenting the same abnormal character under wild conditions, while the thousands of exotic species have yielded, so far, no example; hence, to that extent they are unique. Our lovely plumose forms of Lady Fern, Shield Fern, Hart's-tongue, Moun-

tain Buckler Fern, *Blechnum Spicant*, common Polypody, *Asplenium marinum*, *A. Trichomanes*, and *Adiantum capillus-Veneris* embrace not single finds in each species, but many in most, and yet among exotics we can reckon the plumose forms upon our fingers. Hence, though we cannot claim the type as confined to our islands, we can certainly claim the cream of the varieties so characterised as against all the wide world beyond our shores.

CHAS. T. DRIFERY, F.L.S., V.M.H.

CORRESPONDENCE.

THE SWEET PEA CONFERENCE.

[TO THE EDITOR OF "THE GARDEN."]

SIR, The recent letters about this proposed conference should help to cut short any further attempts to raise a large sum of money to spend upon "social observances," prizes, and so forth. To make the Sweet Pea, a simple, beautiful garden flower, the subject of a conference is too bad. One may as well get up a conference with a dinner in honour of the fragrant giant Violet. No one can deny that many varieties are so much alike, that to distinguish one from the other is not easy even to the eye practised in making a variety whenever possible. The work of eliminating synonyms can be faithfully carried out by the Royal Horticultural Society; in truth, this making of "trials" is one of the most important phases of its work. ALPHA.

DEEP CULTIVATION AND ITS BENEFITS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, The advice laid down on p. 32 of THE GARDEN I may say is much too brief, and likely to mislead the novice. I would strongly advise anyone to well consider future results before burying a good top spit 3 feet deep, and replacing it with almost pure sand or clay to be the future top spit for immediate cultivation. Here should come the most important details on the treatment of this hungry surface upon which nothing is said. Surely there must be some mistake. I may say I know what it is to drain and burn clayey subsoil by the acre, but I should be very sorry to advise a novice to treat a plot as stated on page 32 by Mr. E. Bickett. Perhaps the writer will kindly say how he converts his nearly pure sandy and clayey surface into condition for sowing, &c. I personally know that it takes nearly a lifetime to render clay into anything like a suitable surface for general garden crops. JAS. R. HALL.

For Warren, Cobham, Surrey.

THE PROTECTION OF TEA ROSES FROM FROST.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Just as a good many of us, north and south, have reached the conclusion that Tea Roses are about as hardy as any other, we have the very able co-secretary of the National Rose Society, Mr. Edward Mawley, of Rosebank, Berkhamsted, Herts, writing in the first number of the new series of THE GARDEN on this subject.

It may readily be admitted that Mr. Mawley is perhaps our highest authority on Rose weather as well as Roses in general. Nevertheless, probably his meteorological training has given him a list toward the tender side of Roses which even his successful practice and the favourable soil and environment of Herts have hardly enabled him to overcome. Otherwise one can hardly understand the extreme brevity of his list of hardy Roses (p. 12). The old Cabbage or Provence, Moss, Scotch Rose, Stanwell Perpetual, the Ayrshire Briars—two of the pioneer Hybrid Perpetual Roses are still among the hardiest (Jules Margottin and Duchess of Sutherland), and let me add that Baron Prevost and General Jacqueminot are harder than either—some of the Rugosas, the Hybrid Sweet Briars, Crimson Rambler, and the Hybrid Tea Gustave Regis. Then

follows the sweeping assertion that among Rose most largely grown at the present day the Hybrid Perpetuals are undoubtedly the least tender. The general belief of rosarians in the year 1900 is that Teas are just as hardy as Hybrid Perpetuals, and neither more nor less tender, and if our co secretary of the National Rose Society, or rather our joint secretaries, will take a run north to the Rose nurseries at Aberdeen and Broughty Ferry, they will have such powerful demonstrations of the equal hardiness of Teas and Hybrid Perpetuals as shall convert them to the equal hardiness theory of most of our best Roses on the spot. Another lesson may also be learned in the north, viz., the uselessness or injury of most of our modes of protection. Perhaps an exception should be made in favour of Mr. George Paul's mode of increasing the temperature and the dryness of his root-runs the

Teas, and Hybrid Teas, and some of the latter, such as La France, are as hardy as the hardiest Hybrid Perpetual.

Among the hardiest Teas and Hybrid Teas or Noisettes are Mme. Lambert, Francisca Kruger, Anna Ollivier, Caroline Kuster, and the finest of all white Teas is Souvenir de S. A. Prince, while Sunset, Perle des Jardins, Mme. de Watteville, and Nphetos—the first three, perhaps without sufficient evidence—have been classed as more tender than the others.

A good deal of the popular judgment of rosarians may have been biased in regard to the smoothness or roughness of the bark of our Roses. From the introduction of the Pride of Waltham and other Roses, such as Countess of Oxford, Reynolds Hole, &c., it was thought and said by many that these were more tender than others with rougher bark, and

A MIXED BORDER AT DOWNSIDE, LEATHERHEAD.

A BEAUTIFUL feature of the gardens at Downside is the mixed border on the hill-top and dipping into the valley below, a mass of colour from the well-chosen hardy flowers distributed in broad groups. Mr. Alfred Tate has, perhaps, a stronger love for the Rose. We have never seen a more sumptuous display of the many classes than in the garden immediately near the house, and in the summer we hope to illustrate some of the richer beds of one variety, but show only at present the border, from whence the eye wanders over the Surrey hills and valleys, a land of tree and shrub, throwing into relief the colouring of the hardy flowers. The border is effective and happily placed, and in summer, when the Roses flood the garden with their perfume

PART OF THE MIXED BORDER ON THE HILLSIDE IN MR. ALFRED TATE'S GARDEN AT DOWNSIDE, LEATHERHEAD.

use of more or less highly raised beds. Overhead protectors, whether of straw, Yew or Spruce branches, or Braeken, and over-crown mulches of earth manure, litter, all entice the plants through coldling, and render them more liable to injury when they are uncovered. As for cotton matting and double or treble fish netting, they are worse than useless as protection from frost, either through creating a draught, whipping and bruising the Rose buds in embryo, or emasculating the natural hardiness of the Roses. Almost the only protective material worthy of a second thought is dry Braeken harvested in an unripe condition. A small handful of that thrust into the heads of standard perpetual, Tea, and Noisette Roses may do more good than evil when the thermometer gets on the cold track from 20 to zero Fahrenheit.

Beyond that all our best Roses are safer without covering or protection. Careful readers of Mr Mawley's article will see that he admits that there are degrees of hardiness even among Noisettes,

more protected by prickles, such as Marie Baumann, Mme. Gabriel Luizet, &c. Then the Teas having fewer prickles and smoother bark than Perpetuals, it might easily be assumed that they would be found equally tender.

Besides, the advance of science and practice have demonstrated beyond all controversy that the so-called hardiness and tenderness of plants may be more a matter of site, soil, stock, culture, season, than of constitution—that is, any natural hardiness or tenderness of particular Roses. Hence were some of the time mostly spent in protecting Roses in the open against frost devoted to improved modes of culture and the selection of more fragrant, floriferous, and yet more beautiful varieties, the Roses in the new century will far exceed all that have preceded them in making our homes and gardens beautiful.

With your leave, next week I will show a shorter, surer way of making Tea and other Roses more hardy as well as more free-flowering and profitable.

D. T. FISH.

and the homely border flowers are in beauty. Downside is in truth a garden—flowers everywhere and in rich variety.

Rhododendron Brilliant.

Several of the Javanese section of hybrid Rhododendrons are now in flower, and amongst them this variety stands out very conspicuous, owing to the bright scarlet of its beautifully formed blossoms. One of the oldest of all Princess Alexandra, which is white, with just a faint tinge of blush—is flowering with great freedom, and all things considered (particularly its vigorous growth), stamps it as still one of the best of that tint. Treated as warm greenhouse or intermediate house plants, these Rhododendrons are not at all difficult to cultivate, while they flower more or less continuously throughout the entire year, and above all they are not affected by that bane of plant life—London fogs. That Messrs. Veitch show them so well from their Chelsea nursery at all seasons is a good proof of this. T.

GARDENING OF THE WEEK.

CHRYSANTHEMUMS.

BY the time these lines are in print the first batch of Chrysanthemum cuttings that is, those which are intended for producing fine flowers and for growing on into specimen plants should be putting forth their roots, and will soon have to be removed from the propagating frame or pit. Many kinds will be found to strike much more readily than others. It is a great mistake to allow these to remain in the propagating frame after they have commenced to root and be subjected to the same treatment as those in a less forward state even one hour longer than is necessary, or premature growth will be the consequence. It is a most important rule to observe that in all stages of their growth no cooling or forcing should be allowed, but strong, solid foliage and wood built up gradually are most essential if the best results are to be attained, so that they should be looked over daily and the more forward ones removed to another frame in the same house, which may be aired more freely, or a heated pit, placing the plants near the glass on a bed of finely-sifted coal ashes. As soon as it is found that the young plants are sufficiently advanced to withstand sun and air without serious results, such as severe flagging, no harm will arise should the leaves droop slightly when exposed to sun and wind, providing they freshen up again during the evening. Remove the plants to a shelf in the greenhouse as near the glass as possible, where they may be aired freely on all favourable occasions. The plants, being in small pots, should be examined twice daily and thoroughly soaked with water when needed. When the weather is bright, spray over with the syringe in the morning and early afternoon. Without delay make good any cuttings which have failed to strike. Those which were not obtainable before should be brought on as speedily as possible, as it is much better to have the whole of the collection quickly rooted so that they may be treated under the same conditions.

POMPON AND POMPON ANEMONE VARIETIES.

These are, in my opinion, the most useful of all sections of the Chrysanthemum, as they lend themselves readily to nearly all kinds of decorative purposes, either as plants or for cutting purposes, and by a judicious selection of varieties the flowering season can be extended easily from October to well into the new year. Framers of schedules would do well to give more encouragement to these sections by offering respectable prizes for, say, eighteen vases, and, stipulating the number of blooms to be shown, their true beauty would then be brought out; whereas generally at the present time small prizes are offered for twelve varieties, three blooms in a bunch, which are crammed on to an ordinary-sized green painted board, thus robbing them of all their elegance and natural beauty. Cuttings of these should now be put in, and they are best struck in 2½-inch pots and treated in precisely the same way as advised for the larger varieties.

SINGLE KINDS

may also be struck at the same time. These are favourites with many people, and a few of the best distinct coloured kinds are useful for decorative purposes, especially those which stand erect when in flower, but to my mind these are not so beautiful and useful as the foregoing. E. BECKER.

Abraham House Gardens, Elstree, Herts.

SOLANUMS.

To have these popular berried plants in good condition they must be raised early from cuttings, as they require a long season, and seedling plants do not bear freely the first year. The best cuttings are to be had from plants which have been prepared for their production by growing them for a few weeks in heat; the tops of these should be taken off, made into cuttings, dibbled into pots of very sandy soil, and plunged into bottom-heat until

struck, after which they should be potted off singly and stood well up to the glass, pinching them occasionally to induce a bushy habit.

KITCHEN GARDEN.

CARRIOTS

are slower in germinating than Turnips, and will also stand more warmth, though hard forcing should be avoided, especially when first sown. Much the same culture is necessary as in the case of Turnips, a rich light soil being used and the plants grown near the glass. I do not think frame culture can be improved upon, as grown thus the plants get more light and better ventilation than in houses. Many persons sow Radishes with Carrots, drawing the former as soon as large enough. Better results will be obtained, however, if sown separately, as the Radish crop will interfere with the proper development of the Carrots. Vegetable seeds under glass are often sown much too thickly. Most seeds are now so reliable, that there is no need, except in very special cases, to sow so thickly, as if thinning is delayed the crop is ruined in its early stages. For frame culture, Early Nantes and Parisian Forcing are excellent varieties, whilst if more size is needed, Early Gem is specially suitable, or any of the Short Horn section.

POTATOES IN POTS AND FRAMES.

Many can grow a few Potatoes in pots who cannot devote a frame or pit to the plants. Now is a good time to make up the pots, and it is of little importance what sized pots are used, providing too many sets are not placed in them. An 8-inch pot may have three sets. I have used four in the case of dwarf growers, but when this number is used the plants must be given ample food when tubering. If 10-inch or 12-inch pots are employed more produce is obtained, but the advantage of small pots is the ease with which they may be moved about. If frames are used I would advise dwarf kinds, such as Ringleader as the earliest, followed by English Beauty. There are no frame Potatoes superior in quality to a good stock of Ashleaf. Myatt's is still difficult to heat, but this is later and less prolific than those mentioned above. A good depth of soil is needed in the frames, as though a small quantity may suffice at the planting, the new tubers green badly when attaining size, and I find it best to give the soil at the start than later on, as there is then so much work to attend to that it is overlooked. Avoid overheating, and give but little moisture at the outset, as the soil, if in good condition, will be sufficiently damp to maintain growth for the first few weeks.

FORCED SEAKALE.

This will prove more valuable early in the year, as in many gardens the sharp frosts destroyed the Broccoli just turning in. Owing to the late growth many were afraid to lift and shelter, and in consequence the crop was destroyed. I never think Seakale nearly so good after a hot, dry summer as in a cooler one with more moisture; the result is that the growths when forced are less succulent. It will be well to place roots in their forcing quarters (a warm mushroom house is suitable) every fortnight, and, unlike Asparagus, Seakale must be kept quite dark to blanch top growth, otherwise it gets green and is less inviting. It may also be placed in large flower pots or boxes, which should be covered with empty pots or boxes and placed in a temperature of 65 to 70°. Roots in their permanent quarters may likewise be forced with hot litter, and here pots are employed as covers; but it is well to prepare the heating material in advance. If too hot it injures the plant. I prefer to place it in bulk and turn once or twice before being used; it may then be placed in larger quantities. If pans with lids are used the latter may be left off for a few days to allow rank steam to escape.

Syon Gardens, Brentford.

G. WYTHES.

FLOWER GARDEN.

THE LATER VARIETIES OF THE CHRISTMAS ROSE are still in good bloom in sheltered spots and

where, as is often the case, they are afforded the protection of a frame, which in severe weather may be covered over and the plants thus protected from the effects of frost. During heavy gales and rain some covering is advisable for the clumps, or the white blossoms get sadly soiled by earth stains. Where a spare light is not available, a sheet of glass large enough to extend well beyond the outer radius of the plants may be fixed over each clump by driving four strong wooden pegs securely into the ground at the four sides and slipping the edges of the glass into deep notches cut for the purpose on the insides of the pegs. A turn or two of thin copper wire across the top of the glass from head to head of the pegs will render the whole absolutely firm. The sheets of glass prove useful later on for covering boxes of freshly sown seed, and when not in requisition may be stored with the pegs until the succeeding winter. A good time for transplanting Christmas Roses is immediately they have gone out of flower. A deep and rich bed should be prepared for the plants, 3 feet being none too deep. With the lower foot of soil a heavy dressing of cow manure should be incorporated, since the Hellebores are partial to a cool and sustaining subsoil and some well rotted manure added to the upper stratum. On no account must large clumps be transplanted in their entirety, as such a course often results in the death of the plants, however carefully the removal is effected. When the clump is lifted it should be placed in tepid water, and when the soil around the roots is well moistened, this should be washed off with a single jet syringe. When the roots are entirely free from soil the clump should be carefully divided, separating the roots by hand and cutting the crowns apart with a sharp knife. A portion with three crowns is quite large enough for a single plant. These divisions should then be planted 18 inches to 2 feet apart in a few handfuls of fibrous loam and leaf-mould, no manure being allowed to come into direct contact with the roots. A sheltered position is best adapted for the culture of the Christmas Rose, one partially shaded by trees at some little distance being admirably suited to their requirements. A mulching with well-decayed manure and leaf-mould in early spring and large supplies of water during hot weather, with occasional applications of weak liquid manure, tend to promote the vigour of the plants, and thus lay the foundation of an abundant blossoming.

S. W. F.

FRUIT GARDEN.

VINES. The limit of time is reached for pruning late Vines. Any not yet done should be without further delay. If longer deferred, the cut parts will not have time to heal over before the sap begins to rise in the spring, at which time it not healed over bleeding will follow. These remarks are also applicable if Grapes are on them. Make clean and slightly slanting cuts in front of a prominent bud near the spur of the Vine rod. When cutting the Grapes at this time leave a portion of the wood in front of and behind the bunch, so that the lower part reaches well down into the bottle in which the Grapes are stored, the front buds tending to take away from the bunch any superfluous flow of sap while hanging. The bottles should be placed in a slanting position in racks fixed to the sides of the room, so that the Grapes hang without touching anything.

It is easy to keep Grapes in a dry room heated with hot water and with a ventilator at the apex. Strict attention will be necessary in order to keep the atmosphere of the room dry and sweet with a temperature of about 50°, or a few degrees higher or lower according to the outside temperature. To maintain these conditions keep a very slight warmth in the pipes, and open the ventilator in the warm part of dry days, *i.e.*, from about 9 a.m. to 4 p.m., for the purpose of expelling damp.

Lady Downe's Seedling is the best kind for late keeping, so that other kinds that will not keep so well should be used before it. Look round the bunches weekly and cut out all decayed berries. After the Vines are pruned, clean and dress them, and also cleanse the vinery. The cleaning of Vines comprises the taking off of all bark that is loose.

washing with soap solution at the rate of 8 ozs. of soft soap to a gallon of water, and painting with a mixture of soap water at the same strength as used for washing, with 1-16th of Richards' XL insecticide, and brought to the consistency of paint by the addition of sulphur, clay and cow manure. When this has been done tie the Vine rods closely to the trellis. Take the old soil from the surface of the border down to the roots, and afford a liberal top-dressing of new loam to which has been added some lime rubble and burned soil. The compost is enriched by adding bone-meal at the rate of a 6-inch pot of the meal to each barrow-load of soil.

Treat late Vines from now onwards until the spring with as nearly as possible the same natural surroundings as they would have out of doors, to give complete rest, by keeping theinery ventilators open as far as circumstances will allow, merely excluding frost from the hot-water pipes, if the water is in them, but if they can be emptied no harm will be done to them. Examine the borders of Vines now being started as to their condition of moisture, and if found to be approaching dryness, afford a liberal supply of tepid water. In

FORCING GRAPE VINES.

Nature must be imitated at all seasons in order to be successful. The increase of temperature in the spring is gradual, and in forcing a similar slow increase should be aimed at. If hurrying is necessary it should be done later in the season, when the days are long and sun-heat powerful. Six months should be allowed from the time of starting the Vines to the ripening stage.

Hard-and-fast temperatures are not conducive to successful forcing; they should be approximate to those I give, varying according to outside conditions. They may begin at, say, 50° at night, and 55° in the day with fire-heat, with a rise of 10° to 15° with sun-heat, accompanied by a moist sweet atmosphere, maintained by means of occasional damping.

Vines that have not been previously forced, particularly young and vigorous ones, do not break into growth regularly the full length of the rods, being more inclined to break at the top than bottom. To assist regular breaking, tie them loosely along the lower part of theinery, with a slight curve from the base to the end. Vines previously forced break freely without being tied down.

Vines started earlier and now breaking into growth should, if tied down, be fastened into their permanent position for the season. Suitable temperatures for these are about 57° at night and 65° in the daytime with fire-heat, with a rise of 10° with sun-heat. Increase these temperatures gradually until the flowers begin to open, when they should be 5° higher at all times. Encourage healthy foliage from the beginning by careful ventilation without causing draughts. When the weather will allow it, open the top ventilators a little in the morning, and close early in the afternoon. When it is very mild a crack may be left on during the night.

Where it is contemplated to plant Vines during the spring, preparation may be made by taking out old borders and preparing the new ones. The renewing of a Vine border entails a good deal of labour, but if the work is thoroughly done the border lasts a long time. If the soil at the bottom of the border is damp and unsuitable for the roots, it will be necessary to cover the bottom with concrete, though this will not be needful in the case of a dry, gravelly subsoil. Broken bricks are as good a material for drainage as anything. These should be laid on edge, the largest pieces at the bottom, to a depth of at least 9 inches. If there is sufficient depth for more it will be none the worse. About 2½ feet is a suitable depth of soil, consisting of moderately light loam roughly chopped, to each cartload of which are added one barrow-load each of lime rubble and burnt earth and a peck of finely-crushed bones or bone-meal.

Put in the drainage over the whole space of the border, covering it with soles of loam laid with the grass side downwards. A portion of the

border the full length of theinery and 4 feet wide is all that should at first be made up. This will be sufficient for the Vines for the first year, and can be added to annually as required.

FORCING STRAWBERRIES

is carried on in most gardens, and plants brought indoors now, whether to form a succession or as a first batch, can be depended upon to carry a full crop better than those brought in some time ago, as quantity to some extent has to be sacrificed to earliness. A Strawberry house is a valuable adjunct to a garden, but Strawberries may be grown in other houses in light, airy positions under the same atmospheric conditions as advised for starting Vines. They must be examined frequently and given a thorough supply of water when the soil is found to approach dryness. As the season advances, increase the temperature gradually so that it reaches 55° at night, 60° in the daytime, with a rise of 10° with sun-heat. G. NORMAN.

The Gardens, Hatfield House, Herts.

THE EPIPHYLLUM.

LATELY in THE GARDEN there was a note with reference to this plant speaking highly of it, but

THE EPIPHYLLUM HANGING FROM A GREENHOUSE ROOF.

it always seemed to me that the one great objection to growing it in pots was that the flowers did not show themselves properly, even when grafted on fairly tall stock. It occurred to me to try an experiment as to this, and having grown a strong plant of Pereskia, I planted it out in the conservatory border, and when it had attained a length of about 14 feet I cut off the end, and upon the side breaks I grafted bits of Epiphyllum. The result has been most satisfactory, and now, when it is one mass of flower, one has to lift one's head to look at it, and its full beauty is disclosed. There are some six or seven large bunches from these original grafts, and with this I send you a photograph of one piece which will give you an idea of its general appearance. It has certainly a very uncommon effect, and excites much admiration. I cannot stand the colour of the truncatum section, and therefore grow only E. Macowianum, the flowers of which are a good red. A. KINGSMILL.

Harrow Weald, Middlesex.

SAXIFRAGA OPPOSITIFOLIA.

This is as yet one of my failures, and I shall be glad if any reader will give me instructions how to make it flourish in a dry garden with north and south exposure. E. M. H.

[Saxifraga oppositifolia is not a suitable plant for a dry place. Its home is on cool mountain flanks, where its head is often bathed in mist and its roots feel a frequent trickle of moisture. Ed.]

OUTDOOR CHRYSANTHEMUMS.

Of the two dozen sorts tried last year—and last year was a bad one for them—the best with me was the neat, bright little pompon L'Ami Condorchet (or Conderchet). It forms a compact, shapely bush about 2 feet high, seems to want no staking, and certainly flowers with great freedom. Moreover, the light-yellow blossoms keep clean longer than many, so that the effect of the plants is quite prolonged. Once the best outdoor variety I had was Julie Lagravere, but I lost it somehow, and since then the plants of this variety I get are less hardy, apparently. I expect I do not get the true sort, although I know it is to be had still, for I saw a large quantity used for decoration not long ago. Woodside Park. T. J. W.

NARCISSUS PALLIDUS PRÆCOX.

FEW seem to appreciate the value of this early Trumpet Daffodil. It is flowering now with me under glass, and the delicately-coloured and gracefully-formed flowers make pretty button-holes, or are useful for vase decoration. How much it varies in colour! Some of the blooms I have just cut have a distinctly golden trumpet with almost white perianth, while others bear throughout a delicate primrose tint. This is a vagary of the species, and no error on the seedman's part, as I obtained the bulbs from a firm beyond reproach. In the open, planted on a mossy bank, the buds are already almost showing, and a few hard frosts will do them but little harm. The hardiness and earliness of the flower alone, apart from its beauty, should make it more largely grown than it is at present. F. H. C.

Rye.

ORCHIDS.

DENDROBIUM WARDIANUM.

THE importing season of the Burmese *Dendrobium* has once more returned. The early importations of *D. Wardianum* are eagerly purchased in the sale-rooms annually, while those introduced later in the spring months are almost given away. The result is that those who grow *D. Wardianum* extensively for the supply of cut flowers have discovered that if they wish to secure satisfactory results from the first season's growths, when purchased early a longer growing season is secured, and roots are produced which with lengthening days gradually promote growth. By the time the bright summer weather arrives these growths are enabled to make the best of the warm months and mature satisfactorily before the decline of the days. With late importations the plants cannot be, as a rule, relied upon to complete their growths, and it will generally be found that these are in an active state of growth at the end of September. The pseudo-bulbs, which in the early plants have become brown and are in most instances shedding their leaves, in the late plants will be found altogether unripened and unprepared for the dull winter months, which are the resting period. It is difficult to deal with plants under these circumstances. Unless the outside conditions are exceptionally favourable, shortened and weed-like bulbs are the result. Plants thus retarded rarely regain their normal proportions. I would advise those who wish to replenish their stock or to add this species to their collections to procure what is required, even at the slightly larger outlay in the initial cost.

What becomes of the annual importations of *D. Wardianum* into this country? The early importations generally find their way into private gardens. The nurserymen and trade growers who do not import direct must be content with later importations, but these are generally supplied in good time. It is not a species that can be found growing satisfactorily for many years after importation. I am familiar with a few instances, and do not complain of my own experience in the satisfactory culture of this useful *Dendrobo*. In some places destruction is wilfully brought about by the barbarous treatment adopted of cutting off near the base the whole of the growth as it stands while in bloom, so that the growths may be used for cut flower decoration. This is not only done in private places, but one frequently sees instances where the bulb is cut off in this manner displayed in the florists' shops about London. Such treatment cannot produce desirable results. The flowering of *D. Wardianum* differs altogether from *D. nobile*. The former flowers from the last season's growth, whereas in *D. nobile* the two-year-old bulbs flower, and last year's growths start into growth from the base, so that the removal of the flowering growth is not likely to produce the disastrous effects on the new growths. It is worthy of note that the majority of nurserymen do not stock, as a rule, more than the demand for the current season. This undoubtedly points to the fact that they do not find it desirable to retain the plants longer than is necessary, and prefer imported ones.

I am inclined to think that the chief cause of failure is a want of proper conditions during the resting season. Plants do not take the proper rest sometimes, like other species, and frequently commence growing before the previous growth has reached maturity. It is not generally understood that this is characteristic of the species in its native habitat. One of the most prominent of the Eastern collectors has told me that the young growth often reaches from 9 inches to a foot long before the cool and dry season sets in. Then follows the long season of rest, during which time the lower foliage of these growths are sometimes affected, which is followed by the flowering season. Then comes the deluge of rains, and in a remarkably short period the growths which remained dormant for months start away vigorously and quickly attain their proper dimensions. Many of our best growers have failed in the past in endeavouring to treat the

plants in the same manner as the majority of *Dendrobium* when the young growths are in an active and growing condition. Continuous growth during the proper resting season produces most unsatisfactory results, and it was not until I began to discard this secondary growth that success was gained. The flowering season should be reasonably limited and the plants relieved of the strain which is so often imposed in the endeavour to prolong the beauty of the flowers by cooler and drier conditions after they have become expanded. This is an injurious practice. The flowers should be cut within a reasonable period after they have expanded.

H. J. C.

TREES AND SHRUBS.

SHRUBS FOR DRY SOILS.

IT is not always easy to get shrubs to make satisfactory headway in dry, sandy soil, but few are better than the evergreen *Oleasters*, and at the same time few evergreens with variegated foliage are more showy than *Elaeagnus pungens aurea*, which grows freely and forms a compact bush, the leaves of which are rich yellow, the margins only being green. The

as its underground shoots push freely it soon makes a dense carpet of deep glossy green leafage, which in winter is heavily stained with brownish purple and crimson. Continuous growth during the proper resting season produces most unsatisfactory results, and it was not until I began to discard this secondary growth that success was gained. The flowering season should be reasonably limited and the plants relieved of the strain which is so often imposed in the endeavour to prolong the beauty of the flowers by cooler and drier conditions after they have become expanded. This is an injurious practice. The flowers should be cut within a reasonable period after they have expanded.

THE WINTER HEATH (ERICA CARNEA).

At this season of the year it is charming to see patches of colour formed by this hardy Heath. Frost does not appear to affect its flowering, and it emerges from a covering of snow looking fresh, bright, and cheery. How many spots in the environs of gardens might be made bright during autumn and winter by the free use of such plants as this, its white variety *E. herbarica*, and some of the autumn-flowering native Heaths. They are hardy, but unobtrusive plants, and never look out of place or untidy at any season. J. C. T.

RHODODENDRONS BY WATER.

THE fine effect of a bold grouping of the most free-growing of the *Rhododendrons* on the margin of artificial water is shown in the accompanying

RHODODENDRONS GROUPED BY WATER.

type is of good growth, too, and bears great numbers of small, white, deliciously-scented flowers in axillary clusters in November and December. *E. macrophylla* from Japan is a choice shrub for decorative planting. It is of excellent growth, spreading habit, and its bright green leaves, silvery on the undersides, create a pleasing effect when ruffled by wind. It flowers in mid-winter, and although its greenish yellow blossoms are small, they are borne so abundantly as to merit attention amongst winter-flowering shrubs. The *Oleasters* are perfectly hardy, easily grown, and splendid dry-weather shrubs.

A GOOD SHRUB FOR CARPETING THE GROUND.

DURING winter, *Gaultheria procumbens*, a dwarf-growing North American shrub, is one of the gems of the hardy Heath or rock garden. It forms a good carpet shrub 4 inches or 5 inches high, and

illustration. These grand shrubs are never so happy or so free in growth as when their roots are within sucking distance of a constant supply of water. They will live and do fairly well under drier conditions so long as they are not absolutely parched, but will require constant watching, with judicious mulching and watering when signs of distress are noticed. But if planted at once in peaty soil, or in such as has a good proportion of leaf-mould, and where there is water so near below them that they can easily take it up, they will grow away well and take care of themselves.

Hamamelis arborea. This is one of the most charming of winter-flowering shrubs, with its crowd of golden-colored twisted petals. It is very hardy, moderately vigorous, and should be grouped on the lawn, not crowded into the mixed shrubbery. The other species are far less interesting and attractive.

ONWARD! NOT BACK.

Is your kindly reference to my work in the last issue it is said, that "although the newer and better ways of gardening are only a return to the ways of our ancestors, yet the precious heritage they left us had for many years been lost."

On this I should like to say a few words, not so much on my own behalf as in the interest of the things themselves. The statement is true enough as far as it goes, but it covers but little of the ground. A just view is that which Dean Hole expressed to me last summer, *z.c.*, that we are now beginning to see a beauty in gardens which was never dreamt of in old times. Certainly no one need be ashamed of going back in any art, and much of so-called progress is anything but worthy of the name. Nothing, however, suffers so much from the influence of "survivals" as the garden art, and the watchword there must be "onward" if we are to reap anything like a tithe of the beauty of actual things in many cases wholly unknown to our ancestors.

In saying something as regards the various ways in which distinct advance has been made, I do not by any means try to cover all the ground, even if it were in the power of any one person to do so.

THE ROCK GARDEN.

Perhaps there is no more interesting instance of real progress, and at the same time of the survival of ugliness, than what I call the rock garden. No one can say that this was known to our ancestors, as the earliest evidence we have is that of London's books, which show fearful things and useless for their purpose. Even in our own day we have heard savants and botanists say that alpine flowers could not be cultivated, and the collection of them at Kew even were, as many will perhaps remember, under a canvas cloth. Who among our ancestors would ever have expected to see such rock gardens as that of Miss Willmott, and many others that could be named, in which the true beauty of the flora of the mountains is seen! Here also is an example of the survival of evil things. The ugly old "rockery" idea is unfortunately now being carried out in the costly London parks under the rule of the London County Council. In Dulwich Park, Waterlow Park, and in the squares of London we see rockeries being formed of the vitrified waste and rubbish of the brick-yard. Nurserymen, also, with a reputation for forming rock gardens, erect showy stony piles, using many stones where three would give a better result. Here there is no going back; all progress can but arise from looking to the great mother of things. It is singular how near we are to the mountains, and how little good our garden-makers get from it, and certainly any good we have got is by looking to Nature.

HARDY FLOWERS.

Even in the one way in which we have rightly gone back, that is to say, to the mixed and more natural way of arranging hardy flowers, there is a great change for the better. The old mixed borders were often full of coarse plants, which eat up the few good things. Even in gardens where hardy flowers were best grown, such as the marvellously fertile soil about Edinburgh (as at Comely Bank, Mr. Stirling's garden), while one saw with great pleasure the beauty of the individual plants, there was no grouping or holding things together in the way we now see in some of our best hardy flower gardens, such as Lady Ardilann's flower borders. Nor was it possible that we should have had such gardens of hardy flowers as we

have now, because the rich collections of Lily and Iris and many other flowers were not known in our gardens.

ROSES.

Here, if we go back, we get into the Rose garden of Roses that flower but a few weeks; as Roses were usually placed, except in cottage gardens, in a place apart (the rosery). In consequence of the survival of this rule not one out of fifty Rose lovers even has any idea of the beauty lost in the present day owing to this survival. How it would have rejoiced the hearts of our old gardeners to see a garden of Tea Roses in full beauty months after the old Rose-time had passed! This, although little known to people as yet, is a delight which the simplest cottager can enjoy if he does not pursue the orthodox and settled method of putting all Roses on the wild Brier, or follow the teaching of every list, that Roses to thrive must have rich and heavy soil—not only not true, but the very opposite of truth as regards the finest of all Roses grown in the natural way.

THE WATER GARDEN.

Perhaps there is no greater advance imaginable than has been seen in water and water-side flowers. While everyone has heard of the new Water Lilies, few yet realise the difference they will make to the lake in the future in this water-blest isle. Mr. Watson, of Kew, said to me a summer or two ago on seeing some of these hardy Water Lilies well grown: "What is the use of building Victoria houses if you get results like that in the open air!" It seems to me that a few acres of water set with lovely Water Lilies in various delicate colours and with the margins clad with water-side plants and the banks with the rich hardy plants that may be grown in such soils, offer a picture which, as Dean Hole said, people at one time never dreamed of as possible in a garden. Also, we may claim that many things which were known and grown in the gardens of our ancestors have been more rightly treated in our own day. Take the beautiful Starworts, which in old gardens were tied to a stick like a broom. The new way of growing these in broad groups or colonies of all the more lovely kinds among shrubs or young trees is distinct from anything seen in gardens before, and gives a great charm to the garden in autumn. What is true of these applies to many other beautiful plants, which in the old gardens existed only in a spotty way, and never gave any good clear effects as our beautiful plants do now when we group them in Iris border, Lily garden, or many Narcissi so admirably suited to our climate. The old people had the Narcissus here and there, and a few kinds naturalised themselves in Irish gardens and cool soils; but who expected to see anything like the constellation of lovely beauty in the grass now seen in many places!

FLOWERING TREES AND SHRUBS.

It is not only to the ways we have already realised that my contention applies; it is to things we know and as yet make no fair use of, as, say, the most precious things of all for the open-air garden—flowering trees and shrubs. If there be any place in England where half the beauty these may give us is well shown, I should be very glad to hear of it—I mean the full expression of their beauty in the way the beauty of hardy flowers, bulbs, or Bamboos has been realised in various instances in our gardens. Even the value of the Willows of the north, full of lovely colour as they are every month in the year, is rarely seen in any effective way, and we may see now and then the best examples of water in park or pleasure

ground—as at Bocket—and rivers sweeping through fine country seats without a group or mass of these most beautiful of hardy trees for the water-side being seen.

Without trying to cover the whole ground, I hope I have shown that the word must be "onward." I have not mentioned any advance here of which we have not good evidence of, though, unhappily, it may be unknown to many. Also, that it is a fight only for what is true and right and will carry us to better things in the garden art. This fight may be a long one, especially when it is against the routine of established trade practices, the practice of grafting, for instance, by which nearly all the beautiful shrubs and trees introduced or raised perish, and are in the end lost to gardens, as in the cases of the species of *Catagrus* on the Quick, the lovely varieties of Lilac on the common Privet, and graceful Willows on the common Withy. W. R.

WOODLAND AND FOREST.**FORESTRY: A LOST CROP.**

ONE of the most conspicuous faults of our home system of forestry is the neglect of crops from old stools. It has often been a source of wonder to the writer seeing owners of land incurring much expense in forming extensive plantations of young trees and leaving the stools from felled trees in the older woods untended and mired for, apparently in ignorance of the fact that in every one of the stools left a second crop of trees and poles equal to the first might be had in a much shorter time than was possible from planted trees, and with no more attention than the thinning out of the young shoots that spring in such abundance from the stools of nearly all the hardwoods. These shoots always grow at a rapid rate, due to the rebound of growth caused by cutting down the tree, just as cutting back a branch causes it to break out stronger than before. When a healthy tree is cut down the whole vigour of the roots is concentrated on the reproduction of new growth, and the rapid rate at which such trees as the Oak, Ash, Sycamore, Alder, &c., spring up from the stool far exceeds, for a number of years, the growth of planted trees, which, comparatively, stand still for the first few years. Through want of attention, however, stool crops of timber are practically lost on most estates. Indeed, the writer does not know at the present time where he could point to a good second crop of timber of the kind described. Single, accidental examples are common enough, but what one usually sees in woods from which repeated falls of timber have been taken is just a thicket from each stool neither fit for timber nor coppice—pure waste. Travelling through part of Lincoln and Nottinghamshire not long since, I could not help noticing numerous examples of this kind. The neglect of this branch of forestry on estates in England is far from creditable to the management. We know fine Oak and Ash woods in Yorkshire in which nothing has ever been done to rescue the second crop from destruction, and the woods have had regular falls of timber taken out of them so long that they are now much too thin, the shoots from the stools having been either eaten off by rabbits as fast as they grew, or been allowed to become smothered with weeds and bracken at the critical stage. This neglect did not exist always, however, judging from the signs one occasionally sees. On certain well-known

estates where extensive falls of timber were got many years ago provision was made in the printed agreements between vendor and purchaser that the trees were to be felled at the right season, viz., autumn or winter, when the sap was down, and that the trees were to be cleanly cut close to the ground so as not to check future growth from the stool. In the case of trees peeled standing, as is done in South Yorkshire, the trees had to be ringed or "burled" at the base to prevent the bark on the stool from being injured.

The Germans and French are ahead of us in this matter, as in others. In German books on forestry the reproductive power of different species of trees from the stool is carefully noted, and some fine examples of second crops are to be seen on the Continent. There was twenty years ago a model second crop of Oak to be seen in the beautiful forest of Fontainebleau, about 40 miles south of Paris and close to the little station of Thomery. This forest corresponds to some of the Crown forests in this country in a sense; but as regards good order, management, and productiveness there is no comparison. Fontainebleau Forest is kept up as a royal forest, but it is managed on strict sylvicultural lines. In the second crop of poles alluded to the trees were about 60 feet high, and from two to four poles sprang from every stool. No doubt many more had been produced at the beginning, but they had been carefully weeded out in good time. The whole of the first crop had gone down in a "clear cut" and been succeeded by the one we saw. The regularity of the crop and even uniform size of the trees were remarkable, indicating the attention bestowed on the forest. As before stated, all the broad-leaved forest trees except the Beech possess great reproductive power from the stool after felling, and this power lasts for years in the case of the Oak and others. It is quite surprising how quickly the second crop springs up. The first year the shoots are not so long, but the second year they shoot up several feet, and in two or three years quite a young plantation is established. We have seen single Oak stools from which, by accident or design, the shoots had been reduced at an early stage bearing a crop of six fine poles about fifty years after the original tree had been felled. About twelve years ago a thin Oak wood that we knew was cut down and the ground replanted with Firs between the Oak stools, which produced vigorous shoots that were early thinned, and they are now ahead of the Firs and likely to produce a fine second crop.

We strongly commend this subject to the owners of woods. The second crop of timber in our woods is at present practically a lost crop, though one of the easiest and cheapest to secure. Let owners look round them when they go into their woods from which falls of timber have been removed. Whenever shoots are seen springing up there is a possible crop of timber. As a rule the shoots spring up in great profusion from each stool, forming dense, bush-like masses, and that is where the danger to the crop lies, as if the stools are left in that

state the smothering process sets in. The thinning out of the shoots is, however, a very easy matter, and consists in simply cutting or wrenching out the shoots that are not wanted and leaving about four or five of the strongest to each stool.

J. SIMPSON.

NOTES FROM NURSERY GARDENS.

CHINESE PRIMULAS AT MESSRS. SUTTON AND SONS'.

CHINESE PRIMULA time at Reading is a bright period of the year under glass. When leaden skies and keen winds drive one from the pleasure

Reading, is a distinct break away; its finely-formed single flower, its whitish petals relieved by a crimson shaded central ring and eye of greenish yellow, is entirely unique, and such a departure as this is only the beginning of a new set, so to speak, from this quaint and beautiful novelty.

THE SINGLE-FLOWERED PRIMULAS.

We have written of the flowers here on previous occasions, but every visit reveals some fresh and beautiful variety. The Duchess, as we have already remarked, is an acquisition likely to prove the forerunner of a new and charming race, and other seedlings were there also, all possessing distinct features of excellence. These seedlings, chosen from extensive trials, are the outcome of patient work to seize upon every cross likely to prove the

basis of future groups, and in this way gradually and surely has this beautiful family arisen. It is hardly necessary to individualise. There were Reading Scarlet, Brilliant Rose, that beautiful and popular white flower The Pearl, Reading Blue, the delicately tinted Cambridge Blue, the exquisite Fern-leaved Purity, Snowdrift, and the noble series of giant flowers in several colours—pink, the remarkably distinct terracotta, and crimson. The giant group flowers rather later than the other type, and forms in a way a pleasing and valuable succession.

But there is another type, which some prefer even to the beautiful flowers already mentioned, and this group is called stellata, or the Star Primula, in allusion to the somewhat starry form of the flowers. By this one must not suppose the flowers are poor in form, for this group is of extreme elegance—tiers of blossoms, a profusion that fills the house with beauty and provides material for room and table decoration. An example in a pot is illustrated to show the character of this fine section of Primula, which, if it reminds one of the wild species, appeals to the lover of flowers by its freedom and vigour. The type, so to speak, has white flowers, which with age become flaked with colour; but this does not detract in the slightest degree from the beauty of the flower. The pink forms a strong contrast; the colour is pure and distinct and very charming against the older form. Those who care little for the more formal kinds of Chinese Primula will treasure this free and graceful flower, which we hope in time will develop other colours as pleasing as those already in existence.

THE DOUBLE-FLOWERED VARIETIES.

We confess to a strong love for this bright group of winter flowers, and the variety given an award of merit by the Royal Horticultural Society at its last meeting is a great gain. There are no poor colours in the double-flowered strain, and this deep crimson, as rich and precious as the colour of a Clove Carnation, will promote an even deeper interest in this section. The flower is pretty in form, somewhat approaching a rosette, and intense in shade. General French is the name of this sterling novelty. Even in the dimly-lighted Drill Hall this colour, grouped with the scarlet, blue, white, and pink shades, was conspicuous amongst the double kinds. A very pretty set is named Moss-curl'd, in allusion to the Moss-like character of the leaves, and it represents several colours, all pretty and distinct. No variety, however, interests the writer more than the double blue, which from a poor, undecided colour has changed to a pure and delightful shade. The Messrs. Sutton have striven diligently to bring this group to perfection, and the latest addition is, for colour and form, finer perhaps than anything that has yet appeared,

THE "STAR" PRIMULA (P. STELLATA).

garden, it is agreeable to see flowers filling the plant house, groups of colour, crimson, blue, or a strong approach to that distinct hue, rose, pink, and purest white. At the time of our visit the Persian Cyclamens were fading, with Chinese Primulas in profusion to carry on the bright colouring into the early spring months. At the last meeting of the Royal Horticultural Society one of the chief features consisted of the group of Primulas from Reading, and even in the murky light of the Drill Hall the flowers were very effective. How great has been the march of the hybridist one may judge from the flowers of the present day, and progress is written large upon Primula hybridisation even at this time, when improvement and extension of varieties seem impossible. This is not so. The variety named Duchess, raised at

[JANUARY 27, 1900.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editors invite readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object they wish to make the "Answers to Correspondents" column a conspicuous feature, and when queries are printed, they hope that their readers will kindly give inquirers the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITORS of THE GARDEN, accompanied by name and address of the sender.

The Editors welcome photographs, articles, and notes, but they will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, they will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editors ask that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editors will not be responsible for the return of artistic or literary contributions which they may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

THE PHARMACEUTICAL SOCIETY.

THE SALE OF INSECTICIDES.

THE Pharmaceutical Society was pro-
fessedly incorporated for the public
benefit, more particularly to secure
that the sale of poisons and the dis-
pensing of drugs should be only
undertaken by persons properly trained and
qualified for the work. Everyone will admit
that it is to the advantage of the community
that physicians' prescriptions should be com-
pounded by skilled hands, and it will be
equally patent that it would not be for the
good of the community if some of the more
dangerous preparations of the chemist could be
dispersed broadcast by anyone who chose to
indulge in the trade for purposes of mere profit.
It conduces to the public weal that supervision
should be exercised by a recognised authority
over the retail vendors of poisons, and that in
the case of certain special preparations a
register of retail sales must be kept, in which
must be entered the date of the sale and the
name and address of the purchaser, together
with the purpose for which he stated the
material was intended to be used. Such regu-
lations are for the good of the public, and
should be properly enforced.

During recent years the Pharmaceutical
Society has evinced considerable activity in
detecting the sales of proprietary medicines

containing poison by unqualified persons—a
legitimate sphere for its operations, and one
in which much good work has been accom-
plished—but the society seems to have now
taken quite a new view of its *raison d'être*,
and is concerning itself with matters outside
its proper province.

The development of the market-garden in-
dustry and of fruit and flower culture has led
to the more systematic study of insectal and
fungoid pests, one result of which is that a
number of special preparations, known as in-
secticides, have been placed on the market, and
have now come into common and every-day use.
Naturally, the active principle of some of these
preparations is a poison, and so on a sale by
retail by a person who is not a duly qualified
chemist there is a technical breach of the law,
even though the vendor purchases from a
manufacturing chemist, and sells in a closed
sealed package, duly labelled, and never opened
by himself. Nicotine is well known to be an
active principle of one or more of the insecti-
cides in common use, and nicotine is a poisonous
vegetable alkaloid, and, as such, is a poison
comprised in the schedule to the Pharmacy Act
of 1868, and recently proceedings have been
instituted against a seller of such a preparation
for committing a breach of the Pharmacy Act.
This preparation has been before the public for
some seven years, and yet proceedings are now
instituted for the first time. Will anyone
contend that the sale of a fumigative contain-
ing nicotine for use in gardens is a source of
danger to the community unless sold by a
qualified chemist?

It undoubtedly appears that in this matter
the Pharmaceutical Society are simply acting
as a trade protection society, and the plea that
the action is taken in the public interest is
misleading; they seek to secure to chemists
and druggists such profit as may arise from the
retail sale of insecticides, and to prevent anyone
else from participating in the profits of such
sales. One result will inevitably be to raise
the price to the consumer, but, happily, the
gardening industry is not asleep, and a society
is being organised to resist the movement (Mr.
G. H. Richards, of 128, Southwark Street, is
acting as hon. secretary *pro tem.*), and to secure
the amendment of the Act of 1868 so as to
enable agents, other than pharmacists, to sell
in the manufacturers' original packages poison-
ous preparations for technical purposes to the
trades and professions ordinarily requiring such
preparations in the course of their trade or
business. Certain restrictions might be found

necessary, to which, however, no one would
object.

One large manufacturer has asked the mem-
bers of the seed and nursery trade to send
their orders direct to him, and he will despatch
to their buyers and invoice the goods to the
merchant, who in turn will invoice to his
customers, but, happily, the decision in the
recent case of the Pharmaceutical Society *v.*
White has shown that it is scarcely necessary
to resort to such a roundabout procedure.
Mr. White, who is a florist at Worcester, is in
the habit of selling a weed-killer containing
arsenic; he does not keep the material in stock,
but forwards his customers' orders to the
Boundary Chemical Company at Liverpool,
who execute the orders and allow Mr. White
25% on the annual sales through himself. The
Pharmaceutical Society proceeded against Mr.
White in the County Court, but the judge
decided that Mr. White was merely acting as
agent for the Liverpool company. The society
appealed to the Court of Queen's Bench, and
last week a Divisional Court (Justices Grantham
and Channell) held that the decision of the
County Court was right, and dismissed the
appeal. Justice Grantham said that in his
opinion Mr. White was merely the conduit-pipe
between the company and the buyers, while
Justice Channell said there was no evidence
that Mr. White had the control or the manage-
ment of the sale.

The Pharmaceutical Society intend to take
the case to the Court of Appeal, but there is
little cause to fear that the decision of the
Divisional Court will be reversed. During the
last few days a question was addressed to the
Lord Advocate (Mr. A. G. Murray, Q.C.) by
Mr. M. Cuthbertson, at a large public meeting,
asking if he would support a Bill in Parliament
making it legal for seedsmen and other agents
to sell poisonous preparations, such as sheep-
dips, insecticides, weed-killers, &c., and the
Lord Advocate replied that where poisonous
substances were dealt with in the way of being
dispensed, it was only right that this should be
done only by qualified persons. But in his
view, where they did not need to be dispensed,
but were supplied by the manufacturer in the
final form in which they were to be applied, he
saw no reason why any trade or profession
should have a monopoly of selling them, pro-
vided proper regulations were made and
precautions taken that they would not be
supplied or used for any other purposes than
those for which they were meant. And this
is nothing more than the trade is fully prepared

to admit, and it is a happy augury for the gardening trade that the decision in White's case, and the remarks of the distinguished lawyer who now fills the position of Lord Advocate, should become known at this juncture.

FALSE IDEALS.

ALL those of your readers who, like myself, love the flowers in their gardens from an artistic point of view, for their intrinsic beauty rather than for their novelty or rarity, will be grateful to you for your able article, entitled "False Ideals," which appeared in your number for January 20—"Nature is made better by no mean, but Nature makes that mean."

So long as we follow the lead which Nature, as it were, points out to us, we are on safe ground, for by assisting her in the way of her own direction, increase of beauty frequently rewards our labours. When a plant has a natural tendency to double its blossoms, or crosses easily by fertilisation, the results are nearly always interesting and satisfactory; but whenever she has distinctly marked out the character and purpose of a plant, and so fitted it that it shall do its best for the general effect in the place amongst its fellows which she intends it to occupy, it seems to me to be folly for the cultivator to interfere; by so doing, novelties and monstrosities may very likely be secured, but an increase of beauty never.

How obviously Nature has intended that the Pea should climb, that its lovely winged blooms may be exalted in the sunshine and air. "Here are Sweet Peas, on tiptoe for a flight." So conveniently raised too for us to enjoy more thoroughly their beauty and their scent. Our florists have lately done much for us by increasing the variety and beauty of the colouring of this exquisite flower, and we tender them our grateful thanks. But what demon could have possessed them to introduce the dwarfed varieties that now figure so frequently in the catalogues! "Cupids," forsooth! To me it seems little short of downright cruelty to sow Sweet Peas like these which are condemned to grovel on the ground during their short existence. The dwarf and compact habit is no doubt a virtue with many things, like the carpeting plants and mosses for instance, but it would be fatal to the beauty of others such as the Teasels, Mulleins or Roses.

To anyone who has worked in a garden for a few years, the temptation to secure plants that are dwarf and compact is no doubt very strong, so many things, especially amongst annuals, having such a tendency to grow beyond all bounds. The labour spent on keeping the borders tidy becomes great and unceasing; this no doubt accounts for the demand for these dwarf things, and I suspect that they are very welcome to the paid gardener as a means of saving labour. Still, after all, beauty is the principal thing, and no sacrifice should be grudged in our endeavours to secure it. Extreme tidiness in the flower borders is not so important a matter as many people think. A wild luxuriant tangle, so long as there are plenty of flowers, is, in my opinion, very much more beautiful than a border in which each plant is severely kept to itself, with neatly raked soil around. Nothing is more delightful than the accidental beauty which results from one plant growing into and amongst another, and I would rather see even weeds than bare soil anywhere. In painting pictures, one of the greatest gifts the artist can possess is a right sense of when to leave his work alone,

and it is precisely the same in the treatment of flower borders, which as a rule suffer far more from continual interference than from occasional neglect. It is extremely difficult to get a professional gardener to feel the truth of this, for he is naturally very proud of his skill, and too apt to imagine that the beauty and success of the garden is all the result of his own attention and intelligence: he is sure to get a very large amount of praise for the symmetry and gorgeousness of the effects which he produces from numbers of people whose taste is indiscriminating, such praise leading him to regard any suggestions of artistic improvement that may be offered to him as the vagaries of amateur ignorance. It is on this account that I feel so grateful to you for giving the subject the benefit of your powerful advocacy.

Riverside, Wallingford.

THE FLOWER GARDEN.

VIOLETS IN FRAMES IN WINTER.

I AM afraid many gardeners were caught napping on the occasion of the late severe frost and had their frame Violets badly nipped, as, owing to the mild weather which preceded it, the foliage was very soft and tender. Those whose frames were sufficiently protected to exclude frost, and who have been careful in airing, watering, and surface stirring, which latter preserves the plants from damp, which is the Violet grower's worst enemy, will now be rewarded by seeing them strengthen. The blooms will consequently improve both in size and colour, as it is wonderful what a change slightly lengthening days and increased solar heat make to Violets. On calm bright days remove the lights from the frames entirely, so as to dry and sweeten the soil about the plants, removing at frequent intervals all decayed and yellow leaves. If water is needed, let it be given on a fine day, so that the foliage will dry before nightfall. It is now time a plot was selected for the summer growth of the plants. Aspect is of great importance, as very few succeed in growing first-rate Violets on sites fully exposed to the sun, as in this case red spider is almost certain to work mischief, as moisture is deficient. An east border is in my opinion the best position, as the sun shines on the plants for a few hours in the morning, and they are left comparatively cool for the rest of the day. Digging in a quantity of rich farmyard manure is not a good practice, as although the plants may make strong rank foliage, they always stand ordinary winters badly, and bloom-production is not satisfactory. What is wanted is healthy medium-sized foliage and prominent well-matured crowns, and these are best ensured, not by strong stimulant, but by the free incorporation of loamy compost, road scrapings, leaf mould, and burnt garden refuse. Mix this to a depth of 15 inches or 18 inches now and let it lie roughly till planting time (the end of April) arrives. Do not plant spider-infested runners on any account.

NORWICH.

MR. G. F. WILSON'S LILIES.

By all plant lovers the name of Mr. Wilson is closely identified with many Japanese Lilies, but a fact not so generally known is that he was the first to exhibit *Lilium Harrisii* (Easter Lily of Bermuda) in flower. This was at a meeting of the Royal Horticultural Society, then held at Kensington, on June 12, 1883, when a first-class certificate was awarded it. The long white trumpets of this charming Lily attracted a good deal of attention, and even more later on, for it was exhibited at an evening meeting at Burlington House on the same day. Despite its many

admirers on that occasion, it is very questionable if anyone anticipated the popularity it would so soon attain and its high commercial value, for the culture of *L. Harrisii*, in many instances at least, has been very remunerative. It was our American cousins who first directed attention to *Lilium Harrisii*, and the production of its blossoms quite early in the year is one of the many wrinkles we have learnt from our friends across the Atlantic.

PLANTING A BED.

"J. W." asks for advice about planting a round bed 10 feet across that has a vase about 4 feet high in the middle. He wishes to do something better than quite common-place bedding. The bed is in a conspicuous place, with a grass verge and gravel walk round; it is near hardy flower borders, with shrubs beyond.

We are not told what is the nature of the plinth on which the vase stands, but as it is 4 feet high we suppose it has some kind of support. We take it to be a square plinth 2 feet each way in plan; it may be round, but to suppose it square will help the description. Next to each of the four sides we plant a large-flowered *Canna*, the four *Cannas* being all of the same green-leaved variety with soft scarlet flowers, such as *Antoine Bouvier*. Between each of these is plunged a well-grown potted clump of some handsome Lily, of which a succession is kept ready. The earliest batches would be the large longiflorum or *Harrisii*, the next *candidum*, then *speciosum*, and lastly *auratum*. Next in front of the *Lilium* should be three permanent plants of *Funkia subcordata grandiflora* in a group together, two back and one forward, and the rest of the space towards the edge of the bed should be of a zonal *Geranium* of a soft scarlet, such as *Mme. Bartlemann* or the splendid salmon-coloured *King of Denmark*, avoiding the hard scarlets, for though they are more brilliant in detail they never make so harmonious a grouping with other plants. Of the foregoing plants the only ones that remain in the bed from year to year are the *Funkias*. Except in warm places in the more favoured parts of our islands, they cannot be depended upon to flower, but in such a bed as the one described the object is not so much for flower as for groups of handsome fresh green foliage. In less favoured places they could be plunged like the Lilies.

Where the *Funkias* do well in the open—and they remain from year to year in the bed—they would equally take a part in another good arrangement of quite different colouring. In this case the Lilies would be the same, but the four *Cannas* would be replaced by well-grown plants of variegated or silver-striped *Maize*, and the front spaces would be of some arrangement of *Cineraria maritima* and a good medium-coloured *Heliotrope*, such as *President Garfield*—the *Cineraria* in a group of three next the *Maize*, the front plant of the three breaking forward into the *Heliotrope*. With this colouring a pretty incident would be a potted *Clematis*, either white or lilac, plunged at any point next the base of the vase and trained upward and around it. The vase itself should, in the first arrangement, have either a *Geranium* to match one of those below, or a small *Canna* of rather dwarf habit; in the second, a pot of *Phormium* might be placed in the vase, or a well-grown two-year-old *Cineraria maritima*.

PROPAGATING YUCCA GLORIOSA.

THE well-known Adam's Needle, with its formidable spiked leaves, seems an unlikely subject to take in hand for propagation by cuttings. But I have found that single crowns, taken off with a short piece of stem, strike as easily as Willows. Some years ago two large specimens were sent me. They flowered, and then, in their usual fashion, split up into several heads. I reduced the number to prevent the plants growing unshapely, and now have several neat specimens, obtained simply by putting the pieces taken off into the border. Some I put into large pots, and these did just as well.

Woolside Park.

T. J. W.

THE ROSE GARDENS OF MIDAS.

It is much to be regretted that we do not know more concerning the Rose gardens of Midas, the earliest Rose gardens of which we find any legend or record. Herodotus, the father of history, who published his writings about 450 years before the Christian era, speaks of "The gardens of Midas the son of Gordius" as if they still existed in his own time. He says they were situated at the foot of Mount Bermus, in Macedonia, and that self-planted Roses grew in them bearing sixty petals on each flower, and being the most fragrant of all Roses.

Midas, king of Phrygia, lived in mythical times, before Grecian history began; his father Gordius was also king of Phrygia, and tied the famous Gordian knot, which remained unloosed for about 1000 years, till Alexander the Great cut it through with his sword. How the king of Phrygia came to have a garden in Macedonia is not very clear, but it was not farther from his home than the south of France from the home of some English people who have villas and gardens there. Latin classical writers, both before and after the Christian era, speak of these Rose gardens of Midas, but give no particulars about them.

We know very little about the flower gardens of the ancients, only just enough to make us wish to know more. The gardens described by Greek and Latin classical writers were for the most part what we should call kitchen gardens. There were the famous gardens of King Alcibiades, generally reported to have been in Corfu. But Homer, in describing these gardens, does not speak of any flowers, but names several kinds of fruit trees which bore perpetual crops, another crop ripening as soon as one was gathered.

The Athenian garden of the philosopher Epicurus was entirely a vegetable garden. The Roman Emperor Diocletian, when he retired from ruling the world, and devoted his time to gardening at his villa in Dalmatia, told a friend who visited him that no one who had once learnt the pleasure of gardening would wish to rule an empire, and he showed his friend large breadths of Cabbages, all planted with his own hand; but nothing is said of flowers. Virgil is very tantalising. In his poem about bees he says if he had less to say about them, he should like to give more time to telling of the double-bearing rosaries of Pæstum, and would give more particulars concerning the delightful flower garden of an old foreign friend, who had enclosed some waste land on the southern coast of Italy, and was more happy than a king amongst his Daffodils and Hyacinths, his Lilies and Poppies, his Myrtles, and especially his Roses, which were always the earliest in spring, but, adds the poet, I have not time or space, and so—"Prætereo atque aliis postme memoranda relinquo."

Theophrastus, the earliest of Greek botanists, who lived more than a century after Herodotus, says of Roses that they vary much in the number of their petals, some having five, some twelve, some twenty, and upwards, some growing in Macedonia being called hundred-leaved; these are probably the Roses which Herodotus mentions. Theophrastus tells us that transplanting and close pinning, and especially burning down, increase the vigorous growth of the plants.

From Pliny, that voluminous Latin writer on plants and animals, we should expect more information about the cultivation of Roses, considering the enormous demand for them at Rome to use in garlands and feasts. As this demand must have been met by a corresponding supply, there were probably many hundreds of acres covered with Roses near the city; but

the information we get from him about them is meagre. Pliny repeats in Latin what Theophrastus had told us in Greek, and adds that the *Rosa centifolia* of Macedonia, which was not wild, but improved by cultivation, was the same as the *Rosa centifolia* of Campania (probably the flower of Pæstan rosaries). The Rose of Pæneste was the latest variety flowering into winter, the Campanian being the earliest. The Rose of Miletus, a Rose having never more or less than twelve petals, was the deepest in colour; the Rose of Abandæ—both these places being in Caria—was the palest. That of Cyrene, in Africa, was the most fragrant, whilst at Cartagena, in Spain, were Roses which flowered all winter.

Pliny recommends grafting and budding, and growing from suckers, as producing quicker results than raising from seed. A pale-flowered, strong-growing thorny Rose with five petals, found wild in Greece, was used as a stock for budding. He astonishes us most by saying that all the Roses known at Rome were scentless, except two. One he calls *coroneola*, and describes as an autumnal Rose of medium size; the other is the Rose *in cubo nata*, i.e., produced on a Bramble—the Briar Rose (?). This summary of Pliny on Roses affords a fair specimen of the difficulty of coming to any conclusion about the flowers described by the ancients. In the case of a plant so widely cultivated as the Rose, all the garden varieties have probably undergone great change in the course of 2000 years, but we are perplexed by the statement that the Roman Roses were for the most part without fragrance, as it seems at variance with what Herodotus tells us of the Macedonian Roses, and with what Pliny says in other passages. But it may be that the sweetness was washed out by the irrigated bog soil of the suburban gardens which supplied the Roman markets, which, as Horace tells us, made even the Cabbages insipid.

Lequipo nihil est cilius horto.

But to return to the Rose gardens of Midas. Herodotus mentions another incident about them which, though it has nothing to do with Roses, introduces an amusing legend. In the days of Midas there lived an elderly gentleman named Silenus. He had the honour of being private tutor to the young god Bacchus, to whom in some ways he set a very bad example, being nearly always tipsy. But he had other more refined pursuits; he was passionately fond of flowers and an accomplished musician, and he imparted these tastes to his young pupil, in whose honour many musical and floral festivals were instituted. Silenus appears to have been in the habit of straying wherever he thought he could get drink, and it was believed that if he could be caught asleep and bound with a wreath of flowers, he would be so charmed by them as to make no attempt to escape, but would redeem his liberty by singing a series of beautiful songs, or by answering any questions his captors might ask concerning the past, the present, or the future, for he was endowed with prophetic inspiration. This Silenus was once caught by the gardener of the King Midas in the Macedonian garden and taken to the king. Every schoolboy knows the rest of the story, and that the adventure did not end well for Midas.

This is, unfortunately, all we know about the earliest Rose gardens recorded either in verse or prose. If Silenus still continues his wanderings, for he is said to have become immortal—it is hoped that he may some day be caught napping in Edge garden, and the writer will certainly not let him go until he has given a complete list of all the species and varieties

of Rose which grew in the gardens of Midas. This could not fail to be very interesting to all who love the queen of flowers.

Edge Hall, Malpas. C. WOLLEY-DOD.

[In the event of this desired capture being effected and the much-wanted information elicited, we trust that Mr. Wolley-Dod will not fail to immediately communicate it to THE GARDEN. Let us hope that an ample bin of choice Falemian exists in the cellars of Edge Hall.—Eds.]

NOTES OF THE WEEK.

Fatsia japonica out of doors.—This ornamental shrub, better known by the name of *Aralia japonica*, is most effectively planted out in clumps or as single specimens. It has large terminal panicles of white flowers 12 inches high and as much through, while in favourable winters it ripens seed here from which we raise young plants. It grows well in a rich sandy loam with a little rotten manure. The leaves being so leathery are not easily injured by wind.—W. O., *Fota*.

Veronica rupestris.—I suppose all Veronicas may be considered good garden plants, but I know of none that pleases more in its heyday than this kind. It is so accommodating and gives such masses of flowers, that it would be perfect as a rock plant if it did not require keeping strictly within bounds. Each plant is compact enough, but it sows itself a little too readily. I used to let it do so at first, but I found it overrun everything, so I clipped off the flower-stems when the blossoms were going off. It did not mind this in the least, as it is readily increased when required.—T. J. W.

The striped Rudbeckia.—I tried a plant with the terrible name of *Rudbeckia grandicephalum striatum* last year, and found it showy when in full bloom. In its early stage its leafage is rather coarse and its flowers disappointing, but it soon develops long-lasting flowers, which form a distinct break of orange-crimson colour. But be sure and stake it well, for it has a branching habit which makes it top-heavy, whilst the branchlets are brittle as well, and apt to snap off the main stem. Of course, it flowers in the autumn, and its warm tone brightens up the border effectually. It grew about 4 feet high in my strong soil.—T. J. W., *Woodside Park*.

Fruiting of Euonymus japonicus.—A correspondent of the *Gardener's Chronicle*, writing from the Isles of Scilly, remarks upon the unusually abundant fruiting of this useful seaside shrub. We hear the same from Ventnor, Isle of Wight, from whence a friend sends us some fruiting twigs, and says that the berries have been so abundant and so ornamental, that they have been freely used as Christmas decorations. The pods before opening are pale green and nearly spherical, with a short pointed snout at the point where the four divisions will presently open, and display the seeds with their coats of brilliant scarlet.

Gardening for the Hawaiian lepers. In the *Standard* lately a letter appeared from Honolulu in which an interesting account is given of gardening for the lepers in the Hawaiian Islands. The writer says: "In a land where it is never too hot and never too cold; where the warm sunshine of the tropics is tempered by the cool and health-giving breezes from the sea; where bright, clear skies, limitless blue ocean, and mountains dressed in perennial verdure unite to charm the eye on this spot, where Nature has done so much and intelligent human benevolence is actively at work, dwell over 1000 lepers. The Baldwin Home is in charge of Brother Joseph Dutton, who for more than thirteen years has lived among them as a friend and brother. With his aid, and under his direction, the once bare and stony ground on which the Home cottages are located has been cleared and planted with bright-leaved shrubs and flowers. A model garden, where grow the finest of Bananas and sweet Potatoes, gives evidence of

constant and intelligent care, and the inmates of the Home have been taught the blessings that result from wisely directed labour. Milk is supplied from a herd of cows owned by the Board, which range over the peninsula, and fresh vegetables and fruits can now be had all the year round by those who will take the trouble to grow them. There has heretofore been insufficient water for irrigating gardens, but last year the Board had a new and larger main laid at an expense of £1000, and there is now an abundance of good water for all purposes. The 'pai-ai' mentioned in the rations is a preparation of the Taro root, and from it is made 'poi,' the national food of the Hawaiians. They eat it in the form of a paste, and to them it is the staff of life, as bread is to the Europeans."

Apples injured by hail. Some fruit was received by the scientific committee of the Royal Horticultural Society from Mr. Woodward, of Barham Court, Maidstone, which had received severe injuries from hailstones. But, although the skin was cut through and the flesh exposed, this had dried up and so protected the interior, which had not at all decayed. The storm occurred on July 19, 1899. Mr. Michael observed that when birds plunged their beaks into Apples through thirst, the injured spots usually resulted in decay.

Double-flowered Peach trees. In THE GARDEN, December 30, 1899, was published a coloured plate of the bright red-flowered Peach tree, under the name of *Prunus persica magnifica*, this name, it is said, being in accordance with Bentham and Hooker's "Genera Plantarum," but I must say it is entirely against the practical and botanical principles universally adopted. A Peach is no more a Plum than a Pear is an Apple, the generic characters being so evident in the foliage, flesh and stone of the fruit, and in the scent and flavour of the herbaceous part, as to render confusion impossible. Accordingly the name ought to be *Amygdalus persica*. The specific name *magnifica* is also doubtful, the variety generally sold by nurserymen under that name being far inferior in beauty to the type represented in the photo.—D. GÜTHESEF, 20, Rue Albouy, Paris.

Proposed trials in R.H.S. Gardens this year. The following trials of flowers and vegetables will take place this year: *Dahlia* (*Cactus*). New varieties only. Two plants of each should be sent in April. The trial of *Cactus Dahlia* not having been a success in 1899 (on account of the great drought and heat), the whole collection will be grown again this year. *Phlox decussata*.—Two plants of each variety should be sent on or before March 1. *Tulips*.—These have all been received and should make a good display in May. *New Cammies*.—One plant of each should be sent on or before February 1. *Celery and Celeries*. *Pears*. *Potatoes*.—Any new varieties. Also a trial of distinctly early Potatoes, of which both old and new varieties are requested. Tubers to be sent by February 1. *Tomatoes*.—For outdoors only. Seed to be sent before February 1. All of the above should be sent addressed to the Superintendent, Royal Horticultural Society's Gardens, Chiswick, W.

Double Rockets. In THE GARDEN, December 30, 1899, p. 518, Mr. Arnott gives a very interesting note on these plants. It is true they are fast disappearing from our gardens and are now comparatively scarce, but I believe they will soon be plentiful again, large quantities having been sent to England during the last few years. Recently some Paris florists have been using the single kinds, but chiefly the double white varieties, for forcing with complete success, the long racemes of pure white, highly fragrant flowers being greatly admired in the shops of our leading florists in January and February, and I must say that few other flowers could compete with them. Obviously, this practice will soon grow over the Channel, established plants being obtainable at a comparatively low price. As regards the Scotch double white and the old double scarlet or crimson, I should be glad to know the difference, as I was ignorant of their existence. Perhaps Mr. Arnott will satisfy me.—D. GÜTHESEF, 20, Rue Albouy, Paris.

Winter flowering of Yuccas. The last hot and very dry summer seems to have acted in some unusual manner on the Yuccas, as we have at the present time fifteen tall spikes of bloom showing, some with half-opened flowers, which we see with regret, as in the summer they would have been beautiful, but now can never come to perfection. B. A. THORNYCROFT, *Bombriidge, I. of Wight*.

[We hear other complaints of this untimely flowering of Yuccas from gardens on the warm and dry Surrey hills, and it is probably happening in many other places in the south of England. It is no doubt accounted for by the more rapid ripening of the flowering-crowns, brought about by the unusual heat and drought of the late summer.—EBS.]

Heliophila scandens.—Regarding the beauty of this charming climber recently illustrated in THE GARDEN there can be no difference of opinion, but, apart from its ornamental qualities, it is particularly interesting from the fact that climbing members of the order Cruciferae (to which it belongs) are very few in number. According to the *Botanical Magazine*, in which the *Heliophila* was figured, out of this enormous order, containing 180 genera, only two are of climbing habit, viz., the South African *Heliophila* and the Peruvian *Cremolobus*. Some seventy species of *Heliophila* are known to botanists, but few are in cultivation in this country. *H. scandens* was first sent to Kew by Mr. Medley Wood, curator of the Botanic Gardens of Dublin, in 1885, and flowered the following year.—H. P.

Spiræa prunifolia flore-plena.—Though this *Spiræa* is among the earliest of the shrubby kinds to flower when in the open ground, it is rarely seen forced into bloom; but a group of it in No. 4 greenhouse at Kew is just now very attractive, and serves to show its adaptability for such a purpose. It forms a loose-growing bush, and when the long wand-like shoots are studded for a considerable portion of their length with clusters of little white rosettes, it is really charming. As an isolated bush on the lawn, provided it is attended to in the matter of cutting out the old and exhausted wood, and also given an occasional dressing of well-decayed manure, it forms a delightful feature in the spring, while in the autumn it stands out distinct from most *Spiræas* owing to the leaves being frequently suffused with red before they drop.—T.

Toxicophlæa spectabilis.—Flowering as it does in the depth of winter, this stove shrub is now at its best, and a plant or two will when in bloom suffice to perfume a good-sized structure, so fragrant are the small white Jasmine-like blossoms that are produced in clusters from the axils of almost every leaf. Cuttings strike root readily during the growing season, and if potted off as soon as rooted, they make rapid progress. If intended to grow in bush form, the plants must be freely stopped during their earlier stages, as it is naturally somewhat rambling in growth, and may, if required, be treated as a roof or rafter plant. It is a native of tropical Africa, and was at one time generally known as the Winter Sweet, but of late years that name has been monopolised by *Chimonanthus fragrans*. This *Toxicophlæa*, which is also known as *Acocanthera*, belongs to the order Apocynaceæ, and, in common with many of its allies, the milky sap is poisonous.—H. P.

Galanthus Elsäe.—Snowdrops all seem a little late with me this year, and the first flowers of *Galanthus Elsäe* did not open until the new year had begun. I have had it in bloom in December some seasons, but it is always later than *G. Rachelæ*, which was sent from Greece at the same time, although collected on a different mountain. *Galanthus Elsäe* is the more robust of the two here, although it increases very slowly at the root. I have a couple of seedlings from seed saved here from this Snowdrop, and these have flowered a day or two in advance of the original stock. The position is warmer, and this probably accounts for the difference in time of flowering. *G. Elsäe* was found on Mount Athos by Professor Malaffy. In his paper on the Snowdrops, read before the Royal Horticultural Society in March, 1891, and published in THE GARDEN of September 19 of the same

year, Mr. James Allen expressed a fear that it was not very hardy. I have grown it for about six years and find it hardly enough here. I do not think, however, that our late frosts are so injurious as they are at Skepton Mallet and other places similarly situated. The flowers of *G. Elsäe* are not large, but are well formed. It has not the "card-drop" shape I like in some Snowdrops, but it is pretty enough to be prized, especially when it has so few companions of its genus.—S. ARNOTT, *Carsathorn, by Dumfries, N.B.*

Pitcairnia corallina. Though this belongs to the Bromeliads, it is in general appearance widely removed from the more commonly cultivated kinds such as the *Tillandsias*, *Vriesias*, *Echmeas*, and others of this class. This *Pitcairnia* forms a tuft of long, narrow leaves, the entire plant reminding one a good deal of a *Curculigo*, and, regarded only from a foliage point of view, it is decidedly ornamental. Just now a large specimen in the Victoria house at Kew is bearing several spikes of its showy blossoms, and its beauty is thereby much enhanced. The flower-spike springs from the centre of the growth at about 6 inches above the soil, then bends sharply down, and rests on the edge of the pot. It is about a couple of feet in length, and the flowers occupy the upper half. They stand erect on the scape and are of a bright coral-red tint, so that a specimen in bloom is very attractive and distinct. It needs to be in a fairly elevated position to see the flowers at their best. This *Pitcairnia* is a native of New Grenada, and needs to attain a large size before it flowers freely. Blooming, as it does, in the early months of the year is, in most instances, an additional merit.—H. P.

Centropogon Lucyanus.—This is one of the most persistent of winter-flowering stove plants, as its clusters of carmine-crimson tubular blossoms commenced to expand in October, and a succession has been kept up from the same specimens ever since. When the plants have done flowering they should be cut back hard and grown on for another season, or they may be employed as stock plants for the supply of cuttings. A mixture of loam, leaf mould, and sand, with occasional doses of liquid manure as the pots get full of roots, will just meet its requirements. When needed for winter blooming the plants should be encouraged to make good sturdy growth during the summer, in the height of which they may be removed to a frame outside. There seems to be a certain amount of doubt regarding the origin of this *Centropogon*, which, according to the *Revue Horticole*, was the result of fertilising *C. fastuosus* with pollen from *Siphocampylus betulæfolius*. This, however, has been more than once questioned, and the suggestion that it might be a form of the old *C. surinamensis* finds favour with some. Whatever doubt may exist with regard to its origin, there can be none as to it being a most valuable winter-flowering plant.—H. P.

The Date Plum (DIOSPYROS LOTUS).—The note in THE GARDEN, p. 29, on the probably better-known species, *D. Kaki*, is most interesting, and though rarely seen in fruit in this country—at least, I have seen few specimens, and these were given a warm wall in the south—doubtless such summers as we have experienced during the past two years promoted fruitfulness. As stated at p. 29, the fruit at first is not a great favourite; but some trees of the kind referred to I once had under my charge in a cool house furnished much better flavoured fruit than I have seen imported. But my note more concerns the kind called *D. Lotus*. We have some trees probably nearly a hundred years old, and during the past summer our oldest tree perfected fruit. This I thought may interest your readers, as, though smaller than that of *D. Kaki*, they are most interesting, being sweet, somewhat astringent, and about the size of a medium-sized Cherry; they hang until the leaves drop, and this is at the first frost. Our trees are in the open, standing on turf, and, of course, get no protection. I have only noticed perfect fruit. After a very favourable ripening season the trees when in flower are interesting and always bloom freely.—G. WYTHES, *Syon House Gardens, Brentford*.

THE OLD PALACE AT MATHERN AND ITS GARDENS. 1.

OWEN GLENDWR, rising against Henry IV., burnt Llandaff Cathedral in 1402, and destroyed Llandaff Castle, then the chief residence of Bishop Peverell. His successor, Bishop De la Zouche, evidently thought it wiser to live in the more English portion of his diocese—in those lowlands fringing Severn Sea, which had been early settled and reclaimed by the English, and protected against the Welsh raiders of the hill-country of Gwent by a chain of fortalices as well as by the great castles of Cuddicot and Chepstow.

Halfway between these two, the bishops had held the manor of Mathern ever since. In the

decay, and the successors of Bishop Beaw—who died in 1706, after a struggle to keep up episcopal appearances on £400 per annum—ceased to reside in their diocese. What remained of the old palace, after the lead had been stripped from the greater part of its roofs, and its interior woodwork and fittings had been destroyed or removed, was turned into a farmhouse. The gate-house, banqueting hall, and other now useless buildings provided material for barn and cowshed. The chapel was converted into a dairy, the kitchen into a stable.

It is a sad story of wreckage, yet it has its bright page. The degradation of the place from a stately home of "proud prelates" to a neglected farm prevented the classic hand of the 18th century from touching it—from

once more vigorously aiming at the roof-line—were dwindling and dying in the grip of the all-covering Ivy. There was plenty of scope for work with the encouragement of a favourable environment. Given ample and varied stretches of old grey stone in dwelling, out-building, ruin, wall and terrace; given much orcharding of gnarled and venerable Pear and Apple, sloping rapidly down to ancient Willow-fringed fish-ponds; given a pleasant position in finely-wooded surroundings; given a desirable soil of loam, rich, yet porous, formed out of a subsoil of mixed marl and gravel; given a climate which allowed young freshly-planted Myrtle, Pomegranate, Avatia, and other none too hardy shrubs to pass through February, 1895, without flinching—given these, and the

MATHERN PALACE: NORTH-EAST FRONT. FROM THE OLD KITCHEN GARDEN.

6th century, Theodoric, of Glamorgan—receiving his death-wound while defeating the yet pagan Saxon at Tintern—had died and been buried by its holy well. Here De la Zouche set his new palace, as we know from Godwin (the Elizabethan historian of the English bishops), who lived in it two centuries later, and noted the Zouche arms on the great three-storied gate-house which then dominated the entrance, and in the stained glass of the windows.

Milo de Salley, an early Tudor bishop, also proved a great builder, so that Leland could well describe the place as a "preaty pyle in Base Venteland."

But the Reformation dealt hardly with this see. Its lands and revenues were largely alienated and stolen. Its cathedral at Llandaff and its palace at Mathern gradually fell into

piercing its Gothic walls with an even row of sash-window, from hiding its old stone-tiled roof behind a stucco parapet. The north-west elevation, at least, remains to us almost as De Salley left it, and, on the other side, the ruined hall, its thick walls crowned with self-set Lilac bushes and pierced by arched window and doorway, stretches out as an old-world feature into the garden.

Whether, ere the age of poverty and decay set in, a gardening bishop arose I cannot say, though signs of a third terrace show in the field beyond the two which are gardened to-day. But six years ago horticulture was almost limited to Potato patches, in imminent danger of invasion by the surrounding hosts of Nettle, Dock, and Couch Grass. Even the Banksian and China Roses on the walls—now

garden lover has at least good material to work upon. Five years have wrought great change here, and it should need few more to make it a fair example of how some agreeable garden effects can be produced at no great outlay within an old, though sadly neglected setting.

H. AVRAY TIPPING.

[The excellent photographs accompanying this article were taken by Mr. J. E. Laurence, of The Cedars, Chepstow. Ed.]

Fruiting of *Euonymus japonicus*.

I enclose a sprig of the common evergreen *Euonymus* picked from a bush which this year has a considerable number of berries. We have many bushes of this shrub in our garden, but none have ever had berries before; now we have two well-berried specimens. —B. A. THORNYCROFT, *Benbridge, I. of Wight*.

GARDEN THOUGHTS.

COLD WEATHER NOTES.

WALKING to and fro one's garden upon a January morning, one's eyes, albeit seemingly fixed upon bare earth, are in reality aglow with all the forms and the colours revealed to the believer by faith and hope. The moral side of gardening has been on the whole less worked out than the aesthetic, yet that it exists I feel no sort of doubt. The sense of personal responsibility, for instance, that gets borne in upon one from many sides and by many channels, but neither slight nor yet transitory is the responsibility that one feels to owe to one's own defenceless garden. The moralist may frown and the mocker may laugh, but I take it that there is no genuine plant-lover but is more or less acquainted with the sensation. The truth is that we have all embarked upon a very delicate and complicated business, and a good many of us are hardly fit to have the ordering even of the least "important" of our own flower beds. To the really discerning eye the smallest scrap of plant-producing ground, the homeliest corner of earth "long Heath, brown Furze, anything" has potentialities of beauty and interest which even the best gardener rarely develops as they might and ought to be developed. It is not merely that individually our powers are weak, our taste poor, our ignorance great, our imagination defective, but over and above all this we have in most cases not the faintest idea of what we are aiming at. Having no clear vision of what we propose ultimately to produce, how in the name of reason can we hope to produce that, or anything else worth speaking of?

It has happened to me now and then, as to most other bunglers, to bring into existence something that might for a moment be called a plant-picture. Only for a moment, however. Within a terribly brief space of time it has either melted of its own accord off that very mutable canvas upon which we all have to work, or, what is far worse, by some incredible ineptitude of my own I have deliberately spoilt it. The delightful thing was there, and now it has gone, and I might garden throughout a considerable lifetime yet never see that particular aspect of it again.

The cause of the mischance in nine cases out of ten is that we will attempt too much. Our original combination may have been good, but we mean to make it still better. Our gold gets over-gilt: our Lilies are painted till they almost cease to be Lilies at all, and the result is failure all along the line. This sounds the reverse of encouraging, but I am not sure but what it is in some respects better that it should be so. I sometimes suspect that all gardeners—professional and amateurs, experts and gropers alike—are just now rather in a state of flux and indecision. Two chief schools seem to hold

the field, and to be in some respects mutually destructive of one another. There is the school which avows itself the faithful, not to say servile, follower and imitator of Nature, and there is the school that proposes to itself to improve upon her. The tendency of the first is to develop a good deal of picturesque disorder, a pleasant, rather easy-going sense of repose, and possibly some want of definite form and colour. The tendency of the second is to regard their garden as a battle-ground; colour, size, brilliancy, height, as so many tests of their own personal victory, and every plant, species and hybrid alike, as objects for them to shape and manipulate at their own pleasure. Whether the two schools will ultimately com-

not shine forth as they do under a radiant summer sky, nor be so distinctive with brilliant flowers around, but now they are precious because of the bright and cheerful aspect they give to wintry hours; for once the daylight has begun, their spirit form seems vanished, and they are revealed as masses of white blossom netted together and crowning the deep green glossy foliage that spreads luxuriant on every side.

No one who has only seen these Aralias as much-suffering pot-bound plants used for indoor decoration, with their erect bare stems stripped of the lower leafage, and only a bunch of foliage at the summit, can imagine their exuberant outdoor growth, where the stems are many-branched and fresh ones are being constantly thrown up from the base, till the plant assumes a bush-like form.

MATHERN PALACE. FROM THE STABLES.

bine into one harmonious whole; whether the over-strenuous science of the one will serve and strengthen and reform the careless grace and negligence of the other, are questions which must be left to be decided in the still unplumbed future. Here, meanwhile, is our modest brown garden, still sound asleep under its envelope of earth and withered leaves, and one finds oneself gazing down at it with a good deal of affectionate and rather wistful compunction, recalling one's many failings towards it in the past, and its patience under such persistent provocations. Happily, the sin, if it be one, is at least not one of those sins that are irreparable. The past is past: buried in the ground amongst the roots that are already beginning to stir and quicken with fresh life. We have a new year before us, one in which there will be plenty of time to make the fullest and the most ample amends.

EMILY LAWLESS.

Harlethatch, Gomshall, Surrey, January 12, 1900.

ARALIA SIEBOLDI OUT OF DOORS.

UNDER the sombre skies of December nothing is fairer than the blossoming of the Aralias. When I look from my window in the grey dawn, the ivory-white blossoms gleam out of the darkness in a surprising manner, as if white-robed spirits were abroad. It is no doubt the shortened daylight hours that form, as it were, a dusky setting for these blossoms which enhances their worth. They could

surrounded with crowns of blossom from the middle of November until the new year.

The flowers of these Aralias are like glorified Ivy blooms. They commence in a dense cluster, gradually lengthening and expanding until a branched stem is formed, set all the way up with heads of blossom rising one after the other in pyramid form. These flower-stems vary in length from 6 inches to 12 inches. They are thick and fleshy, and have the appearance of ivory.

Beyond an autumn top-dressing and a few good soakings of water when making new growth, they receive no special care. Under evergreens the Aralias do extremely well, enjoying the shade, but in the open they seem of a more robust habit. Even if they have no blossoms, the great, firm, glistening foliage of deepest green would make them ever of value in wintry days, and as they have withstood the frosts of many winters without protection, one may regard them as hardy in a climate not far from the sea.

A. L. L.

SAINTPAULIA IONANTHA.

WELL-GROWN plants of this charming little Gesneriad will flower for months together and at all seasons of the year. They are, however, more valuable, generally speaking, at this time of the year than in the summer, when the choice of flowering subjects is so much greater. Their neat compact growth, great profusion of blossoms, and the pleasing colour of the flowers all tend to form a plant admired by everyone. It has been in cultivation long enough for its requirements to be thoroughly understood, and it is now often met with in good condition. Besides the typical form with its rich violet-purple blossoms, against which the yellow centre stands out conspicuously, we have one known as *rubra* whose flowers are more of a reddish tint, and *alba albescens* in which they are whitish. T.

WOODLAND AND FOREST.

PLANTING FOREST TREES.

A CHANGE NEEDED.

COST OF PRESENT METHODS.

RECENTLY one of your contemporaries discussed the subject of the cost per acre of planting forest trees, one owner of woods asserting that, according to his experience, planting could not be done for less than £10 per acre. It was curious to observe how much difficulty there seemed to be in arriving at a satisfactory conclusion on the subject, and in every case it seemed to be assumed that large plants at a high price must necessarily be used. One does not wonder at landowners being in some doubt on this subject, as the cost of the trees in the first instance always comes to a good sum, and may easily—and often does—reach an extravagant figure.

The cost of planting given in some works on forestry is of little value now, as the price of labour has gone up so much, but if we take even the half of the above estimate, viz., £5 per acre, think what a figure it reaches when hundreds of acres have to be planted. But as planting is carried on on many estates at the present day, £5 would not pay for the plants alone, not to speak of planting and many other incidental expenses. I am assuming that the planting and pitting, &c., is done by contract or piece-work, but in numbers of cases that work is done by the day, and then nobody knows what the rate is, except that it is always high.

THE ONE AND TWO YEARS' SEEDLING SYSTEM.

If, however, the continental system of forestry is adopted in this country, as it soon will be, something like a revolution in raising forest trees and planting will be the result, and probably no class will welcome the change more than nurserymen. At the present time, whether the trees are raised in the home nursery or bought from the nurseryman, they are, as a rule, put out too big and too old at the final planting, and in either case they cost too much. There is no comparison between continental planting and planting in this country. The Germans and French sow their plantations wherever practicable, as their system enables them to do, or they plant out their trees when very young and small, and at a period when, in this country we would be having the plants at the planting stage they would have an established plantation. It must be remembered

that plantations from seed or from very young plants grow much faster than plantations of transplants do. Some may not believe that Firs, for example, from seed will reach a height of 10 feet or more in the period during which the transplanted tree goes through the mere preparatory stage in the nursery. All our nursery-raised forest trees are dwarfed and stunted to prepare them for planting out finally. With hard-wooded trees the case is worse, for whereas a Sycamore or Ash, for example, will

explained between big and little trees! The question is easily answered. Trees from 1 foot to 3 feet high or more and from four to six years of age cannot be planted out in woods with much chance of growing if they have not been frequently transplanted in the nursery to keep them of planting size and fit for removal, and every time a tree is handled it adds to its price, not to mention the time it occupies the ground and incidental expenses. Transplanting millions of forest trees and singling every tree

MATHERS PALACE. FROM THE BOWLING GREEN.

reach a height of 10 feet or 15 feet in a few years from seed, it must be kept at planting size by cutting either root or top in the nursery. On the Continent, we believe, forest trees are rarely or never bought from public nurseries: in fact, continental nurseries do not offer the trees which are raised by the foresters in the woods and put at a title of the cost incurred here. Wherein is the difference in the cost

out separately in the operation is no joke, and nurserymen have to do that several times before the trees go out, and no right forester would buy forest trees that had not been transplanted sufficiently often. And after all this trouble the nurseryman has often many thousands of trees left on his hands that have got beyond the planting stage, and the only thing he can do, and does do with these, is to burn them,

but the cost of rearing must be defrayed out of those trees that are sold.

Now, about the price of plants raised for planting we shall take the ordinary nursery examples. The first cost in planting, say, one acre is the price of the trees, and as not less than 5000 should be planted to the acre, the cost on that head is soon ascertained. One-year seedlings may be used for planting, and, taking the list of Firs and hardwoods ordinarily planted in quantity—less than a dozen, perhaps—these may be had at an average price of about 5s. per 1000. These seedlings have very small tops and disproportionately long roots, which are often six times longer than the top or more. They are easily planted with a dibber or trowel in any soil not covered with rough herbage, like Bracken, for example, and the total cost of planting an acre, including the price of the plants, would be about £2 10s.—that is, 25s. for the 5000 plants and the difference for planting, which would vary according to the wages in the district, but the work should be set out at so much per acre, and not by the day.

Next we take two-year-old plants, which are more certain and just as easily planted, as at that age they have developed the normal leaf and have good little tufts of heads that can be seen; hardwoods are a little larger. The price of these should not exceed 8s. per 1000, and as two-year-olds are just about as easily planted as one-year, the cost per acre should not exceed £3 10s.

Now, planting trees of these sizes and ages is, next to sowing a plantation, almost as expeditious, if anything safer in this country, and by far a surer plan than planting older trees, no matter how often they have been transplanted. The one objection urged against the use of such small trees is that they are apt to be smothered during the first two or three years by rank surface grasses and weeds. This plea has, however, no basis in ordinarily fair land where there is only grass or heather, provided the plants are put out in rows where they can be found, and that they are gone over once a year or so for the first few years, and have the grass pushed off them. I do not mean the bad plan of cutting the grass. All that is needed is a man, with a boy or two on each side of him, each taking a row and clearing each little tree with their feet, hands or a stick. The work is quickly done. Do the work in this wise and I will undertake to say that for few failures, quick and early growth of a plantation, and early over-head canopy, the plan cannot be beaten. At one of our flower shows one day I heard a nurseryman, with many big trees to sell, condemning this plan because the trees got smothered, but that is all nonsense. The smallest seedling tree can be raised in a wood or field just as easily as in a nursery provided the same attention is given to keep the heads of the plants clear to the light. This is the cheapest and every way the best plan if the above directions are attended to. Plant in rows and keep the rows clear, and compare the cost.

THE TRANSPLANTED TREE SYSTEM.

I now come to the common plan of using large transplanted trees from four to five or six years of age, and I take my figures from the present year's catalogue of a well-known firm.

First of all, a distinction must be made between trees raised in the home nursery and those got from a public nursery, because the first ought to be raised more cheaply than the latter. That, however, only happens when the work is done at home on economical lines, as when home transplanting in the nursery is done

by day work instead of by the piece, and in the dawdling way often seen on private estates, I should say that home-raised trees cost more than bought ones. They ought, however, to cost at least 30 or 40 per cent. less.

Assuming that we are dealing with trees from a public nursery, the prices per 1000 rise at once far above those given for one or two-year seedlings, reaching to from 17s. 6d. to 20s. after the first transplanting, and after twice transplanting to from 25s. to 40s. per 1000, according to the kind, such sorts as the Corsican Fir and Douglas Fir being the most expensive among their class. Hardwoods are higher priced, if anything.

These are high prices and will show planters what planting trees of considerable size means, for 5000 trees per acre would mean from £7 to £8 for trees alone. It is the price mainly that has caused planters to use about half the above number to the acre, but no greater mistake could be made, for thick planting should be the rule in all cases, and 3 feet from tree to tree should not be exceeded. It is far better to plant fewer acres than to plant too thinly, as the sooner the ground is completely covered the more progress the trees will make.

Planters will see, then, what planting big trees means—just double, or considerably more than double, the cost.

If nurserymen would only cater more for the small tree system they would undoubtedly sell more trees and lose nothing. But we have got wedded to the big tree system, and if the millions of trees sent out annually from nurseries mean anything, the cost of planting to planters of woods must be on an extravagant scale. J. SIMPSON.

BOOKS.

THE ROSARIAN'S YEAR-BOOK.

THIS year-book for the rosarian, edited by the Rev. H. Honeywood d'Ombain, hon. sec. of the National Rose Society, is always welcome, and that for 1900 contains much interesting and useful information. The portrait of Mr. H. V. Machin forms the frontispiece, with article by Mr. C. J. Graham, in which it is mentioned that "Mr. Machin first took to Rose growing in 1884, and is now by far the largest amateur, and one of the most successful Rose growers in the kingdom, his plants numbering close on to 40,000, mostly of exhibition varieties, although he also has one of the finest collections in England of garden Roses, of which class he is in the very front rank as a first-class exhibitor. . . . I hope that amongst the new subscribers who have joined the society in the last few years, and who in several cases are steadily forging ahead as exhibitors, we may find some who will be as generous supporters to the society and as good exhibitors at their shows as Henry Vessey Machin, who, I may say, without feeling the saying to be otherwise than thoroughly appropriate, is a good specimen of the English country gentleman."

The Rev. J. H. Pemberton contributes "Recollections of some New Roses of 1899," Mr. George Paul, A.M.H., "On Planting and Pruning Garden Roses," the editor "The Rose and the National Rose Society in 1899," Mr. R. E. West "Amateur Rose Culture," Mr. Cecil E. Cart "Standard Roses," and Mr. Edward Mawley, secretary Royal Meteorological Society, and hon. secretary of National Rose Society, "The Weather of the past Rose Year." The book may be obtained from the editor, Westwell Vicarage, Ashford, Kent; price 1s. 3d. post free.

GARDENING OF THE WEEK.

THE FLOWER GARDEN.

IN open weather, ground intended for Violet culture during the summer months may be prepared by trenching and manuring. This is more satisfactory if done several weeks before the rooted runners are planted, at the close of April or commencement of May, than if it is postponed until later, as the manure has then time to mellow before invaded by the rootlets of the plants. In the southern counties a slight slope to the north-west is, perhaps, the most satisfactory exposure for Violets, such a situation being still more desirable if it be partially shaded by tall deciduous trees on the south and east, though these should not stand near enough for their roots to impoverish the ground. The great enemy of the Violet is red spider, and in hot borders during dry summers it is often almost impossible to keep them free from this pest, which ruins the foliage and materially weakens the plants, in bad cases rendering them useless for winter blooming. For this reason summer quarters that are not subject to being baked by the sun from morning to night should be arranged for. On the other hand, constant shade, such as that of an over-shadowing tree, should be avoided, since without a certain amount of sun the clumps will not prove floriferous. Except in cold districts it is a mistake to make Violet beds by walls, especially south walls, as the radiation from these merely invites the ravages of red spider, and even where a copious and constant supply of water is available, the plants often become affected in exceptionally dry summers. Anyone passing by a Violet plantation, part of which is backed by a south wall, while the other part runs into the open garden, in the month of August, after a hot summer, will detect at a glance the difference between the two batches of plants, and note the healthier appearance of those not subjected to the radiation from the wall.

While the weather remains free from frost Roses may still be planted. When they are firmly set in the soil the precaution of drawing up the earth round their shoots to the height of a few inches should be taken, as where this is done the plants are rarely killed back to the roots by subsequent frosts. Briar cuttings, made and laid in during the autumn, may be planted in rows 12 inches apart, the individual cuttings being buried two-thirds of their length in the soil and distant 4 inches from one another. In planting, the soil should be made as firm as possible and mulched with a little old hotbed manure. In spare time alterations in the garden may be decided on and carried out, lawns to be sown, trenched and enriched if necessary, care being taken not to bury the top spit. Laurels and other evergreens may be pruned, not that the present time is preferable to the spring for this operation, but that at the latter period there is usually more work on hand, and therefore less time to attend to such matters. The close of January is a good time for taking cuttings of Chrysanthemums destined for brightening the open garden. Some of the older varieties are well adapted for this method of culture, such as the Christines, the deep maroon Julie Lagravère, George Glenny, Mrs. G. Ruddle, the Golden Jardin des Plantes, and some of the pompons. Sweet Peas sown now in the open will germinate slowly and not be far behind the autumn-sown seed in blooming. In sheltered gardens the Winter Aconite is showing its bright gold cups above its Elizabethan ruff of leafage. In some soils this bright flower spreads quickly, and in these its blooms wither and re-appear again with as much regularity as do the wild Lent Lilies and Bluebells, and with as little need of attention, while in other localities it refuses to establish itself. Pyrus japonica, in a warm corner of a whitewashed cottage wall, is bearing a few vivid crimson blossoms. The Laurustinus bushes are heavy with flower, and some of the shrubby Veronicas are bearing bright bloom-spikes, while the leafless branches of Dogwoods and golden and scarlet Willows give attractive colour to the grey days. S. W. FITZHERBERT.

KITCHEN GARDEN.

GROUND WORK.

ALL arrears of work, such as the alteration of quarters, additions to the soil, manuring and digging, should be pushed on in suitable weather. I have previously referred to the digging and trenching of vacant land, referring to such soils as are easily worked. With heavy clay soils trenching may be deferred till we get more drying winds, as in wet weather wheeling on such land does more harm than good. There should be no further delay in making up walks, and the most important detail is drainage, which if defective should now be overhauled.

Manures will be needed in quantities for the next two or three months, and may be got ready by turning, and to assist in making poor materials good, now is a good time to add liquid from the stables and cowsheds.

The quarters needed for crops may now be marked out, and it is well in all cases to give change of crop whenever possible. No kind of Brassica should follow another, and if unavoidable, it will be well to trench the land, especially if such vegetables as Brussels Sprouts or other strong growers are planted. Time will be saved later on if Pea and Bean stakes are prepared now. Roots should be sorted for planting and seeds purchased.

EARLY SEED-SOWING.

Though too early to sow seeds in the open, I would recommend a start being made under glass. We usually at this season prepare some leaves and warm litter, and place a movable frame on them, with about 6 inches of soil for seed-sowing, and when the soil is in good condition sow such vegetable seeds as are needed for early crops. When manure is used as the heating medium, it will be well to allow the rank steam to evaporate before sowing, and it is a safe plan to get the heating materials in bulk and turn a few times before placing in position.

Brussels Sprouts sown now are valuable for planting out in May, and so also are Cauliflowers. These sown now and, like the sprouts, pricked out in a little warmth will make good plants by the time those sown in the open are just through the soil. Celery plants also sown thus are much stronger than when sown in strong heat. A little Cabbage seed will be useful sown as a succession crop to the spring varieties. Leeks and Lettuces are of value; the latter for early supplies, such kinds as Golden Gem and Commodore Nutt being used. Those grown in a frame will be fit for use in May. Avoid thick sowing, as under glass nearly every seed germinates.

EARLY TOMATOES.

To get fruit early in the spring the cultivator must be on the alert at the beginning of the year, though I find it best to sow for first supplies in the autumn previous. Cuttings from fruiting plants struck in the autumn may now be given a shift and a little more warmth, but avoid over-potting. The same applies to autumn-sown plants. If the plants are planted out, a small quantity of soil will suffice at the start, adding more as growth increases in the shape of top-dressings. Many growers will be obliged to rely upon seed sown now for their early supplies, and to save time I place the pans or pots on a warm pipe to assist germination, but when once through the soil, place the plants as near the glass as possible. It is also a good plan when only a few plants are needed, and these early, to sow three or four seeds in small pots, and when large enough to handle to thin to the strongest, as this saves potting up. Use a light soil for seeds at the start and ample drainage, and a small quantity of wood ashes assists the roots if the soil is poor. Such kinds as Earliest of All, Conference, Eclipse, and Winter Beauty are both early and good.

Syon Gardens, Berks. G. WYTHES.

FRUIT GARDEN.

PEACH TREES.

FORGING. The nearer artificial processes approach to Nature, the greater will be the success. Out-of-doors when the blooms are open bees and spring breezes do the fertilising. I have seen bees brought

inside to do it, with success so far as fertilising the blooms went, but it entailed a great loss amongst the busy little workers. There are various methods of fertilising the blooms. Some gardeners use a camel's-hair pencil, some draw a Pampas Grass plume over the flowers, and some a rabbit's tail. I have used the latter with success for many years. From the time blooms begin to open, about noon on alternate days, go over them, giving the blooms one slight touch; at the same time give the trees a few raps with the hand to cause the pollen to distribute itself.

In the daytime keep warmth in the pipes to maintain a moyant atmosphere, with ventilation at the apex of the house, and when the weather is mild a crack may be left on during the night. While in this stage damp sparingly, and that in the afternoon, an hour or so after fertilising. Temperatures range from 50° at 6 a.m. to 60° through the day with fire-heat, with a rise of 10° with sun-heat.

Later in the season some trees will carry a superabundance of flowers, and, so as not to waste

compound. Give liberal supplies of tepid water when found to be in a state approaching dryness, and it is better to err on the side of giving plenty than to allow trees to suffer for the want of water.

Finish without delay the work of preparing trees for late fruiting and the cleaning of the houses they occupy, washing the woodwork and glass and limewashing the walls. Cut off all old ties from the trees and do what little pruning is required, of which there will not be much, which will consist in taking out old snags and shortening back unripened shoots to a wood bud. Wash the trees with soap water at the rate of 4 oz. of soap to a gallon of water, to which a half pint of Richards' XL washing compound may be added. Apply it with a paint-brush, rubbing it well into the rough bark of old wood, and drawing the brush upwards on shoots with buds on. If the trees are at all likely to be infested with mealy bug or scale, make the before-mentioned wash to the consistency of paint by adding cow manure and clay, and carefully apply it to every part of the trees. If in tying trees there is any strain on the string with thick branches,

A COLONY OF CROCUS SPECIOSUS.

the energy of the trees, these should be thinned before they open to one on each node. After the fruit is set increase the temperature a few degrees, and another means to get them along is to shut the house early in the afternoon, and at the same time syringe with water at the same temperature as the house.

Begin disbudding after the fruit begins to swell. One or two shoots must be left at the base of each piece of wood of the previous year's growth and also the end shoot on the same, or one near to it, to be grown on to the end of the current season and to bear fruit the following one. Disbudding should be done on several occasions, at no time allowing the branches to become crowded, nor to make them appear denuded of shoots. First take off the shoots from the back and front of the trees, and afterwards thin out others as required. From the beginning train young shoots to the front side of the trellis. Young Peach leaves are very subject to be infested with aphides, both black and green; therefore immediately after the flowering period fumigate on calm evenings, for which purpose nothing is so effective as Richards' XL fumigating

place a piece of shred round between the string and the branch.

G. NORMAN.

Hatfield House Gardens, Herts.

CROCUS SPECIOSUS.

This is one of the handsomest of the autumn-flowering Crocuses and one of the easiest to grow; indeed, in some gardens it spreads quickly and becomes almost a weed. Its colour is a fine blue-purple, and the flower is all the more showy because of the handsomely feathered stigmata, of a deep orange, almost scarlet, colour. The leaves develop at the time of flowering, so that it escapes the naked look of some of the species whose flowers come first and whose leaves follow.

Christmas Roses and Pernettya berries, especially the pale pink, in smalt glasses are pretty on the dinner-table, and a flower of Iris alata (we have had some beauties) with Christmas Roses round has a very good effect. GEORGE F. WILSON.

AN ARTIST'S NOTE-BOOK.

TWO DAFFODILS.

THE peculiar value of the *Narcissus*, besides its unchallenged claim to be reckoned our earliest spring flower of truly noble rank, lies in its multiplicity of clear-cut shapes. Between *Corbularia*, which is nearly all crown, and poeticus or the tiny *juncifolius*, which is nearly all perianth, there stretches a long chain of forms, which by intercrossing may be rendered practically endless. Moreover, the comparatively few tender *Narcissi* are willing to infuse their own peculiar beauty into the hardiness of the winter-proof majority. Thus I have many hybrids of *N. triandrus* and of the more tender *Tazettas*, such as *Bazelman major*, which passed unscathed through the terrible winter of 1894-5 in a cold district and without protection.

Here are two flowers from Mr. Moon's true and facile pencil which lie almost at the extreme opposite boundaries of the genus *Narcissus*. One is a hybrid, such as I have described, between poeticus and triandrus. The latter is now well known, and the beautiful photograph in *THE GARDEN* of January 20 portrays it better than words. Yet it is only some sixteen years ago it was introduced as a plant scarcely known to English gardens, though a quite common wild flower in the Spanish peninsula. Those who possess Mr. Oswald Crawford's delightful

book, "Round the Calendar in Portugal," will remember a charming drawing of triandrus blooming in a tangle of wayside herbage, and his description of it as "a little Daffodil no larger than a Snowdrop, that grows here by every wood and by the margin of every brook . . . out of the whole list of European wild flowers I know none so perfect in its grace and modest beauty." This grace it invariably imparts to its hybrids, together with an extremely refined

some of its rivals. Under glass it is very early, and perhaps finer than anything in its class. But out-of-doors, neither its white nor its yellow is so clear and pure as that of *Horsfieldii*, and it has the troublesome trick—in my own soil at least—of breaking up into a crowded mass of offsets too small to bloom, so that a large, well-flowered clump of *Victoria* is scarcely obtainable, while I have seen thirty good flowers on the ten years' undisturbed increase of a single bulb of *Horsfieldii*.

G. H. ENGLEHEART.

THE ROSE GARDEN.

AMATEUR ROSE CULTURE.

IT was in the year 1884 that I determined to try my hand with Roses, and I started with a very small border, and was sufficiently successful to enable me to take a few small prizes. From that time I have made Rose culture my study and delight; and in the work of my small garden I find my greatest recreation, and to that work I believe I owe a large measure of the exceptionally good health with which I am blessed. The more I see of Roses, the more I love them; and here, I may add, that to appreciate thoroughly what Dean Hole very rightly calls the "Queen of Flowers," you must love them. No flower, in my humble opinion, will so well repay you for the attention you give it, and if you mean to be a really successful grower you will find that attention is required practically all the year round. When the beginner starts work the different matters to be considered may be classified as under:

1. To select the position for the border.
2. To prepare the bed.
3. What to plant and how to plant it.

Before giving my ideas on the cultivation, pruning, and manuring of the Rose plantation, I will, for the benefit of beginners, say a few words on these three very important matters, for on a correct and thorough commencement so much depends. A good beginning in this case—as in most things—is half the battle. First, then, in

SELECTING THE POSITION.

choose a warm border where the rays of the morning sun may have full play on your plants. If you do not do this, failure is likely to ensue. The Rose tree glories in plenty of sun and air. I have seen Rose trees planted in situations that are only suitable for herbaceous plants, and the owners have been wondering why their Roses came so poor and made such miserable growth. By all means carefully avoid planting near or under trees, for the Rose demands sun and air, not only for the production of the blossom, but for the growth and ripening of the young wood, which in the ensuing year will form the new tree.

The bulk of my trees are twelve years old, yet, owing to cutting away all the old wood every autumn and depending entirely on the young wood, my trees are practically like maidens. Without plenty of sun and air this system would be almost impossible, as I should be unable to ripen off the young wood in the autumn properly. In small London gardens the necessity of sun and air is so often overlooked. You will generally find a small garden has a plot of grass running through the middle of the Rose trees and planted round the outsides under the shelter of the fences or walls, and they cannot obtain sufficient air to thrive. To this error I attribute most of the failures in regard to Rose growing in suburban gardens. In such gardens the Rose bed should be in the centre of the garden, where they can obtain, and take full advantage of, the largest possible supply both of sun and air. Try this plan, and I believe you will be rewarded with a large share of the success you desire. Having selected the position, we now have to consider

HOW TO PREPARE THE BED.

Many growers and exhibitors of Roses go to great expense in the preparation of the bed. No doubt this is the right thing to do, and to those to

NARCISSUS AJAX VICTORIA.
(From a drawing by H. G. Moon.)

and indescribable quality of ivory or creaminess in their white or yellow. My own seedlings in this line, including the one here figured, have been raised from the fine variety of triandrus, which, so far as is known, grows only on the tiny islet of Dréne, one of the *Iles de Gléna*, off the coast of Brittany.

Ajax Victoria is a fine example of the white and yellow Trumpet Daffodil, of which many varieties have been raised in recent years, mostly in Holland. Their parents are the older and more familiar *Horsfieldii* and *Empress*, which they have outstripped in size, but scarcely in refinement or easiness of cultivation. The parentage of *Horsfieldii* and *Empress* has never been precisely known, but whether they came from the old bicolor of gardens or from some similar wild Pyrenean form, their raisers certainly achieved more at one leap than has been done since. *Victoria* is a large and shapely Daffodil, free from the coarseness of

whose expense is no object I would say, by all means prepare the best bed you possibly can; but I want to show that where the conditions are at all favourable this expense is by no means a *sin qua non*; on the other hand, provided due care is exercised in selecting hardy types of Roses when planting, even where the soil and other conditions are not favourable, a considerable amount of success may be obtained without any expensive preparation beyond thorough trenching and manuring. In my own case my only preparation has been thorough digging and manuring; but I admit that I have a very suitable garden for Rose growing. For the information of those who think that an expensive and elaborately prepared bed is an absolute necessity, I may here state that, although I have only about 1250 trees, and being a busy man my time given to gardening is limited to a few hours before breakfast (except in the month of June, when I take my holiday), I do most of the work myself, as I only keep one man, and the remainder of my garden requires most of his time. All the work that he does to the Roses is under my own supervision. My own success, I think, conclusively proves that good Roses can be grown without going to great expense in preparing a bed. One of the most essential things is to have good drainage. Rose roots like moisture, but not cold toes; if the drainage is bad the young roots die and the plant flags. The bed should be trenched and prepared at least two months before you plant the trees, so that the soil may get thoroughly settled down. The manure, which should be mixed with the soil in the preparation of the bed, should be thoroughly rotten cow manure. Stable manure is good, but that from the cow-shed is better. Where the soil is clay do not be discouraged, for the Rose likes some clay, only be sure you have obtained proper drainage. Clay is very retentive; it retains moisture and it also retains manure; and if the clay is well broken up and mixed with our own top soil and a plentiful supply of yellow loam and cow manure, you will have an almost ideal mixture. Where there is no clay and the subsoil is gravel the soil is what we call hungry, because it has no retentive power, and both moisture and manure quickly filter away, and great difficulty is experienced in preventing plant life from being burnt up in dry, hot summers. Here let me remark that watering with hard water direct from the mains is not advisable.

We now come to

WHAT TO PLANT AND HOW TO PLANT IT.

In deciding what kinds of Roses to plant one must be guided by the locality and the general conditions under which the Roses will be grown. I do not propose to go into the merits of the many different varieties of Roses, but will be content with generalising. First, we have standards, half standards, and dwarfs; and of these three for general use I give my emphatic vote in favour of dwarf plants. For special purposes and in special positions standards and half standards have great value, but for general purposes you must adopt dwarfs. It is of these that my beds are made up, and it is on these that I grow all my exhibition blooms, and it is on the cultivation of dwarf Roses that I am writing. Then as to sorts my own beds comprise the best Hybrid Perpetuals, Hybrid Teas, Teas, and Noisettes. The Hybrid Perpetuals are the hardiest and the best for general purposes, but in all suitable spots and where a certain amount of shelter can be arranged for the winter, the Teas and Hybrid Teas should certainly be grown. In the south of London, especially where gravel prevails, the Hybrid Teas and the hardiest of the Teas are especially useful, and even do better than the Hybrid Perpetuals, and I have no doubt that where gravel is in evidence the same result will obtain.

In making the selection for your beds I would advise you to consult some good grower in the neighbourhood either professional or amateur, and get to know from him the names of the Roses which he finds thrive best in your particular locality. Having decided what to plant, we now have to be careful to plant them properly. Before

planting, each tree should be carefully examined, and if any of the roots are found to be damaged, cut the "barked root" away. Having carefully ascertained that all the roots are free from damage, carefully divide them out and use the utmost care in planting not to scratch or damage them. Having put in the tree, with crown just

NARCISSUS (HYBRID) POETICUS AND TRIANDRUS.
(From a drawing by H. G. Moon.)

under the level of the ground, carefully tread the soil firmly round it. Firm planting is absolutely necessary. Here let me say I do not hold with planting when the soil is too wet; choose rather a dry day when the soil can be trodden down tight

without kneading it. When planting, it is a good plan to drive in beside the tree an ordinary short Bamboo cane and tie the leading shoot to it; for should rough weather ensue, the tree will "wobble" about and have a hard fight to obtain a good hold of the ground. The best time to plant in my opinion is about the middle of October. To protect the trees during winter I strongly advocate earthing up Hybrid Perpetuals as well as Teas. This should be done at the first favourable opportunity in October or November, during a dry spell of weather, and it requires very great care in carrying out. Draw the earth close up to the wood, just like earthing up Potatoes. Of course to do this the Roses must have been planted in rows through your beds. I allow 18 inches between the rows and 14 inches between each plant in the row. Before earthing up it is a good plan to tie out the strongest shoots to Bamboo sticks to prevent them blowing about, and I also find the wood ripens much better when so treated; the lower leaves drop off quicker, and the lower buds seem to fatten better. It really seems to assist Nature. I may here mention that after that very, very severe winter which we experienced a few years since, I only had eight dead trees, while my neighbours lost many of theirs. This plainly shows the value of careful and thorough earthing up.

Now, having prepared and planted our Rose beds, we have to consider the year's cultivation and the battles to be fought with the various pests which we shall have to encounter. After giving you my humble opinion on these matters, I shall conclude with a few remarks on exhibiting.

When spring arrives, it brings to the Rose grower most important work. The first is

PRUNING.

On this point opinions are most conflicting. Personally, I hold that early pruning is best for the plant, and I am so strongly of this opinion, that I invariably prune considerably earlier than is considered wise by the majority of the best growers. Last year I pruned very early, and to early pruning I attribute a great deal of my success in the 1898 season. This year I also pruned all my trees in February, and my experience of Rose growing in Reigate is that early pruning is decidedly right, and that in a favourable position, south of London, at any rate after a mild winter, the last week in February is the best time for pruning. The pruning should be done with proper pruning scissors. Generally speaking, only a few buds should be left. The stronger trees do not need cutting quite so close as the weaker ones. The weaker the tree the closer it should be pruned, as the more buds you leave the more shoots there will be making their calls on the strength and vitality of the parent stem. When I prune I always carry a small bottle of carpenter's knotting and brush a little on the cut surface after pruning a few rows. This prevents bleeding, which weakens the plant.

As soon as pruning is finished many growers level down the earth; but I prefer to leave the trees earthed up till March is well advanced. The earth protects the wood, and the sap being unable to find an outlet, no doubt assists root growth, and then young shoots start up, which form the wood for another year. I also notice that although these young shoots make rapid growth, frost does not damage them, whereas if the old wood buds make a rampant start, the frost damages them so much that it is best really to remove them. Having got this far, I always give the ground a good dressing of soot, gypsum, and lime. I believe if insects attempt to come out it settles them; at any rate since I adopted this plan green fly is scarcely ever troublesome in my garden.

As soon as growth is fairly started I give the plants a thorough syringing with cold water every other day early in the morning when we do not get natural rain. I believe it helps the buds to grow, and when once started I never like the shoots to stop growing. Another thing; when a dry time sets in and many people water the ground heavily, I am content to syringe my foliage very early in the morning, and let the plants absorb the moisture through their leaves.

(To be continued.)

TREES AND SHRUBS.

THE BEECH AND ITS VARIETIES.

FAGUS SYLVATICA.

BEING a true native of Britain, the common Beech is one of the most typical and well-known trees of our woods and forests. As a timber-producing tree it is not so valuable as the Oak or Ash, but as regards its beauty and picturesqueness it is not inferior to them or any other of our larger native trees.

the common Ivy perishes. I find, however, that our native Bluebell (*Scilla nutans*) will grow and increase beneath the Beech, and where bulbs can be obtained in sufficient quantity I would recommend their being extensively planted there. A carpet of Bluebells in flower is never more beautiful than when it is associated with the exquisitely tender hues of the young foliage of the Beech.

Like most long-cultivated trees, the Beech has sported into numerous forms. About a score of these have been named and are now grown in botanical collections. Several of them are merely monstrosities, and have no value as ornamental trees for the garden. On the other hand, there are some that ought to be in every garden of sufficient size to accommodate them. These varieties may be distinguished by their differences

out its great arms in a horizontal or slightly drooping direction; from them the smaller branches fall almost vertically, the whole in summer making a tent-like mass of verdure. In

THE VARIETY MILTONENSIS (so-called because it originated at Milton Park, Northamptonshire) the small branches are not so absolutely pendulous as in the previous variety, being more arching in their mode of growth. Several weeping Beeches have been discovered in the forests of Alsace and Lorraine, and have been put into commerce by Messrs. Simon Louis, of Metz. The three following varieties are named after the localities in which they originally occurred: *hornyensis*, *remillyensis*, and *paguyensis*—all of pendulous growth. There is also a handsome weeping variety of the purple Beech.

VIEW IN BURNHAM BEECHES.

Typically a wide-spreading, somewhat round-headed tree, it is specially well suited for growing as an isolated specimen or in isolated groups. In such positions, and when not molested by animals, its lower branches frequently reach down to the soil, and give some of the most charming examples of restless tree beauty. An enormous specimen in the arboretum at Kew is now surrounded by a colony of young vigorous trees, which have originated as layers from the lower branches of the parent tree resting on the ground.

The shade beneath a healthy Beech is so dense that no woody vegetation will thrive there. Even

in habit, in colour of leaf, and in the shape and cutting of the leaf.

Of those whose habit gives them their distinctive characters the most important are the pendulous varieties. There are perhaps half-a-dozen of these, but the two best are *pendula* and *miltonensis*.

THE VARIETY PENDULA

is represented by numerous fine specimens scattered over the British Isles. The best known to me are those in Mr. Anthony Waterer's nursery at Knapp Hill and one in the Lough Nurseries at Cork. This variety does not grow very high, and sends

Of the forms with variously shaped leaves, the handsomest is

HETEROPHYLLA.

It is grown under various names, such as *asplenifolia*, *lacinata*, and *incisa*. The leaves are very variable in outline, sometimes long and narrow (as much as 5 inches long and only $\frac{1}{2}$ inch to $\frac{3}{4}$ inch wide); others are of the same diameter as those of the common Beech, but are divided back to the midrib into narrow, strap-shaped lobes. Very different from this, but almost equally striking, is the variety

MACROPHYLLA.

I have not seen fully-grown specimens of this Beech. It may possibly lose some of its distinctive character then, but young trees are remarkable for the size of the leaves. Last summer I measured some over 5 inches in length and 4 inches in width. They are, perhaps, of a deeper green, but otherwise are similar to the leaves of ordinary Beech. Other varieties in this section that need only be barely mentioned are *quercifolia* (Oak-leaved), *cristata* (crested), *cochleata* (shell-shaped), and *grandidentata* (large-toothed). They are all more or less curiosities and their names sufficiently indicate their peculiarities.

Among the varieties distinguished by coloured or variegated leaves the

PURPLE BEECH (PURPUREA)

is the best known and most popular. Of all our big trees with coloured foliage it is, probably, the finest. Nearly all the purple Beeches in cultivation are the progeny of a tree growing in a forest near Sonderhausen, in Germany, which was discovered in the 18th century. But records exist of other wild specimens of the purple Beech in Switzerland and in the Tyrol. This variety is in its greatest beauty when the leaves are young and of a soft, rosy hue. Trees with variegated and coloured foliage, whilst they have their distinct uses in the garden, are apt in these days to be overplanted. One begins to tire of the variegated *Negundo*, *Prunus Pissardi*, and the like, and it would be a misfortune if the purple Beech fell into the same category. It is a tree more for the garden and park than the wood. Several forms of the purple Beech have been raised from seed in nurseries which vary in the intensity of the purple shade. Of these, the copper Beech (*cuprea*), *atropurpurea*, *major*, and *nigra* are considered the best. A new variety "Swat Magret" (Black Margaret), recently introduced from the Continent, is also highly spoken of.

Messrs. Spath, of Berlin, have during the last few years sent out a new golden-leaved variety of the Beech called

ZLATIA.

It is described as having been found in the mountain forests of Servia and as worthy of comparison with the golden Oak (*Concordia*). From what I have seen of it, it scarcely bears out that description, but is nevertheless, of a pleasing yellow shade, and it appears to thrive well, which is more than can generally be said of the golden Oak.

Of Beeches with parti-coloured foliage, the showiest is *purpurea tricolor*, the purple ground of whose leaves is streaked and edged with pale rose. There are also variegated forms whose leaves are margined and blotched with creamy white and yellow.

W. J. BEAN.

Alphacatum, Ker.

CHRYSANTHEMUMS.

USEFULNESS OF POMPON VARIETIES FOR DECORATION.

PROBABLY owing to the infinite variety of form and colour in the Japanese Chrysanthemums, the charming miniature blossoms of the pompon sorts are rarely met with in private collections. The pompon Chrysanthemums, although somewhat formal in shape, are represented by some exceedingly pretty flowers, and as most of the varieties now catalogued are of easy culture and also embrace a wide range of colouring, their culture may be taken in hand with every prospect of success. Taken as a whole, the plants are distinctly dwarf, comparatively few sorts exceeding a height of 4 feet. The average height of the pompon plants would be somewhere between 3 feet and 3½ feet. Many of the best and most reliable kinds are also bushy in habit, possessing that welcome branching style of growth so well adapted for the adornment of the conservatory. Their period of flowering is a matter of importance, this commencing as early as September and concluding in December with just a few sorts of exceptional decorative merit. A

November display is what is generally aimed at, the bulk of the best sorts being in perfection throughout the month.

What is particularly charming in the midseason pompons is the addition of another type of the same flower. These are known as pompon Anemones, the flowers of which are small and have a centre or disc of quilled florets and a fringe of ray florets. This type of the pompon Chrysanthemum is not grown nearly so largely as it deserves, the grace, beauty, and quaint character of the blossoms adding very materially to their decorative value either as a pot plant or for the purpose of providing cut flowers. White, pink, and other soft tones of colour predominate in the pompon Anemones.

January is the best month for commencing propagating operations, stock at this time as a rule being plentiful and in a healthy condition, so that there will be few failures.

Eight-inch pots for the final potting are ample for most purposes, although growers for exhibition often use them a size larger. The flowers lose their charm to a large extent when the plants are too severely disbudded, as is the practice when large exhibition blooms are grown. A partial disbudding is far more likely to produce a pleasing display, as by these means useful sprays, each carrying several medium-sized blossoms, are obtained. A small selection of the more reliable kinds may well include a proportion of each type, and is as follows:—

Pompons.—William Westlake, golden-yellow; William Kennedy, crimson-amaranth; Mlle. Elise Jordan, soft lilac-pink; Osiris, rosy pink, tipped gold; Vésuve, crimson-red; Dolly, canary-yellow; Perle des Beautés, deep crimson; Mlle. Marthe, white; Prince of Orange, orange-amber; President, rosy crimson; Rosinante, blush-rose; and Harry Hicks, soft pink.

Pompon Anemones.—Emily Rowbottom, creamy white; Marie Stuart, lilac, with sulphur disc; Firefly, scarlet; Antonius, rich yellow; Mme. Montels, white, with yellow disc; Mr. Astie, golden-yellow; Mrs. Wyness, rosy lilac, with yellow disc; and Marguerite de Coi, blush, with yellow disc.

Miniature pompons.—Snowdrop, white; Primrose League, yellow; Miss Gertie Waterer, white, tipped with rosy purple; Victorine, chestnut-brown; and Yellow Gem, yellow.

D. B. CRANE.

FRUIT GARDEN.

CORDON PEARS.

THERE is no other kind of Pear tree that gives such a quick return as the cordon, and by no other description of tree can a wall or trellis be so quickly covered. These are characteristics of some value, more especially to planters placed under certain circumstances. Other advantages that might be claimed for this form of tree are, that a greater variety of fruit can be produced from a given space than by any other, and that it can be grown upon some surfaces unsuitable for other trees.

An opinion prevails that, owing to the restricted character of its growth, the cordon is comparatively short-lived, but whether correct or not I am not qualified to say. The noted trees at Hohne Lacy are the oldest I have seen, but I do not know their age. The oldest under my charge were planted in 1888, and are growing under varied conditions, more particularly with regard to aspect and the height of the walls. The walls face south, east, and west, and their heights are respectively 15 feet, 12 feet, and 4 feet. The trees upon the highest walls are in a vertical position, while those upon the low one are obliquely trained. Our experience causes me to prefer high trees to low ones, for although the conditions of those upon a 15-foot wall are the same as those upon a 4-foot one in every respect (including varieties in many cases) except in the angle at which they are trained, the former are by far the most prolific. I do not think, however, that the angle at which cordons

are trained in any way influences their bearing power. The only advantage derived from training obliquely, which some cultivators consider essential to complete success, appears to consist in the greater run of wall or trellis space to be thus obtained, and for this reason it is advisable to train in this manner upon low walls.

Cordons may be trained upon archways over kitchen garden or other walks, and although, perhaps owing to draught thus created, it is not the most happy mode of cultivation, at the same time covered ways of this kind have a very pleasing effect, make a pleasant promenade in hot weather, and utilise space that might be otherwise wasted. Trees planted by the sides of walks in upright positions, either trained to trellises or stakes 6 feet or 8 feet in height, also afford a pretty effect, and their wants when thus grown can be conveniently attended to. Horizontally-trained trees may also be planted in this position and secured to strong wires placed 15 inches or 18 inches above the soil, and are also suitable for covering borders by the sides of walls occupied by fruit trees, and when grown under these conditions they should be planted near the walks and trained at right angles to them, as by so doing their roots will be placed at the farthest possible distance from those of the wall trees.

The general management of the cordon differs but little from that of other trained trees, yet there are a few points in it that may be noted. Firstly, the distance of the trees apart should be considered. There are here single upright trees placed 1 foot and 1½ feet asunder, and double ones at corresponding distances, and all do well; but were I again planting I should not place single upright trees closer than 1½ feet, and with plenty of room at command should prefer 2 feet. The extra space thus afforded is beneficial both to stem and root development, especially in the case of strong-growing varieties such as *Triomphe de Vieme*, *Pitmaston Duchess*, and *Beurré d'Amanlis*, while it also permits the fruit to be better exposed to the sun, which is a matter of great importance where trees are not in a very sunny position. Trees grown as cordons are usually worked upon surface-rooting stocks and soon suffer in dry weather, so that they need timely attention in the way of being mulched and assisted with liquid or artificial manures after they have reached a full bearing state. We have a tank supplied from the stables, and its contents are freely used, even through the winter and spring months, with manifest benefit.

In the case of cordons, if root-pruning is found necessary, it can be easily accomplished, as can also the replacement of exhausted soil by that which is good. The latter treatment has an invigorating effect upon them, and can be carried into effect at the end of October without endangering the crop.

This brings to mind the evils of overcropping, than which few greater errors in fruit culture can be committed. This applies with extra stress to cordon Pears, especially if planted upon light soils. Walls with an eastern aspect are not the most favourable places for cordon Pears, but varieties that succeed upon them will also do well in most other positions.

A short list of good sorts that are found satisfactory under these conditions may be interesting to intending planters: *Beurré d'Amanlis*, *Beurré d'Anjou*, *Beurré Hardy*, *Beurre Bosc*, *Conférence*, *Doyenné du Comice*, *Durondeau*, *Louise Bonne de Jersey*, and *Marie Louise*. A variety that we find unsatisfactory in this position is *Olivier de Serres*. Upon south and west walls the following late varieties give satisfaction: *Bergamotte d'Espéren*, *Beurré Baltet Père*, *Easter Beurré*, *Gloa Moreeau*, *Marie Benoist*, *Triomphe de Jodoigne*, and *Winter Nelis*.

THOS. COOMER.

The Hendri Gardens, Monmouth.

Lilac Marie Legray. This is one of the best of all Lilacs for forcing, particularly where neat little bushes are required, as it will flower freely in a small state, and both the individual blooms and the clusters thereof are larger than in many other kinds. It is much grown for forcing both here and on the Continent.—F.

CORRESPONDENCE.

NATIONAL ROSE SOCIETY.
COMPETITION IN CHAMPIONSHIP
CLASSES.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Your correspondent, Mr. C. J. Grahame, opens out an important question, *viz.*, how to encourage exhibiting at National Rose Society's exhibitions, though I fear his suggested system would have the contrary effect to that desired.

It is scarcely likely that an exhibitor debarred from exhibiting for the most important prize at any show would care to compete in any of the less important classes. Naturally he would prefer to keep his flowers in reserve for an exhibition where he was under no restriction. The exhibition, therefore, in which he was debarred from the leading class would lose his support, and though this would enable a smaller or less fortunate exhibitor to obtain a first, it would lessen the sum total of the exhibits and probably keep away the best Roses.

I can also see the possibility of a successful exhibitor like Mr. Lindsell being compelled to retire from exhibiting at nearly all the National Rose Society's exhibitions, at least so far as the leading classes are concerned which would in my opinion be a greater loss to the exhibitions than the lack of mere numbers of exhibitors is at the present time.

I do not suppose that there are a dozen exhibitors, or probable exhibitors, who would subscribe to such a system as Mr. Grahame proposes. Surely the average exhibitor has more grit than to cherish the idea of winning a championship (however much he might value such a distinction) on lines that remove the only difficulty from his path. Debar Mr. Lindsell, Mr. B. R. Cant and Messrs. Harkness and Sons from the championships, and the class loses its value and significance: in fact ceases to be a championship.

A question even if the suggestion be acted upon that it would greatly increase the number of exhibitors, or, what is more important, materially improve the quality of the exhibits. I can cite a case where one of our most noteworthy exhibitors, acting on a peevish complaint "that he monopolised certain classes and that he should give smaller exhibitors a chance," generously retired, but not one of those he thus made room for have yet risen above respectable mediocrity.

To my mind the most likely way to increase the number of exhibitors is to apportion the total prize money of each class to each stand according to merit, giving every stand

A PRIZE ACCORDING TO ITS POINTS.

Often enough a few points only divide first and fifth, and the fifth, though helping to the general effect of the show, receives no prize or recognition of any kind.

If an exhibitor had reasonable hopes of making his expenses, he would often put in an appearance when his flowers are not quite to his mind. He would have his "day off" just to see the show and meet his brother rosarians.

I know some people argue that the question of money never comes into the exhibitor's calculations, though strangely enough they must acknowledge that the big prizes always have the largest entries and most exhibits.

With regard to the championships, they do not to my mind always indicate the best growers of a season. Weather has often determined the championship. The champion cup ought to be given to the exhibitor who wins the most of the leading prizes at the whole of the National Rose Society's exhibitions, or during a given time, say from July 1 to 14.

There are many other matters the committee of the National Rose Society might take up besides the above: amongst others, the advisability of holding the Crystal Palace show in a tent, making new rules regarding duplicates, the disfigurement of an exhibition by advertising show cards, the objectionable system of selling flowers during an

exhibition, the clashing of dates of exhibitions and the employment of incompetent judges in important classes, and the desirability of a northern section of the National Rose Society, with control of the Jubilee trophies, &c. E. R. STAVKS.
Rosleigh, Bedale.

CALLISTEPHUS SINENSIS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, It may interest Mr. Kingsmill (p. 27) to know that when flowers of the *Callistephus* (*Sinensis*, the re-introduced plant) were brought to the floral committee table of the Royal Horticultural Society for certificate they were considered so nearly alike to the other flowers in the Drill Hall flowers, by the way, that have been somewhat contemptuously referred to as "degenerate forms of the double China Aster" that it was deemed desirable to consider the flower-heads side by side. This was done, but so closely did these resemble each other, that some members became puzzled, and had to inquire which was which. There is, however, nothing disparaging in all this; it simply proves that a certain percentage of the original blood still remains, and still asserts itself, though ignored as often as it is seen. Too frequently what is spoken of as reversion is perhaps but a bold, vigorous refusal at any cost to become double; a strong, natural clinging to the wild conditions of these things that surpass all the skill and long years of labour on man's part to eliminate or even expel.

The present race of Asters started obviously from the single kind, the one aim being more petals, greater fulness, and so on. But with all this craze for doubling there have ever been single kinds; that percentage that refused to be doubled; that, though weeded out as persistently as they came, still asserted themselves through all the years that are past. It may be that the percentage was being gradually lowered, but it is still seen in the finest types of to-day. My only objection from the first has been directed to these references that made the *Callistephus* a very superior plant to the single Asters, when this single and simple fact is the one in which we rejoice.

As to the latter part of Mr. Kingsmill's note, the past volumes of *THE GARDEN* should be the best guide. Apart from this, however, I will mention that on the re-introduction of *Chimodoxa Lucilia* I was so enamoured of it, that I was glad to secure a single bulb at a cost of 7s. 6d. When I think of this my enthusiasm for the re-introduced species must have been warm indeed. Prior to that, *viz.*, in May, 1875, I was most anxious to get *Tiarella cordifolia* grown by all, and when I exhibited a plant at Kensington, bedecked with its four flowers to show its beauty, I was surprised to find it was quite unknown. The exhibit was not lost, however, as many inquiries reached me respecting it. E. H. JENKINS.
Hampton Hill.

[In reference to a passage in the above note which speaks of the Royal Horticultural Society's floral committee finding a difficulty in deciding on the merits of the single Aster blooms from different sources, it should be borne in mind that it is one of the difficulties that often presents itself when flowers are detached from the plants and taken to a distance for comparison. A good single bloom from a plant of poor habit may easily be found to match a moderate bloom of the handsome bush-like single Aster. If on an occasion like this, where the merits of a good garden plant are being discussed, the committee could have seen the two plants growing, the doubt would not have arisen. Eds.]

DISEASED POTATOES.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I should be very glad if you could tell me what is the disease with which the enclosed Potatoes are affected. We had an apparently fine crop, but they are nearly all diseased. Our soil is a hot, dry sand (greensand). The ground where the Potatoes were grown is in a recently planted orchard, and it had only had one crop (Potatoes)

grown on it the year before. Before that it was fallow except for the fruit trees. It was well cultivated, ploughed, hoed, &c. We grew Pink Beauty of Hebron and White Elephant. The former are the most diseased. Some Myatt's Ashleaf which we grew for early Potatoes in the kitchen garden immediately adjoining the orchard were quite sound. Such manure as we used for the orchard crop was well rotted. The fruit trees are quite small and over 20 feet apart. I should be glad if you can advise me what to do this year.

J. C. CHANCE.

[We think your culture excellent, and do not attribute the disease to any failing in that respect, as upon close examination the skins of the tubers sent are clear where the disease has not affected them, and the disease is mostly at that part of the tuber which is furthest from the surface. Had it been caused by manures, the skin would have been rougher. We wish you had given us the date at which you lifted the crops, as we attribute the failure to the variety, and to the fact that possibly you left your crop too long in the soil after it was matured. As you well know, in the southern parts of the country the drought and heat in July and August were bad for all root crops, and your soil being sandy, you would feel their effects worse than on heavy land. You would, therefore, have done well to have lifted your Beauty of Hebron early in August, and probably you would then have found very little disease; such, at any rate, is our experience. In your case we would advise growing kinds not so easily affected, as there is no lack of good kinds. Probably you lifted your Ashleaf's earlier, but these are not so subject to disease as the early American kinds. We prefer Early Puritan of the American kinds, as it is less subject to disease. If you planted late, that would affect the crop, as the tubers would be matured earlier. We would advise you to change the variety this year and to use a good fertiliser instead of animal manure. Eds.]

CLERODENDRON TRICHOTOMUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR, One is glad to observe that "T." is able, on p. 506, to write a favourable account of *Clerodendron trichotomum* in the south of England. It is one of the plants one would like to be able to induce to flower. It was rather disappointing to have unfavourable accounts of it when I visited Ireland in 1898. One garden in which I saw it was in the neighbourhood of Dublin, and I was informed that it came into bud too late to open before the cold weather arrived. This was a sheltered garden in which many things which are not very successful with us did well. From what one has seen of Irish gardens, one is not very hopeful of succeeding with plants our friends across the Channel cannot persuade to flower. Some parts of Ireland seem ideal places for flower-gardening. I daresay some of the correspondents of *THE GARDEN* in the sister isle will be able to give a more favourable account of the flowering of *Clerodendron trichotomum* in their own or other gardens. One can, however, only speak of what one knows. In this case the knowledge is not favourable to the *Clerodendron*, so that it is a pleasure to have more encouraging information. S. ARNOTT.
Cassloren, by Dumfries, N.B.

SIR, My experience on a dry hill in West Surrey agrees with Mr. Arnott's in Dumfriesshire, that *Clerodendron trichotomum* is not to be trusted as a flowering plant. In the warmest places in the extreme south and west of England it would be likely to do well, but here, though it grows only too rampantly, it does not, within the duration of our summer months, ripen up to flowering maturity. But its near relative, *Clerodendron fetidum*, I find to be an excellent plant for late autumn flowering. During the last five or six years that I have had it growing at the foot of a south wall it has always flowered well; during the last two autumns especially well. Whether this is to be attributed to the heat and dryness of those two summers, I

cannot say, though it seems probable. Each year the established clumps throw the year's growths higher, for, beginning with a height of about 4 feet after first planting, they now attain to 9 feet, with a corresponding size and vigour of foliage.

The flowers are large terminal corymbs of a good full pink colour; in bud they are of a grand crimson. The leaves are large and handsome, and give a tropical look to the whole plant. Their surface, instead of being downy and dull and soft-looking, as in *C. trichotomum*, is bright and polished. They are shaped something like very large Mulberry leaves, the likeness being increased by a bold toothing of the edge, but they have a full, deep colouring that reminds one of the foliage of *Hibiscus Rosa-sinensis*. The only defect of this fine plant is the strong, unpleasant odour given off by the leaves when touched. No blight or insect seems to attack it. During the time of its rapid growth it presents an unfailling picture of prosperous vitality. It spreads quickly at the root, in one season often running 3 feet underground, and coming up in some neighbouring border. G. J.

CYMBIDIUM LOWIANUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR, A *Cymbidium Lowianum*, after making a larger bulb than usual this year, has pushed up two growths instead of flower-spikes. Why should this be? It has been in my possession only one year. The seller told me it had been the same each year and never flowered. It grows in an intermediate house and was kept drier after completing its growth. J. C. WRIGHT.

[It is by no means unusual for *Cymbidium Lowianum* to produce growths when flower-spikes are expected. One may have plants growing side by side all of which have been subjected to the same treatment, yet while some flower satisfactorily others make growths instead. This is more particularly the case when plants of this species are cultivated in the warm intermediate houses or with the *Cattleyas*. When grown under cooler conditions more satisfactory flowering results are obtained, and they rarely fail to produce flower-scapes. The flowers also expand under the cooler conditions and are finer in every way. The warm end of the *Odontoglossum* house is more desirable than the hotter divisions for the culture of *Cymbidium Lowianum*. Under cooler conditions, careful attention will have to be devoted to the watering during the hot summer months. While the plants are in vigorous growth an abundant supply of root-moisture will be required, but towards the autumn and during the dull winter months only give sufficient moisture to maintain the pseudo-bulbs in plump condition. The flower-spikes make their appearance later under cooler conditions. As soon as these are well away from the base, more liberal treatment should be afforded. If the plants are grown in the warmer division, they may be removed in the same manner as *Dendrobiums*, and placed in a vinery or some other cool, light, and airy position for the season of rest. Care must be taken to exclude frost in sharp weather. Eds.]

DOUBLE ROCKETS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, After the appearance of Mr. Arnott's article on the double Rockets I had intended writing about them, but since another Irish correspondent has so fully written, I feel diffident as to giving my small experience. However, I feel I may supple-

ment his instructions as to their propagation by saying that nothing is more simple than treating them in the following way: When the blooms are no longer fresh, cut down all the stems to within 1 inch or 2 inches of the ground; then slightly cover the remainder with a small quantity of bench rubbish, through which the young growths will soon appear. When these growths are from 1 inch to 2 inches long take up the entire plant and pull it into as many pieces as you can. These will all be found rooted, and will make good plants to bloom the following year. This saves all the trouble of spring cutting, which cannot be expected to give the same results, for the drying winds of spring will tell on them more than on those established in the warm autumn soil. No other care do they get here all the year round, and they well repay the small trouble this entails. Here I find

DOUBLE ROCKETS.

they must be dug up and treated as I describe every second year. My garden is on limestone and is of medium soil, which has been well worked and treated for the last century. It would be well if writers in *THE GARDEN*, in describing their successes and their treatment, would give their locality, climate, and soil, so as to guide others, for what suits one garden may not at all give the same results elsewhere. J. HILL POE, Capt.

Riccarton, Ireland.

THE WISDOM OF ROOT-PRUNING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In the article in *THE GARDEN* for December 30, Mr. G. Wythes, in speaking of lifting the roots of Apples, remarks, "It is an easy matter to check gross growth at this season, and by so doing ensure

a full crop next year." This is slightly misleading, for, beneficial as root-manipulation undoubtedly is in necessary cases, it will not achieve this. What root-lifting and root-pruning will do—and the best time to carry out the operation is at the end of October or beginning of November—is to check the next year's growth, and cause fruit buds to develop in readiness to produce a crop the following year. To ensure a full crop next year, one of the chief necessities is for the trees to be furnished at the present time with the requisite fruit buds, and if these are present, root-pruning is unnecessary, that is if a full crop of fruit is secured, as this in itself would check strong growth. Young pyramid trees of Apples and Pears, more especially when worked upon the Crab and Pear stocks and planted upon rich land, are prone to furnish gross wood, and usually need to be root-pruned occasionally to bring them into a free-bearing state; but once this desired state is attained, as a rule further root-manipulation is unnecessary, as the exhaustive nature of the crop generally prevents exuberant growth.

OLD PRACTITIONER.

DOUBLE WHITE ROCKET.

(*HESPERIS MATRONALIS*.)

LIKE many another good garden plant, these fine perennial Rockets can only be grown to perfection in rich loamy soils; even in these they are better for careful division every year, taking off nice side pieces and discarding the woolly centre. They are nearly related to Stocks, and have the same quality of delightful fragrance, at its best and most powerful in the evening. The pure white is the handsomest, but is by no means common. Many people think they have a pure white double Rocket, but it is nearly always tinged with purple; still, this is also a precious plant, and is rather more vigorous and easy to grow than the quite pure white. There is a caterpillar that nearly always infests the flower-bud; it is well to give the bud a careful pinch, such as will crush the maggot, but not the bud.

Coleus thyrsoides.

We have been so long accustomed to regard the *Coleus* simply as a foliage plant, that a species remarkable for its beautiful blossoms is a decided novelty. Such, however, is that under notice, *thyrsoides*, a native of an elevated region in British Central Africa, and which first flowered at Kew in 1898. The blossoms, which are borne in thyrsoid racemes, are of a charming gentian-blue, a tint but little represented among flowering plants at this season. Like the rest of its class, this *Coleus* is of easy propagation and culture, and it is destined undoubtedly to become a popular subject in the near future. The fact of its flowering in January and February enhances its value, supplying as it does quite a distinct feature. H. P.

Pasque Flower (ANEMONE PULSATILLA).

Some people seem to have great difficulty in transplanting this species. There is no real difficulty if the plant is inserted carefully with as much of the slender roots as possible in a deep porous soil, made damp and kept so, a glass being placed over the plant until it forms new leaves. It does better in a calcareous soil than in a sandy one, but I have grown it in both. To make it flower well I supply it freely with water as soon as it begins to start in the spring if the weather is at all dry. —E. M. H.

KITCHEN GARDEN.

CARDOONS.

THIS vegetable is not much grown in this country, and there appears to be less difficulty in growing the plant than in getting it cooked properly, though this should not be difficult with so many good cooks in the country. On the Continent it is valued and made the most of. I am aware the Cardoon is an ungainly vegetable, but the same may be said of many others, and it is an easy matter to cut up one plant into sections, and, treated thus, it would suffice for several meals, as unless Cardoons are large and well grown they are wanting in flavour. As a winter vegetable I would advise more attention to their culture, as at this season there is no great variety in vegetables, and Cardoons, once fully grown, may be kept weeks in a cool, frost-proof place. In the southern parts of the country there is no need to give glass culture at any period, as is generally advised. If the seed is sown early in April in rich land, the plants will make good progress by the end of the summer, provided sufficient moisture is given during the growing season. I prefer to grow the plants in trenches in the same way as Celery, as grown thus moisture is more readily applied and does not drain away so soon. Trenches should be prepared 5 feet apart, and a liberal dressing of decayed manure placed in the bottom and covered over with soil. Seeds may then be sown in clumps of three to five seeds 2 feet apart, and when the seedlings are large enough they should be thinned to the strongest. The culture for the next four or five months consists in giving ample supplies of water, or, what is better, liquid manure in dry seasons. Many sow in pots in April and plant out at the end of May in trenches, and in heavy, wet land this is advantageous, as the plants start away freely. Another mode of culture is to draw drills in richly-manured land and sow in May on an open border.

On the Continent there are many acres of land devoted to Cardoon culture for the large towns, and the plants are grown on the level, but the surface soil between the plants is heavily mulched in dry soils to retain moisture and to feed the plants. When grown on the level there is less trouble in getting at the growths and in keeping the land clean, but in this case it is essential to give ample room to get sufficient soil for blanching, as unless the growths are well blanched the flavour is not so good, and when served the leaf-stalk is less inviting.

The blanching takes place when the plants are full grown, that is either in September or October, the latter being best for the latest plants or those needed for winter use. It is necessary to bind the large leaf-stalk with some protecting material before the soil is placed round the plants. Many use straw or hay bands, and others stout paper and canvas, but whatever material is employed it is well to have it strong enough to bind without cutting the leaf-stalk. After binding, the soil is heaped up to within a few inches of the top of the plants and made firm with the back of a spade. The blanching takes from six weeks to two months, and the plants, being as it were protected with soil, will not suffer from frost if not so severe as to reach the blanched portion. When lifting to shelter we leave the covering on the stalks, and place soil or damp ashes over the roots to prevent shrivelling. There are not many varieties, and the largest are not the best. One called the Pearl is a better type than the large Spanish, the latter, though large, being less white and coarser. Some kinds such as the one named are less prickly than the Spanish, thus enabling the cultivator to work more freely between the plants. The medium growers also need less space.

GARDEN WANTS.

With the advent of the new year the cultivator will need to prepare the seed and root order for the ensuing season. In kitchen gardening, as in every other department, there are new additions yearly, and those who wish to make the most of

the soil will be wise to select stocks that are well known. On the other hand, I make it a rule always to give new things a fair test, as in a year or two some of these will become standard varieties, and without trial their value in diverse soils would not be known. By ordering at an early date one secures better materials, as should some stock be at all short, which is often the case, they are difficult to supply. It is also necessary in some gardens to sow various kinds of seeds in heat for early supplies, and these are needed at this date. Many growers now sow their Onion and Leek seed under glass to get large bulbs, and for frame purposes such seeds as Carrots, Turnips, and Radishes are needed at once. I would point out the importance of occasionally getting fresh seed of Potatoes, as it becomes much weaker if grown year after year in the same soil from one and the same stock.

EARLY BROAD BEANS.

In many gardens this vegetable is more appreciated in June than August, and it is an easy matter to push forward the crop. I prefer pots, although shallow boxes may be used, but with these there is a slight check at planting out. An early variety should be selected, such as the Early Long-pod or Beck's Gem. The latter is small, but very early and prolific, and I have grown it in frames and boxes from beginning to end. Three to five seeds in a 6-inch pot will make good plants for planting out in March on a warm border in light or rich soil, and to promote growth I start the seed in a warm house, and when a couple of inches above the soil remove to a cold frame.

EARLY CAULIFLOWERS.

My earliest Cauliflowers are obtained from autumn sowings, but should there be a scarcity of plants, the deficiency may soon be made good by sowing in heat. There is no lack of varieties. Veitch's Forcing is one of the best, and I have sown this and had it ready for use in less than four months. Those who can give Cauliflowers pot culture will find this an excellent variety, but should avoid much heat at the start. For planting out early in April I usually sow this or Sutton's First Crop in a cold frame, and this lot follows the autumn-sown plants. Sow thinly and expose freely in mild weather. Plants sown in autumn should be given ample ventilation on all favourable occasions, and those in pots showing any traces of mildew should be dusted over with dry wood ashes mixed with flowers of sulphur. G. WYTHES.

NEW AND RARE PLANTS.

LILIUM LEUCANTHUM.

This is one of Dr. Henry's discoveries in Central China. He sent seeds of it to Kew two years ago, describing it as a magnificent Lily with large cream-yellow flowers. A large batch of plants were raised, some of which flowered last year, and proved to be identical with a plant flowered at Kew some years before and which also came from Dr. Henry. Mr. Baker named it at that time as above. It belongs to the same group as *L. longilorum* and *L. Brownii*, but differs from both in its taller stems, the shape of the leaves, and in the size, form, and colour of its flowers. There is every reason for believing that it will prove a first-rate garden plant, as it grew freely at Kew and in a year formed bulbs as large as walnuts. It also has the habit of producing bulbils in the axils of its leaves exactly as in *L. tigrinum*.

HAYLOCKIA PUSILLA.

A FIGURE of this pretty little Crocus-like plant has lately been published in the *Botanical Magazine*, prepared from plants which flowered in the bulb house at Kew last July. It is a native of Buenos Ayres and Montevideo, where it flowers in March, and, judging by its behaviour under cultivation and its near relationship to *Zephyranthes*, it may prove as hardy as, say, *Z. candida*. Dean Herbert,

in whose garden at Manchester Haylockia first flowered, and who named it in compliment to his gardener, Matthew Haylock, aptly described it as having bulb, foliage, capsule, and seed that are scarcely distinguishable from *Zephyranthes*, and a flower like that of a *Colchicum*. The leaves are grassy, 6 inches long, and the erect flowers are 3 inches high, 1½ inches wide, white in one form and sulphur-yellow in the other, with a tinge of red in the throat. The flowers last only about a day, but they appear in quick succession for a month or more.

HELIOPHILA SCANDENS.

This pretty white-flowered climber (illustrated in THE GARDEN, January 13) has been an attraction in mid-winter in the succulent house at Kew for some years (it was introduced from Natal in 1885), and when it becomes known it will probably be an attraction in most conservatories where winter-flowering climbers are appreciated. I may remark, parenthetically, that *Asparagus plumosus* was for many years an attraction in this same house at Kew before its merits as a garden plant were recognised. The *Heliophila* may be likened to the Traveller's Joy in regard to its general effect. It has slender wiry stems, which grow quickly and twine about wires, &c.; its linear-lanceolate leaves are fleshy and from 1 inch to 2 inches long, and its snow-white fragrant flowers are borne in loose racemes. It is not a plant to grow for cut flowers, but it is just the kind of climber which, when planted in a border at the foot of a pillar or rafter, will grow and look after itself, and flower freely and continuously for a month or more in mid-winter. Sir Joseph Hooker says that *Heliophila* and one other genus are the only two climbers in the great order of Cabbages (Cruciferae).

RHODODENDRON KINGIANUM.

A NEW *Rhododendron* from the mountains of Mumpur, a small state adjoining Assam, will be welcomed by the numerous admirers of this genus, and as it will probably prove at least as hardy as *R. arboreum*, it will no doubt in time find a congenial home in Cornwall, where *Rhododendrons* are almost as common as Apple trees. *R. Kingianum* was discovered nearly twenty years ago by Dr. George Watt, who named it in compliment to Sir George King, at that time chief of the Botanical Department in India, and who sent seeds of it to Kew, where it flowered for the first time in the Himalayan house in June last year. Here it has formed a sturdy bush with thick, short branches, crowded, leathery, dark green wrinkled leaves, and compact globose trusses of rich crimson flowers as large as those of *R. arboreum*. Sir Joseph Hooker, in figuring it in the last number of the *Botanical Magazine*, says it is a variety of *R. arboreum*, but for garden purposes it may rank as a good species.

AMORPHOPHALLUS TITANUM.

THE flowering of this gigantic Aroid at Kew ten years ago was an event of exceptional interest, as it was known to be one of the wonders of the vegetable kingdom, the tuber weighing half a hundredweight; the leaf-stalk measuring 15 feet in height and nearly a foot in diameter; the leaf-blade with a spread of 12 feet, and the Arum-like flower so huge, that a man standing upright can barely reach the top of the spadix with his hand, and with open arms he can scarcely reach half-way round the funnel-shaped spathe. Unfortunately, the Kew plant did not survive the strain of flowering, and as it was the only example in Europe, there was no chance of obtaining a fresh supply except from its home in Sumatra. Thanks to efforts made by Mr. Charles Curtis, superintendent of the Penang Botanic Gardens, living tubers were obtained and forwarded to England last year, and some of them were sold by Messrs. Protheroe and Morris. Mr. Curtis presented one to Kew, which, after a period of doubtful vitality, has at last pushed into vigorous growth. There is, therefore, a prospect of this wonderful plant being soon again on exhibition in the Victoria house at Kew. W. W.

RHODODENDRON MULTICOLOR TRITON.

This is a remarkable hybrid, an addition to that interesting group of perpetual-flowering greenhouse Rhododendrons of which so many fine hybrids have been raised of recent years. The latest acquisition is very distinct; the flowers, of a bright salmon-rose colour, set off by a yellowish throat, are produced in a graceful cluster. It is quite a novelty in its shade of colour, and should become as popular as any of its race. From Messrs. Veitch, A.M., R.H.S., January 23.

PHALENOPSIS SCHILLERIANA-STUARTIANA.

This is a beautiful hybrid raised from the intercrossing of *P. Schilleriana* and *P. Stuartiana*. The upper sepal is white, becoming suffused with rose through the central and basal area; the lower sepals white, slightly tinted with rose, the lower halves being thickly covered with rose-purple and brown spottings. There is also some trace of yellow at the base. The front lobe of the lip is white, spotted with rose-purple; the side lobes white, shading to yellow at the base, on which there are numerous brown spots. In the centre at the base there are two prominent raised yellow ridges, which are thickly covered with miniature brown spots. The plant carried a seven-flowered raceme. It is a most distinct and desirable form. Shown at the Royal Horticultural Society's meeting by Messrs. Hugh Low & Co., Bush Hill, Enfield, and given a first-class certificate.

CYPRIPEDIUM SANDERIANO-CURTISII.

This is a distinct addition, a hybrid derived from the intercrossing of the species indicated by the name. The dorsal sepal is upwards of 2½ inches in length; the ground colour creamy white shading to green, thickly and evenly banded with bright purple veining. The petals are each about 6 inches in length, brownish purple, thickly spotted with a darker shade of brown colour. The margins are much crisped, and show the characteristic twist of the *Sanderianum* parent. The lip is upwards of 2½ inches long, showing the influence of *C. Curtisii*, deep brown, veined with a darker shade of the same colour. The disc of the column shows the intermediate characters of the parent species being wholly bright purple. Shown by the raiser, Mr. N. Cookson, Oakwood, Wylam-on-Tyne, at the meeting of the Royal Horticultural Society, January 23, and given a first-class certificate.

EPIDENDRUM WALLISIO-CILIARE SUPERBUM.

This is a beautiful hybrid. The sepals are about 1½ inches long, yellow, suffused with a bronzy tint of colour, the petals being a bright yellow. The lip is upwards of 1 inch across, reflexed, white round the outer margins, becoming suffused and veined with purple through the central area; the ground colour is yellow towards the base. The plant carried a five-flowered raceme. It was exhibited by Messrs. J. Veitch & Sons before the Royal Horticultural Society, January 23, having been raised in their Langley nurseries by Mr. J. Seden. First-class certificate.

CYPRIPEDIUM ACTEUS LANGLEYENSE.

The dorsal sepal of this Orchid is nearly 2½ inches long and of fine form and substance. The ground colour is white except a small blotch of green at the base. A few bright purple spots appear on the white central area, the spottings on the green base being light brown. The petals are greenish yellow with a brown bar through the centre, the base thickly covered with dark brown hairs. The lip is clear yellow on the outside and spotted with brown on the inside. It is derived from the intercrossing of *C. Lecanum* and *C. insigne Sanderi*. Shown by Messrs. J. Veitch & Sons at the Royal Horticultural Society's meeting, January 23, and given an award of merit.

LÆLIA MRS. M. GRATRIX VAR. SUPERBA.

This is a distinct hybrid, raised by the intercrossing of *L. Digbyana* and *L. cinnabarina*. The sepals and petals are about 3 inches long and bright yellow; the lip rather lighter in colour than the other segments and heavily fringed on the margin. This differs from the typical form principally in the colour of the sepals. The intermediate characters of the present species are most prominent in the habit of growth. Shown by Messrs. J. Veitch & Sons at meeting of Royal Horticultural Society, January 23, and given an award of merit.

PHALENOPSIS INTERMEDIA BRYMERIANA.

The sepals and petals of this Orchid are white flushed with rose, the lower sepals spotted slightly with rose-purple; the front lobe of the lip rose, shading to deep purple at the base; the side lobes rose, shading to white. At the base there are tracings of yellow, covered with miniature brown spots. The plant carried a raceme of fourteen flowers and buds. Shown by Messrs. H. Low & Co. at the meeting of the Royal Horticultural Society, January 23, and given an award of merit.

LÆLIO-CATTLEYA CALLISTOGLOSSA VAR. PRINCESS OF WALES.

(*L. PURPURATA* CROSSED *C. WARSZEWICZII*.)

This is most distinct and of delicate colour. The sepals and petals are pale lilac, and the broad lip lilac, becoming suffused towards the centre with rosy purple, veined with a darker shade of purple. The side lobes are rosy purple, shading to white, with some yellow at the base. The finely-grown plant carried eight flowers. Shown by Sir F. Wigan, Bart., Clare Lawn, East Sheen (gardener, Mr. Young) at meeting of Royal Horticultural Society, January 23, and given an award of merit.

CALANTHE REGNIERI HOLOLEUCA.

This is a fine addition to the white section of *Calanthes*. The sepals and petals are of good form and substance and very broad. There is no trace of colour whatever. The plant carried an eight-flowered raceme. Shown by Sir T. Lawrence, Bart., Burford, Dorking (Orchid grower, Mr. White), at meeting of Royal Horticultural Society, January 23, and given an award of merit.

LÆLIO-CATTLEYA CHARLESWORTHII.

(*L. CINNABARINA* CROSSED *C. AUREA*.)

This is a most distinct and desirable hybrid, displaying the intermediate characteristics of the parents both in habit of growth and in the flowers. The sepals are upwards of 2½ inches long, yellow, suffused with orange-scarlet; the petals as long and broader than the sepals and of a deeper shade of scarlet. The lip is much crested, and on the margins deep orange-scarlet, veined and suffused with a darker shade. The plant carried a two-flowered raceme. Shown by the raisers, Messrs. J. Charlesworth & Co., Heaton, Bradford, at meeting of Royal Horticultural Society, January 23, and given an award of merit.

LÆLIO-CATTLEYA SUNRAY.

This is a very distinct little hybrid derived from the intercrossing of *Lælia cinnabarina* and *Cattleya superba*. The sepals are chrome-yellow and upwards of 1½ inches long. The ground colour of the petals is similar to that of the sepals, and suffused with orange-scarlet; the front lobe rich crimson, lined in the centre with a darker shade of colour; the side lobes deep crimson-purple, shading to yellow towards the base. There are numerous purple lines through the throat. In growth the plant is intermediate between the two species. Shown by the raisers, Messrs. J. Charlesworth & Co., at the meeting of the Royal Horticultural Society, January 23, and given an award of merit.

LÆLIO-CATTLEYA FANNY LEON.

This is a very distinct hybrid said to have been derived from the intercrossing of *Lælio-Cattleya exoniensis* and *Cattleya labiata*. The sepals are each about 3 inches long and rosy lilac in colour; the petals as long as the sepals, 2 inches broad, and rich rosy lilac. The broad, fine-shaped lip is wholly of a rich crimson-purple, veined with a darker shade of colour, and margined with white around the outer edges, which are very much crested. The extreme base of the side lobes is white. The base of the throat is prominently lined with yellow and purple. The habit of growth shows the influence of *C. labiata*. Raised by the exhibitor, Mr. H. S. Leon, Bletchley Park, Bletchley, and given an award of merit by the Royal Horticultural Society, January 23.

OBITUARY.

John Ruskin.—John Ruskin, poet, teacher, reformer and philosopher, died at his charming home, Brantwood, Coniston, on Saturday last, in the eighty-first year of his age. Ruskin strived to reach the high ideals preached in his noble moral essays—earnest messages to the world and master-

THE LATE JOHN RUSKIN.

pieces of English prose. His famous works "Modern Painters," "Stones of Venice," "Seven Lamps of Architecture," "Fors Clavigera," "Unto this Last," and "Sesame and Lilies" are amongst the greatest contributions to the literature of this century. On Thursday, in the churchyard of Coniston, Ruskin was laid to rest, in the beautiful country he loved so well. It was his wish, that if his death occurred in London, to be buried with his father and mother in the churchyard of Shirley, near Croydon, the village of which the Rev. W. Wilks is vicar. We leave until next week an "appreciation" of this noble life.

Leaving to others to do justice if they can to Ruskin's genius and its ennobling influence on horticulture as a fine art, will you permit me, under a deep sense of his sudden loss, to cull a sentence or two from the appreciative notice from the *Scottishman* of Monday on Ruskin's influence on art: "In his day Ruskin did more for British art than any other man had done. When his first book appeared, British art and taste were fast bound in the traditions of a poor and vulgar conventionalism. It was in much the same condition as poetry had fallen into at an earlier date, and from which it was raised by Coleridge, Scott, and the other great poets of the romantic revival.

"Ruskin led the revival into the realm of art. He woke the nation into a new and finer sense, and a sense of the true and beautiful in form and colour. He shook the national taste out of its bondage, purged it of vulgarity, and taught it to see and appreciate the beautiful. The revolution of taste that has taken place in the last fifty years has not been wholly his work, but he began it, and even those who now refuse to acknowledge him a master, are the fruits of the stimulus which he gave to the love of art and the sense of beauty.

"The great distinction of all Ruskin's writings is their sincerity, or may be called originality. He drew inspiration from men and books, but he gave us no second-hand work. He describes for us what he has seen with his own eyes—never through the eyes of another. And if this can be said of what he has written about Nature and Art, it is equally true that, whatever his subject, he always gives us his own view of it and his own thoughts about it. Stimulus and inspiration he must have drawn from other masters, but his matter is his own. Nothing higher need be said of work that is so excellent in the main than that none of it is second-hand."

The *Morning Post* says truly of Ruskin "that he wrote with all the exquisite charity and often with much of vehemence of the mountain streams which he loved. To read him is to be infinitely refreshed and to be chilled with a new sense of the loveliness of the English language. Nor is it possible to see a time in the history of our literature when these qualities will not suffice to keep for him a place among the immortals."

How far the revival of gardening as a fine art and a revealer of natural beauty may be attributed to the works and life of John Ruskin, Mr. William Robinson, late of *THE GARDEN*, can best tell us, and in doing so he may be able to lead us all yet higher and further upwards and onwards in gardens of richer beauty, more faultlessly formed by art, and richly and variously filled through the inexhaustible resources of Nature. D. T. Fish.

John Fraser. With the death of Mr. John Fraser at a good old age there is the removal of a somewhat unique, and certainly well-known, personage. He has passed away at the end of a singularly active life, and his name figures in the horticultural annuals for the past fifty years. A member of the floral committee of the Royal Horticultural Society since its establishment in 1858, and latterly one of its vice-presidents, he put in a few attendances in 1899; and if he did not sit at the table, he made a point, as far as his health would permit, in attending the meetings of the society.

The two brothers, John and James Fraser, succeeded their father, who was founder of the business in the Lea Bridge Road, now many years ago. They cultivated New Holland and kindred plants on a large scale, as well as the leading florists' flowers, and at the historic exhibitions held at the Chiswick Gardens up to 1858 they exhibited stove and greenhouse plants, specimen Pelargoniums (show, fancy, and the green-leaved and variegated zonalis), Azaleas, &c., and later in time Roses, though it can scarcely be said they found their way into the front rank. It is currently reported that at one of the great Chiswick exhibitions they, with twenty specimen stove and greenhouse plants, defeated Mrs. Lawrence, of Ealing Park, the mother of the president of the Royal Horticultural Society, and, smarting under her defeat, she bought the whole of the plants, and with them the grower (Mr. May), who forthwith entered her service.

At the exhibitions held under the management of the late Mr. B. Marnock at the Regent's Park, and at some of the earlier ones held at the Crystal Palace, they were prominent exhibitors. At the great international horticultural exhibition held at South Kensington in 1866 they were leading prize-winners with Pelargoniums in several classes, and in the miscellaneous division they staged two dozen large specimen plants, mainly hard wooded, but very few of which are cultivated in these days.

At the earlier provincial exhibitions of the Royal Horticultural Society, which commenced at Bury St. Edmunds in 1867, they were exhibitors, and

also at the exhibitions of the once prosperous Pelargonium Society. The services of Mr. John Fraser were also in request as a judge, and he was one of the 110 censors who made the awards at the exhibition at South Kensington above referred to.

As a valuer and arbitrator in horticultural matters Mr. Fraser's services were in great request, and he invariably appeared to secure the confidence of both parties. He was also a valuer under the London County Council. As the chairman of the Leyton Local Board Mr. Fraser had much to do with the development of the neighbourhood in which he lived; and in course of time the nursery in the Lea Bridge Road was abandoned, and a new one opened in the open district of South Woodford, where a large business is done, especially with greenhouse Heaths, Ivies, Vines, fruit trees, and general nursery stock. The business will be carried on by the son of the deceased, Mr. J. Finlay Fraser.

R. D. Blackmore.—This writer of delightful romances—a writer who has told us of the beautiful Devonshire scenery and its flowers in his tale of "Lorna Doone"—passed away on Saturday last at his Teddington home. The English-speaking world is poorer for the loss of this gifted and interesting man, who hid himself from the world and its gaiety in his garden at Teddington, where he cultivated fruits enthusiastically for

THE LATE R. D. BLACKMORE.

many years. Pear culture was his favourite hobby, and his assistance for many years as a member (then as chairman) of the fruit committee of the Royal Horticultural Society was of importance. We remember with pleasure Mr. Blackmore's paper upon Vine posts delivered some years ago at a conference under the auspices of the Royal Horticultural Society, a paper of practical value, brimful of humour and revealing a deep knowledge of the subject. Lovers of gardens, of scenery, and of healthy literature should read Mr. Blackmore's novels, "Lorna Doone," "Cradock Nowell," and "Perlycross" being amongst his most interesting productions. Mr. Blackmore was born at Longworth, in Berks, about seventy-five years ago, was educated at Blindell's School, Tiverton, and from thence passed to Oxford and to the Bar. "Lorna Doone" shared the fate of many novels as brilliant; it failed to find a publisher until long after it had been written. It is said that eighteen publishers rejected the work, and when it appeared it received scant attention from reviewer and public. Mr. Blackmore attributed the ultimate success of his best known work to the fact that the marriage of Princess Louise and the Marquis of Lorne gave rise to the supposition that the novel was in some way connected with the "Lorne" family. Editions quickly appeared. The public were satisfied, too, if Lorne had nothing in common with Lorna,

they agreed the writer had given to the world a brilliant romance. About ten years after its first publication Messrs. Sampson Low, Marston and Co. issued the 22nd edition. It is not too much to say that Lynton and Minehead were made famous by this novel of the land of the Doones. Mr. Blackmore was a thorough lover of the open air, and besides a keen gardener was a good shot and trout fisherman. Of late years we have missed his familiar face at the meetings of the Royal Horticultural Society, due not to a lessened interest in flowers and fruit, but to failing health.

Mr. Blackmore, we believe, was not offended when described as a "market gardener," and used this *nom de plume* to one of his works. He was an enthusiast, and his produce from the many acres cultivated at Teddington found its way to Covent Garden, but he confessed once to the writer that Pear culture was not all profit.

[The photograph is reproduced by kind permission of Messrs. Sampson, Low, Marston & Co.]

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.*

JANUARY 23.

There was another small, but very interesting meeting at the Drill Hall on Tuesday last, when, of course, indoor flowers formed the chief feature. The orchids were delightful, many groups containing rare species and varieties being exhibited.

FLORAL COMMITTEE.

Before the business of this committee, Mr. Marshall, the chairman, said he had a sad announcement to make. Mr. John Fraser, of the Lea Bridge Nurseries, had died a few days previously, and the Royal Horticultural Society by his death lose a warm supporter on the committee, a member whose knowledge of hard-wooded and other plants was of great assistance in the work of considering the exhibits sent for adjudication. Mr. Marshall said he mourned the loss of a personal friend, and he proposed that a vote of condolence be sent to the family in their bereavement. Mr. Geo. Paul in a few well-chosen words seconded the proposition, and said that Mr. Fraser had been a friend of long standing, and was a man who was ever ready to bring his unique knowledge of greenhouse and hardy plants to bear upon the work of the committee.

A silver Flora medal was awarded to Messrs. Camell & Sons, Swanley, for their group of Chinese Primulas, prominent among which were the graceful Star Primulas, Kentish Queen, The Lady, both white, and Pink Lady. Among them also were Miss Doris, with large white flowers; Swanley Blue; Lutea alba, having white flowers with large greenish yellow centre; The Sirdar, the flowers of which are of a salmon colour. A very pretty mass of colour was formed by this collection. Messrs. Hugh Low & Co. again exhibited a group of Persian Cyclamens, including Papilio and Bush Hill Pioneer, both red and white. This group obtained a silver Banksian medal. A very handsome group of Ferns, to which a silver Flora medal was awarded, was shown by Messrs. J. Hill & Son, Lower Edmonton. We noticed the handsome Basket Fern (*Asplenium caudatum*), with its long drooping fronds; the pretty little *Pelaea rotundifolia*, the very dark and finely-toothed fronds of *Asplenium ornatum*, and also a fine plant of *Cyathea insignis*. There were two bowls of Sacred or Good Luck Lily of China and Japan (*Narcissus tazetta*), belonging to Messrs. Barr & Sons, King Street, Covent Garden. This firm also exhibited a pot of the large *Galantus Elwesii* var. *Whittallii* (figured in *THE GARDEN* last week). Among a stand of cut flowers of greenhouse Rhododendron hybrids, shown by Messrs. J. Veitch & Sons, Chelsea, an award of merit was gained by *Rhododendron multicolor Triton*. This is referred to in our list of new and rare plants. Messrs. Veitch were also the exhibitors of a fine specimen of *Banamelis arborea* (the Tree Wych Hazel), one of the most charming of winter-flowering shrubs. Mr. J. Hudson, gardener to Mr. Leopold de Rothschild, Gumpersbury Park, showed well-grown flowering shoots of the pretty yellow-flowered *Justicia flavicoma*, and was awarded a cultural commendation.

FRUIT COMMITTEE.

There were very few exhibits before this committee. Before the business commenced the chairman made allusion to the death of Mr. Blackmore, who was chairman for a few years. Mr. A. H. Pearson proposed and Mr. H. Balderson seconded that a vote of condolence be sent to the family in their bereavement. We publish elsewhere a portrait of Mr. Blackmore and particulars of his life.

A good even sample of the new Tomato, Winter Beauty, was sent up by Messrs. Sutton & Sons, Reading. This is an excellent variety for winter. The principal feature of this section of the show was an exhibit of fifteen dishes of Apples by Mr. George Bunyard, Maidstone. Of these,

HORMEADS' PEARMAN and NORMAN'S PIPPIN obtained awards of merit. The latter is a small green Apple and is a good bearer and keeper, being fit for use from December to April.

Also in this collection were fine samples of Twenty Ounce, Belle de Pontoise, Farmer's Seedling, Beauty of Kent,

*Plants given first-class certificates or awards of merit are described amongst "New and Rare Plants."

White Nonpareil, Foster's Seedling, Transparent de Crocels, Preston Hall, Improved Ashmead's Kernel, Rambour Papelen, and Chatley's Kernel. Mr. R. E. Davis, Yeovil, Somerset, exhibited six dishes of local Apples; while Mr. J. Chimney, Nevill Court, Abergavenny, had a dish of Apple Welsh Beauty. There was also a dish of the fine Royal Late Cooking Apple, belonging to Messrs. J. Veitch & Sons.

ORCHID COMMITTEE.

As our list of new and rare plants shows, many important novelties came before this committee. Without the Orchids, in truth the meeting would have been small and uninteresting.

Messrs. J. Veitch & Sons, Royal Nurseries, Chelsea, showed an extremely interesting group, consisting of *Cypripedium Harrisonianum* superbum, a very richly coloured variety; a pretty hybrid *Dendrobium* named Dulce, probably a cross between *D. Linawianum* and *D. aureum*; *D. atroviolaceum*, *D. Cassiope*, *Cypripedium Hera Euryades* splendens, very rich in colour; *Laelia Mrs. M. Gratrix*, a hybrid between *L. Digbyana* and *L. cinnabarina*, of a pure yellow colour; *Laelio-Cattleya Pallas*, a hybrid between *Cattleya Dowiana* and *Laelia crispata*, a very richly coloured form; and a very distinctly coloured *Phaio-Cattleya*, of which we shall make further note.

Sir Trevor Lawrence, Bart., Burford, Dorset (gardener, Mr. White), showed a delightful group of rare kinds. One of the prettiest plants was that of *Dendrobium Cordelia*, the flowers of extremely delicate colour, pinky white sepals and petals, the lip marked with deep red; *Epidendrum amplexicaule*, with minute green flowers; *Dendrobium melanoleucum* var. *Rainbow*, the charming *D. barfordense*, *Maxillaria arachnites*, *Cypripedium Lecanum Albertianum*, and *C. Sallierii Hycanum*.

One of the most charming groups of all and containing many well-grown plants was that shown by Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gardener, Mr. Young). It contained several beautiful *Phalenopsis* and *Dendrobiums*. The *Phalenopsis* family is extremely well grown by Mr. Young, especially *P. Schilleriana* and *P. Stuartiana*. Also of note were *Vanda lamellata* and that richly coloured form of *Laelia autumnalis* called *atrobribes* (silver-gilt medal).

An exceptionally fine plant of *Dendrobium atroviolaceum* was shown by Messrs. Sander & Co., St. Albans, the flowers very richly coloured.

That beautiful Orchid, *Laelia aniceps Sanderiana*, came from Mr. J. T. Bennett-Poe, Holmwood, Chesnut (gardener, Mr. J. Bonnes). It was an exceptionally well-grown specimen, *Laelio-Cattleya Cappei (Laelia cinnabarina - Cattleya gigas)* is an interesting hybrid, with yellowish sepals and petals and deep rose-purple lip.

From Lord Rothschild, Tring Park, Tring (gardener, Mr. Hill), came a noble spike of *Odontoglossum crispum* 3 feet 6 inches in length, and bearing thirty-seven flowers.

Baron Schroeder, The Dell, Egham (gardener, Mr. Ballantine), had *Odontoglossum Wilckianum Schroederianum*, a very richly marked form.

Messrs. H. Low & Co., Bush Hill Nursery, Enfield showed *Dendrobium Vanierianum*, a very pretty form, and a pleasing light-coloured variety of *Cymbidium Tracyanum*.

Mr. G. F. Moore, Barton-on-the-Water, Gloucestershire (gardener, Mr. Norris), showed *Cypripedium Mooreanum*, a very richly coloured form; *C. Beckmanii*, conspicuous for its broad dorsal sepal, richly blotched with chestnut, and polished brown petals and lip; also a well-coloured variety of *Cattleya Persevaliana* named *Chardwan* variety, or a similar name, as far as one could judge from the label; the lip is deep velvety purple, very striking against the orange-yellow throat.

Several interesting Orchids came from Mr. W. P. Burkinshaw, West Hill, Hessele, Hull, who showed *Cypripedium nitens Bessle* var., a very attractive flower, and *C. Adrastus* var. *punctatum*, a hybrid between *C. villosum Boxallii* and *C. Lecanum*, a very pretty flower, especially the dorsal sepal, which is green in the lower half, the upper portion white, and blotched with rich purple-brown colour.

Sir William Marriott, Bart., The Down House, Blandford, showed *Odontoglossum crispum* var. *castanum*, a pure white flower with yellow lip, a very charming form.

Cattleya Luddeemanniana Amor Bassall was exhibited by Messrs. Mobbs & Ashton, Southgate, and *Dendrobium Madoune*.

From Mr. de B. Crawshaw, Sevenoaks, came a very finely marked variety of *Odontoglossum Rossi* named *Mrs. de B. Crawshaw*.

LECTURE BY MR. BUNYARD.

In the afternoon Mr. Bunyard lectured upon the "Neglect of Flowering Shrubs."

NATIONAL DAHLIA.

The annual meeting of this society was held recently at the Hotel Windsor. Mr. E. Mawley occupied the chair. The annual report was very satisfactory, and it is interesting to know that at the annual show the number of flowers staged was as follows: Show and fancy, 1302; pompon, 1803; Caetns, 1809; single, 819; with a grand total of 5730. This is not so many as usual owing to the dry summer. In the future the decorative value of the Dahlia will be better shown. Other items in the report consisted of reference to the new varieties given certificates of merit, and the donors of special prizes were thanked. It was hoped that the roll of membership would increase, and, seeing how much interest is taken in the Dahlia, we wonder that this society is not stronger in this respect.

A sad note was struck when reference was made to the late T. W. Girdlestone, who was elected president in 1897, and continued in this office until his death. He was previously secretary for nine years. The catalogue of Dahlias exhibited by the society was his work, and as a raiser of single varieties he was most successful. Truly we miss this good gardener cut off in early manhood.

The income of the society from all sources, including the balance in hand of £15 3s. 9d. from the year 1899, and the

contributions to provide prizes at the supplemental exhibition, amounted to £200 4s. 9d., and the entire expenditure, including the payment of all prizes awarded at the two exhibitions, left a balance of £7 10s. 2d. to be brought forward to the present year.

Mr. Mawley, on moving the adoption of the report, referred to the dry year and the death of Mr. Girdlestone. A memorial to their late president was being instituted to take the form of a specially struck medal, the cost of which would be defrayed by private subscription. In everything relating to the Dahlia it was necessary they should be abreast of the times, and this memorial would fittingly commemorate one who did so much for their favourite flower.

Mr. E. Mawley was elected president, Mr. George Gordon and Mr. W. Marshall being added to the vice-presidents; Mr. Wilkins was elected treasurer in the place of Mr. Mawley, and Mr. J. F. Hudson was re-elected hon. secretary; the names of Messrs. J. Hudson, W. E. Reeve, and J. Stredwick were added to the committee.

No supplemental show is to be held this year, but some arrangement will be made for an exhibition of seedlings, if practicable, in connection with one of the meetings of the Royal Horticultural Society.

The list of Cactus Dahlias annually given in the schedule of prizes was revised, some new forms being added and some old ones struck out. The schedule of prizes was revised and additions made. In future a supplement to the catalogue will be prepared and will appear in the schedule.

IPSWICH DISTRICT GARDENERS AND AMATEURS CULTURAL IMPROVEMENT ASSOCIATION.

A PUBLIC meeting of those interested in horticulture was held in the Ipswich Town Hall on the 15th inst. to consider the suggestion (made by Mr. Close at the annual meeting of the Horticultural Society) that a mutual improvement society be formed. There was a large attendance, most of the local nurserymen and gardeners being present. The proposition to form an association to be known as above was carried unanimously. A committee, consisting of three nurserymen, three gardeners, and three amateurs, was appointed to form rules, &c. Mr. W. E. Close, Holy Wells Gardens, was unanimously elected hon. secretary. Upwards of forty promised to join as members.

ROYAL HORTICULTURAL SOCIETY OF IRELAND.

MR. ANDREW PORTER (gardener to Lord Ashdown, Co. Galway), as the exhibitor who carried off the largest number of prizes during last year at the shows held by the Royal Horticultural Society of Ireland, has been awarded the Williams Memorial silver medal. This medal was placed at the disposal of the council by Messrs. Williams & Sons, Upper Holloway, London.

READING GARDENERS' ASSOCIATION.

The following papers will be read during the remainder of this session: January 22, annual tea; January 29, "Chemical Manures," Mr. F. W. Shrivell; February 13, "Renovation of Fruit Trees," Mr. T. Neve; February 26, "Horticultural Buildings," Mr. G. B. Parsons; March 12, "Hardy Plant Borders," Mr. D. Harris; March 26, "An Evening in a Surrey Garden," Mr. A. Wright; April 9, "Vegetables," Mr. J. House; April 13, "Spring Bedding," Mr. J. B. Stevenson.

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY.

PRESENTATION TO MR. W. BALCHIN, JUNR.

ON the occasion of holding the annual meeting of this society recently at Brighton, an illuminated address was presented to Mr. William Balchin, Junr., from the members of the committee, which expressed warm appreciation of the invaluable services rendered to the society by discharging for ten years the duties of chairman of the committee, and the regrets of the committee that a pressure of business engagements compelled him to vacate the chair. In order, however, that the advantage of Mr. Balchin's business qualifications should not be lost to the committee, he was appointed hon. treasurer. Mr. Geo. Miles, the vice-chairman of the committee, was appointed in his place. It is satisfactory to know that the financial position is satisfactory, there having resulted a profit of over £32 on the year's work, and there is a balance of over £107 at the society's bankers. The society will for the future hold its meetings at the Imperial Hotel, which is much nearer to the railway station, a desirable step, as the attendances at the periodical meetings fell off somewhat owing to the distance of the place of meeting from the centre. The services of the energetic secretary, Mr. Thorpe, were warmly acknowledged by the members.

LINNEAN SOCIETY OF LONDON.

THERE will be an evening meeting on Thursday, February 1, 1900, at 8 p.m., when the following papers will be read: (1) on "Botanic Nomenclature," by Mr. C. B. Clarke, M.A., F.R.S., &c.; (2) on "The Zoological Results of an Expedition to Mount Koraima, in British Guiana, undertaken by Messrs. F. V. McCannell and J. J. Quclch, by Professor E. Ray Lankester, D.C.L., F.R.S., &c.

STOVE AND GREENHOUSE.

DWARF POINSETTIAS.

REFERENCE was recently made to the way in which some growers obtain their dwarf Poinsettias, which are invaluable for small ornamental receptacles in the drawing-room, for furnishing small baskets, or

for use on the dinner-table. The writer states that tops might be taken from earlier rooted plants late in the summer and rooted in the pots they were to remain in. Several years ago I noted having seen a capital batch of plants of this stamp in Norfolk, and that they had resulted from topping other plants, when another correspondent replied maintaining that this method of propagating late batches was simply spoiling one plant to produce another. Doubtless there is much truth in the assertion, as those plants which are deprived of their leads can hardly be expected to break sufficiently strongly at that advanced state to form decent-sized bracts, and thus all the time and labour bestowed on them would be practically lost. Of course, where the dwarf plants referred to were much appreciated, the end will justify the means; but the question is, Could not some old plants, by being kept in very cool quarters, be induced to break sufficiently late in summer to supply cuttings for the production of extra dwarf specimens? I think so, but it would be useless leaving them in a stove till the eyes were pushing into growth. They would have to be subjected to as little warmth as would keep them safe directly flowering was past, and in April moved to a cool north aspect. I think the plants would stand this, provided little or no water was given. Cuttings so formed could be secured with a heel and would root fairly easily. I see no other way by which cuttings could be secured so late in the season. The lowermost breaks are, of course, the most backward. J. CRAWFORD.

GARDEN DESTROYERS.

GARDEN PESTS.

IN reply to "A. D.'s" inquiry, it may interest him to know that in a small garden (about half an acre) I have found the following method effectual in preventing the birds from eating the fruit buds: I get some stiff flour-paste made, and then mix it with powdered bitter apple, and apply with a bristle brush a coat to the fruit buds on a day usually about Christmas-time, and before the buds begin to swell. As a rule the birds attack them after the first sharp frost (which probably sweetens the buds). Currant bushes are best treated soon after the leaves have fallen, as they are attacked sooner than the fruit trees. Possibly white hellebore powder might answer, but I have not tried it.

Bitter apple, or colocynth, as it is called by chemists, is so intensely bitter that no animal will willingly taste it, and it is doubtful even if insects would eat the buds if penetrated by the bitterness. There are two kinds of bitter apple powder sold. One containing the seeds, which is much the cheaper of the two, and the other without the seeds which is used as a medicine. The only drawback to this application is the fact that if there is heavy rain in winter it becomes washed off. In such cases it might be mixed with vaseline, Venice turpentine, or Japanese birdlime, though the last named would make a more difficult mixture to handle unless thinned down with some colza or other oil.

Sparrows are very troublesome in my garden by biting off the tips of the Carnations. The only remedy I have as yet found for this is filling up the tips with soot, which seems to be beneficial to the plants when it reaches the ground. For Primrose and Crocus protection I find nothing better than crossed lines of black thread a short distance from the flowers. E. M. H.

GOOSEBERRY CATERPILLAR AND WINTER DRESSING.

This is a troublesome pest and most difficult to exterminate. For years I was troubled terribly with it, so much so that when I took charge of these gardens, for a year or two I was continually dressing them with some solution, and even then we lost many leaves. I have tried many remedies, most of which only check the pest, and some are worthless. I resolved some five years ago to try dealing with them in winter; accordingly, I re-

solved to dress the bushes with an extra strength of wash which I always apply to the bushes to keep them clean and to prevent the birds from destroying the buds. This is done after the trees are pruned, about the middle of December. This is followed in February by a second dose if needed. At the same time the soil is removed from several bushes right from the stem out as far as any branches extend; this is removed down to the roots and wheeled away. This done, a good dressing of fresh lime is put over the roots and then a coating of manure. This is covered by digging out the soil between the bushes, then the soil from under other bushes is put in its place. These in turn receive a dressing of lime and manure, and so the work proceeds. During the last two years I have had little trouble with this pest, and have not needed to dress the bushes when in leaf.

J. CROOK.

ANSWERS TO CORRESPONDENTS.

Names of plants.—W. G.—1. *Dendrobium nobile*; 2. *Dendrobium bellidifolium*, somewhat distinct variety.—W. A.—1. *Dendrobium speciosum*.—A. E. W., *Dorehyster*, 1. *Blechnum occidentale*; 2. *Polypodium Billardieri*; 3. *P. venosum*; 4. *Asplenium lucidum*.

Name of fruit.—*Mex. Phillips*.—Bergamotted Esperein.

INDOOR GARDEN.

Lapageria infested with scale (J. HEAN). The best and safest method of getting rid of this troublesome pest is by sponging the stems and leaves with a mixture of soft soap and warm water. The plant being a large one, considerable time and patience will be necessary to thoroughly cleanse it, but we feel sure it will be time well spent. When the plant is made quite clean the syringe should be used freely amongst the foliage, as the health and general appearance of the plant is not only increased by it, but green fly and other pests are not so likely to gain a footing when a good use of the syringe is made.

The Guelder Rose (T.). This is not so readily forced as some other hardy shrubs, such as the *Lilac* and *Deutzia gracilis*, for if too much heat is used the display of flowers will be but poor. These latter subjects may be had in bloom by Christmas, or soon after, but the Guelder Rose cannot be depended upon before the latter half of February or in March. Where there is ainery started early in the new year it is just the place for the plants, or they will develop in the greenhouse in a very satisfactory manner. A temperature of 50 to 60 will suit them well. Of course, the plants must be prepared for such treatment, either by confining them altogether in pots, or in the open ground by transplanting each year in order to ensure a compact mass of fibrous roots, which admit of the plant being removed with but little check. It is also necessary that they be grown in a spot fully exposed to air and sunshine, as these conditions are particularly favourable to the formation of flower buds. Besides the common Guelder Rose (*Viburnum Opulus sterile*), the Chinese *V. macrocephalum* and the Japanese *V. plicatum* are also amenable to the same treatment and afford a pleasing variety.

Gloxinia seed (B.). This should be sown as soon as possible, and whether pots or pans are used they must be thoroughly drained. A suitable compost is equal parts of loam and leaf-mould, with a liberal sprinkling of silver sand. To facilitate the operation of pricking off after germination the upper layer of soil should be passed through a sieve with a 1-inch mesh. All being made level and pressed down moderately firm, a good watering through a fine rose should be given, and while the surface is still moist the seeds must be sprinkled thinly thereon. As they are very minute one is apt to sow too thickly, but this must be particularly guarded against. If a space of 1/2 inch is allowed from the surface of the soil to the rim of the pot, it admits of a pane of glass being laid thereon, by which germination is greatly assisted, as it keeps the seeds in a uniform state of moisture. On a shelf in the stove, just shaded from bright sunshine, the young plants will soon appear, when the glass must be at once removed, as the object is to encourage sturdy growth; for this reason they should be kept near the glass and pricked off as soon as large enough. When sufficiently advanced they may be potted into 3-inch pots, and shifted for flowering into those 5 inches or 6 inches in diameter. After their earlier stages the temperature of an intermediate house, or even a greenhouse, will meet their requirements.

ORCHIDS.

Book upon Orchids (J. C. WEBBIT). We would recommend you to watch closely the cultural notes which are given weekly under the "Gardening of the Week" calendars of THE GARDEN. We shall always welcome any inquiries, and will do our best to afford the information required on any particular subject of orchid culture our correspondents may need. We do not know of any work particularly suitable to meet the requirements of a beginner. Veitch's "Manual of Orchidaceous Plants" would assist you; to be obtained from Messrs. J. Veitch & Sons, Chelsea, London.

KITCHEN GARDEN.

Giant Onions (AMATEUR). You seem to be somewhat hitten with the desire to grow giant Onions. These huge bulbs are now grown in almost every garden, so that if you do not at all in haste—and we do not say such—at least you

err in very good company. But whilst with so many vegetables, and roots especially, mere size becomes detrimental to flavour and excellence, in the case of giant Onions not only are great bulbs produced, but these are less hot and much more pleasant to partake of in a cooked state than are those bulbs produced by an ordinary spring sowing outdoors. There are several varieties grown to produce huge bulbs, some of which are not firm or good keepers, however produced, but a true stock of Ailsa Craig, Cranston's Excelsior, the Sutton Globe, or Improved Wroxtan, all globe-shaped, and these are best for the purpose, will, with first-class culture, produce quite giant, handsome, hard-keeping bulbs of the very best description. We have now in our possession superb 2-pound bulbs of Ailsa Craig as handsome as well can be, and hard, and will keep well if desired till the end of March. But these giant bulbs are of great value to produce seed stock, for the plants so obtained always reproduce under any form of culture much the finest of bulbs. You had better secure seed of one of the varieties named or even a couple, and sow it thinly in broad, shallow pans filled with fresh fine soil, in which is mixed one-third of decayed leaf-soil. Gently press the seed in, strew a little fine sandy soil over it, then stand the pans in a frame or greenhouse near the glass and furnish a little warmth. When the seedlings are 3 inches in height lift them carefully and transplant into shallow boxes with similar soil, putting the plants 2 inches apart; water them, and still keep near the glass till early in April, then transfer them to a cold frame where they get ample light and air to harden them. The ground where to be grown should be trenched 2 feet deep and have a liberal dressing of manure put in on to the bottom spit and forked in, then a second dressing on the surface and forked in. Planting out into rows 16 inches apart, the plants being 12 inches apart in the rows, may be done at the end of April, each plant having when put out a good ball of soil and roots attached.

Intercrossing Potatoes (S. W. M.). If you think you can find room for the introduction of varieties of Potatoes obtained by yet further intercrossing, because we have several hundreds of varieties in commerce now, there is no reason why you should not try to do so. Not only is it of no use to trust natural seed-balls, that is to say, seed-balls produced on self-fertilised flowers, but there are very few of the many varieties in cultivation that produce pollen in sufficient quantity to self-fertilise flowers. With very many, especially the heaviest croppers, pollen production is almost nil, and using them as parents often results in failure. Sometimes if such varieties be grown by putting single tubers into 8-inch pots and grown on under glass, thus partially starving the roots, pollen can be more freely obtained. But you can do nothing before June or July. Then in using the pollen-cases of flowers to extract pollen from them on to the thumb nail, rather seek for it at the bases than at the points of the cases. Once get quite a thin film of this pollen-like fine powder on the nail, you will obtain enough to fertilise three or four flowers on some other variety. When those are done pinch off the rest, tie up the truss with a stick, affix to it the nature of the cross on a label, and leave to mature.

Sowing Spinach (DORSET). This leaf vegetable may be sown now, and have successions made up to the end of August, at which time the final sowing to stand the winter, and one of considerable breadth, should be made. To obtain very early Spinach it will suffice to sow rather thickly in rows 12 inches apart the common summer or Flanders variety. So treated it soon bolts off to flower and the plants in the rows are cut clean, stems and all, and so sent to the kitchen. But the best treatment for later sowings, which should be to the end of April, about once in three weeks, is to get seed of the Virolay, or as called here Victoria, sowing it in drills thinly, and when the plants are well up thinning them out to 3 inches or 4 inches apart. In that way very fine stout leafage is obtained. Sowings in May, June, and July, to stand hot weather, should be of the Long-stander and be even wider thinned. This fine thick-leaved variety is longer bolting to seed than is any other. In August sow both the Virolay and the Long-stander. Really, whatever be the names, there are not more than three distinct varieties of Spinach in cultivation, but all these have both smooth and prickly seeds.

GARDEN DESTROYERS.

Scale on Pear tree (T. S.). The scale on your Pear tree is the mussel scale (*Mytilaspis pomorum*), a very common pest, but commoner on Apple trees than on Pears. The easiest way of destroying this pest is by spraying the tree with a caustic wash before the buds begin to open. There are various receipts for a wash of this kind, but the following is the best: Dissolve 1 lb. of caustic soda in a gallon of water, then add 1 lb. of carbonate of potash, commonly known as pearlash, now add 9 gallons of water, and lastly 10 oz. of soft soap which has already been dissolved in a small quantity of boiling water; stir the mixture thoroughly and it is ready to use. The caustic soda should not be touched with the hands, nor be allowed to get on the clothes. The mixture is also caustic, and care should be taken not to get it on the hands or clothes more than necessary, as it is decidedly injurious to them, but at this time of year it will not injure the trees in any way; or the trees may be sprayed with paraffin emulsion diluted with ten times its volume of water, and then with a rough cloth or stiff brush rub off as many of the scales as possible and give another spraying with the emulsion and water. If the tree be trained against a wall, the branches should be unfastened as much as possible so as to allow of the insecticide being applied to their backs; if this be not done it will be impossible to free the tree from this pest. G. S. S.

FLOWER GARDEN.

Diseased Violets (A.). Your Violets are attacked by a fungoid growth. You have probably fed your plants too well. Use leaf-soil and loam by all means, but not too much manure. We think the wood faggots and straw manure may also be dispensed with, and stones or cinders substituted as drainage. The plants should not be lifted into the frames too early.

certainly not before the middle or end of October. They should be firmly planted, as close to the glass as possible, and when once in the frames they can hardly have too much air or too little water—within reason, of course. When the disease first makes its appearance, let the affected leaves be gathered and burned. Then give the plants a slight dressing of sulphur or newly-slaked lime, keeping the leaves quite dry for two or three weeks after this application. The more sun and air in autumn and winter the healthier the plants will be.

Weedy lawn (N. B.).—The surest way to get rid of such coarse weeds in your lawn as Dandelions, Plantains, &c., is to go over the lawn several times and extract the roots as intact as possible. The holes left should be filled up with a little soil, and where the grass is killed, which will generally be the case when the weeds have been growing for a long time, a few grass and clover seeds may be sprinkled on the bare places.

GENERAL.

Seaweed as a manure (S. G.).—Seaweed may be safely used as a manure, and indeed is largely used in many districts bordering on the coast. Its properties are very similar to those of farmyard manure, though it is generally hardly as valuable, containing a greater proportion of water. It is generally gathered from the shore after having been washed up by the sea, but is sometimes cut while growing, and is said to be richer in that condition. Seaweed often contains foreign matter such as shellfish, &c., which have a manurial value of their own on account of the carbonate of lime they contain.

WEATHER IN WEST HERTS.

The past week proved mild and wet. The days were all warm, but on one night the exposed thermometer showed 13° of frost, which is the lowest reading this instrument has as yet registered this year. At the present time the ground at 2 feet deep is about 1 warmer, and at 1 foot deep about 3° warmer, than is reasonable. Rain fell during the week to the depth of about three-quarters of an inch, which is equivalent to 3 1/2 gallons of rain on each square yard of surface. The wind varied greatly in strength, but the direction has ranged principally between south and west. On the 18th the sun shone brightly for over six hours, but during the next four days no sunshine at all was recorded. The Winter Aconite first showed an open flower in my garden on the 23rd, or one day later than its average date of flowering in the previous eleven years, and five days later than last year. An early-flowering Snowdrop I received under the name of *Galanthus Elwesii ochrolepis* was also in flower on the 23rd, or three days later than last year.

Berkhamsted, Jan. 23.

E. M.

TRADE NOTES.

NATIVE GUANO.

We have received a book containing a list of testimonials advocating the use of native guano, and the results of its application in the farm and garden. This good garden stimulant may be obtained from the Native Guano Company, Ltd., 29, New Bridge Street, Blackfriars, E.C.

MR. JAS. WEBBER, for over thirteen years head gardener to Mr. G. F. Luttrell, Dumster Castle, Somerset, will resign at the end of this month to enter business as florist, fruiterer, &c., at Minehead, Somerset.

GARDENING APPOINTMENTS.

MR. LINDSAY CARSTAIRS, late head gardener at Brooklands Park, Halifax, Yorks, has obtained the appointment of gardener to Sir Charles Barrington, Bart., Glenstal Castle, Murree, Co. Limerick.

CATALOGUES RECEIVED.

Tree and Shrub Seeds.—*Johannes Rafn, Skovforhandler, Copenhagen, E. Denmark.*

Chrysanthemums, Carnations, Dahlias, and Zonal Pelargoniums. *H. Shesmith, Clarence Nursery, Woking.*

Manual of Hardy Plants, Seeds, Bulbs.—*Messrs. Kelway & Son, Langport, Somerset.*

Bulbs and Plants for Spring Planting. *R. Wallace & Co., Kilmfield Gardens, Colchester.*

* * * We hope our readers will send their catalogues for notification, and any news likely to interest horticulturists. Their assistance will be greatly valued.

TERMS OF SUBSCRIPTION.

THE GARDEN is sent direct from the Office in London post free, payable in advance. For one year (52 weeks), 15s. 2d.; half year (26 weeks), 7s. 7d. THE GARDEN is also posted regularly to the United States, Canada, the Colonies, and the Continent of Europe, and all places under class "A" of Postal Union for twelve months at 15s. 6d. Postal orders should be filled up to the PROPRIETORS OF THE GARDEN, payable at the General Post Office, London, and should be crossed "London and County Banking Company, Limited."

THE GARDEN.

No. 1472.—VOL. LVII.]

[FEBRUARY 3, 1900.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editors invite readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object they wish to make the "Answers to Correspondents" column a conspicuous feature, and when queries are printed, they hope that their readers will kindly give inquiries the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITORS of THE GARDEN, accompanied by name and address of the sender.

The Editors welcome photographs, articles, and notes, but they will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, they will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editors ask that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editors will not be responsible for the return of artistic or literary contributions which they may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will always be recognised as acceptance.

Edited by MISS JEKYLL and MR. E. T. COOK.

JOHN RUSKIN. AN APPRECIATION.

OF all who have lived and worked throughout the length of the present century there is no one whose influence in matters relating to the fine arts has so thoroughly permeated all who read and think throughout the English-speaking world as this truly great man, who, though for some years retired from the outer world, was till so lately still among the living.

The death of John Ruskin removes from among us a man whose writings and whose personal teaching have undoubtedly been of more effect than any other agency to the awakening of men's minds to a comprehension of the ethical relation of art, not only to the higher human intelligence, but also to the simple needs and experiences of daily life.

Moreover, of all the artists of England who have lived and wrought throughout the length of the century, he is the one who has most effectively encouraged us to endeavour so to see with our eyes and so to receive with our hearts that we may have a more worthy apprehension of the good gifts that are within the grasp of all; of the beauty of flower and leaf, of the sunny smile of peaceful pastoral land, the angry menace of the storm-cloud, the fearful majesty of mountain masses. So he reveals and interprets the moods of Nature and her marvellous structure to minds dimmer and

duller than his own, but eager to receive, and so he tells us of the many ways in which artists of the later centuries have given expression to their comprehension of the Nature-inspired sources of guiding motive, whether in architecture, sculpture, painting or poetry.

In illustration of his teachings as to the reverent and pure-hearted enjoyment of simple natural scenes and objects, we may take one quotation from "Modern Painters," and all the more that it immediately concerns us, as bearing directly on our enjoyment of garden beauty:

"Hence it becomes a more imperative duty to accustom ourselves to the enjoyment of those pleasures of sight which are most elevated in character, because these are not only the most acute, but the most easily, constantly, and unselfishly attainable. For had it been ordained by the Almighty that the highest pleasures of sight should be those of most difficult attainment, and that to arrive at them it should be necessary to accumulate gilded palaces, tower over tower, and pile artificial mountains around insinuated lakes, there would have been a direct contradiction between the unselfish duties and inherent desires of every individual. But no such contradiction exists in the system of divine Providence, which, leaving it open to us, if we will, as creatures in probation, to abuse this sense like every other, and pamper it with selfish and thoughtless vanities, as we pamper the palate with deadly meats, until the appetite of tasteful cruelty is lost in sickened satiety, incapable of pleasure unless, Caligula-like, it concentrated the labour of a million lives into the sensation of an hour, leaves it also open to us, by humble and loving ways, to make ourselves susceptible of deep delight from the meanest objects of creation, and of a delight which shall not separate us from our fellows, nor require the sacrifice of any duty or occupation, but which shall bind us closer to men and to God, and be with us always, harmonised with every action, consistent with every claim, unchanging and eternal."

Those who possess the precious remembrance of friendly personal contact with John Ruskin have their memories stored with an undying recollection of his charming and brilliant personality. All the world knows him as a writer, teacher, artist and art critic, but only the favoured few, those who knew him in his home and daily life, knew how richly he was endowed, not only with an inexhaustible store of sparkling wit, but with the simpler charm of

an almost child-like love of pure playfulness. Even if Mr. Ruskin had taught us no other thing, his inspired words would have made us know, as we had scarcely known before, how to recognise and value the tender tunefulness, the supple serviceableness, the brilliant colouring, the mighty strength, the splendid dignity of our English tongue.

Later we shall hope to touch upon a few of the details of his teaching that bear upon matters more directly concerning our readers; but meanwhile we may remember that the chief aim of Mr. Ruskin's teaching was to search out and make clear to us what in Nature was most wonderful and lovely, and what in the best of man's work was true and honest and good and beautiful.

For some years, to the outer world at least, the eloquent voice has been silent; the hand that held the pen has written no more; the fertile brain has rested from the life-long strain of strenuous labour; but it was good to know that he was yet alive, and living the peaceful life that his weakened health could alone allow, closely tended with loving watchfulness, and within daily view of his well-loved scenes of lake and mountain. But we trust that he knew how many reverently grateful thoughts went out to that quiet northern home from the thousands of hearts that owed him thankfulness, and that feel so keenly that not they alone, but all England and all that wider world that speaks her tongue and shares her literature are the poorer now that he is gone.

FROM OTHER LANDS.

WHILE the days are wintry in England and our gardens can as yet do little for us, we think it well to give a rather larger proportion than has heretofore been the custom of THE GARDEN to letters and illustrations of gardens and of plant life in more southern countries, and especially in those that are most frequented by our countrymen.

Many English people have winter residences on the French and Italian Riviera, that coast so full of natural beauty and so genial of climate, facing, as it does, the full southern sun and sheltered from all northern chill. From Hyères westward in France to Spezzia at the easternmost end of the Bay of Genoa, first the Maritime Alps and then the more easterly range that dominates the whole Ligurian seaboard secure to all this coast-line of some 200 miles a warmer winter climate than even that of Algiers. Many English people also live in Rome and in Florence, some in Algiers, and from these and other winter resorts and their immediate neighbourhood come many of the flowers that are hardy in our gardens.

To name only a few of these, there is the great Asphodel (*A. ramosus*), a plant that, with the noble-foiled *Acanthus*, prevails throughout the whole circuit of the Mediterranean littoral; there is *Anemone apennina*, common at the edges of bushy thickets in the Roman Campagna; there is *Anemone fulgens* of the Riviera Olive yards, and the larger form of the same flower from Greece. From Greece also we have *Anemone blanda*, a near relative of *A. apennina*. Then there are the *Hexes* of all Italy that grow almost as grandly in Devonshire, and even in less badny parts of our islands. There are the *Cistinea* of the southern coasts, *Iris stylosa* and the giant Fennels of Algeria, the many Daffodils of Spain, Portugal, and the Pyrenees, all equally at home with us.

And though we deal mostly with English gardens, we must not forget that garden beauty, and the study and practice that go to its achievement, are not of one country only, but that such knowledge and observation as will help in its purposeful design may be gathered out of all lands. Moreover, it may be a matter of keen interest to many a good working gardener who sees the paper to have clearly pictured in their native plenty and luxuriance these growths of more southern lands that he may perhaps only know as potted individuals in a greenhouse or single plants in a flower border, but can have no other opportunity of seeing as natural masses, conspicuous either for intrinsic beauty or for some important presentment of distinctive character. We shall hope also to show some of the extremely curious and interesting gardens of Japan, another part of the temperate world from whence come many of the best of the plants that are now indispensable in our English gardens.

NEW AND RARE PLANTS.

CYPRIPEDIUM SANDERIANUM HYBRIDS.

WHEN the species *Cypripedium Sanderianum* first flowered, it was thought that the connecting link which had divided the Eastern section of *Cypripediums* and the South American *Selenipediums* had been found. As far as the records go at present this most desired amalgamation has not been effected. On the other hand, *C. Sanderianum* has proved a success as a parent in combination with others of the Eastern *Cypripediums*. It is unfortunate that *C. Sanderianum* is of a slow growth, and this doubtless accounts for its shy flowering character. In 1886 Reichenbach described *C. Sanderianum*, and, as far as records go, there are only five hybrids with this species as one of the parents. In each of these offspring the influence of *C. Sanderianum* has been remarkable, and in every case most distinct and desirable additions have been made. I have no doubt the number will be soon increased, as most Orchid collections have now crosses in a forward state that have been procured from this source. The first to flower among this section of hybrids was

C. SANDERIANO-SUPERBIENS.

It is the result of intercrossing *C. superbienis* (Veitchii) and *C. Sanderianum*. This is by far the best hybrid of the section that has yet appeared, the dorsal sepal being upwards of 3 inches in length, 2 inches broad, and the ground colour white, becoming suffused with purple towards the base, where there are tracings of green; the whole surface is banded with rich purple-spotted lines. The lovely petals are upwards of 5 inches long and about an inch broad, the greenish white ground colour heavily suffused with purple at the base, lighter

towards the apex, the whole surface being thickly covered with rich purple-brown spots, the outer edges thickly covered with prominent purple hairs. They are much crested on the margin, and have the characteristic twist seen in the petals of *C. Sanderianum*. The large lip is wholly deep brown on the outside, spotted with purple on the interior. It was raised in Mr. Norman Cookson's collection, Oakwood, Wylam-on-Tyne, and was exhibited at the Royal Horticultural Society's meeting on August 29, 1893, and received an award of merit.

The second hybrid to flower was

C. PRINCESS MAY.

which flowered in Messrs. E. Sander and Co.'s nursery in 1895, having been derived from the intercrossing of *C. callosum* and *C. Sanderianum*. It is another beautiful addition to the hybrid *Cypripediums*. In shape it reminds one of a superior form of *C. Morganii*. The dorsal sepal displays rich chocolate lines on a greenish white

CYPRIPEDIUM SANDERIANO-CURTISII.

(Shown by the raiser, Mr. N. Cookson, Oakwood, Wylam-on-Tyne, at the last meeting of the Royal Horticultural Society, and given a first-class certificate.)

ground. The petals also have the intermediate characters of the parent species, and are covered with numerous dark brown spots. The prominent lip is wholly of reddish purple.

C. HARRISANUM.

is a secondary hybrid derived from the intercrossing of *C. Harrisianum* (*villosum* - *barbatum*) and *C. Sanderianum*. This is certainly one of the most distinct among the hybrid *Cypripediums*. The dorsal sepal is greenish white, spotted and shaded with deep brown, the lateral one being similar in colour. The long reddish brown twisted petals shade to greenish white at the base, the whole being covered with numerous dark brown spots. The highly polished lip is deep brown, veined with a darker shade of colour. It first flowered in the collection of Mr. Clarke, who exhibited the plant at a Drill Hall meeting of the Royal Horticultural Society.

The next hybrid of this section to appear was

C. MRS. REGINALD YOUNG.

which was raised in Messrs. Hugh Low & Co.'s nursery by the intercrossing of *C. Lowii* and *C. Sanderianum*. It is distinct and pretty, and inter-

mediate between the two species. The dorsal sepal is bright yellow, suffused with rich purple at the base and longitudinally lined with prominent purple bands. The lower sepal is similar in colour. The petals are greenish white at the base, suffused with purple towards the apex, the basal half thickly covered with brownish purple spots. The lip is deep purple, veined with a darker shade of colour. The plant was exhibited by the above-mentioned firm on June 28, 1898, when it received a first-class certificate from the Orchid committee of the Royal Horticultural Society.

The subject of the accompanying illustration,

C. SANDERIANO-CURTISII.

is derived from the species indicated in the name. It is one of the most distinct and charming hybrids of this section. It was raised by Mr. N. Cookson, Oakwood, Wylam-on-Tyne, who exhibited a plant at the Drill Hall meeting of the Royal Horticultural Society on June 23 last, when it was awarded a first-class certificate. The dorsal sepal is upwards of 2½ inches long and about 2 inches in diameter, the ground colour creamy white, shading to green, thickly and evenly banded with bright purple. The petals are each about 6 inches in length, brownish purple, and thickly covered with darker brown spottings. The margins are much crisped and show the characteristic enrlings of *C. Sanderianum*. The lip is upwards of 2½ inches long, in shape resembling *C. Curtisii*, and deep brown, veined with a darker shade of colour. The shield-like disc on the column is most interesting and shows the intermediate characters of the parent species. The habit of growth is robust, the leaves pale green, indistinctly tessellated, and generally indicate the influence of the species used in its production.

H. J. CHAPMAN.

A NOTE ON THE CLEMATIS DISEASE.

A YEAR or two ago you asked for any memoranda on this disease; perhaps these few observations may be of interest. My drawing-room bow-window faces due south. A plant of *Clematis The Queen* grows fast up a rod, but quite in the shade of a *Cupressus stricta viridis* growing one on each side of the steps leading down from the bow-window. The *Cupressus* is 8 feet in height.

I thought the *Clematis* would be better for a little more light, though green and strong, so I trained it out into the open, out of the shade, with care. Next day, after sun, the whole thing drooped from root to crown, and it died down to the base as they always do when stricken. It seemed to me that at last I had mited cause and effect, and set a troublesome matter at rest. For I had indulged in a dream of beauty, and thought how lovely the effect would be of a double avenue of Irish Yews, each straight, 15 feet to 20 feet in height, and trimmed through long years to one stem and a tapering spire, each one draped with a different new *Clematis*.

I acted upon this thought. Behold, thirty or so Yews, each one supporting its frail sisters with its long wobbling canes, stick and brittle critic stems and big labels. Also imagine the critic of the hearth regarding the result with scornful eye, and observing that it was just like my foolish ways to suppose that anything would grow right on the top of a big old root, when all sensible people planted deep in good soil against their house windows, &c.

First year: All started and ran, and my soul swelled with anticipation, when suddenly what is this, and this? Can this be death? Water, water? But no, give up the hopeless task and fall back upon the only hope that the crown may start again from the bare ground. So as I had noticed that the plants went off in sunny weather, I thought that the strain of evaporation must be too great for such hair-like stems, and especially after the experience first told. So after restoring all gaps I watched them all next year and watered vigorously in bright weather. Result: Much the same, a little better, but plainly it was not that. Restored gaps again, built a cement circle round each crown to keep the crown dry, watered as before, but with less belief in the watering idea. Result: Decided improvement, and some of the

trees quite prettily clothed to the top kermesina, Jackmanii, Veitchii, Beauty of Worcester, &c. Restored galls, and filled in all round the crowns with dry sand 2 inches deep, and did not water at all. Result: This year no galls, no disease.

REFLECTIONS ON THE EXPERIENCE.

That no Jackmanii had gone off at all. That all the red Viteellas had gone, over and over, except kermesina, and at last I did not replant them, but must try again now. That the worst are the lanuginosa type, and especially the dwarfest ones. That the disease is caused by fungus which runs on the surface of the soil and rings the stem. That I am not sure of this, because I have seen a stem die off down to a high-up fork. But possibly this may not be from the same cause.

I saw in THE GARDEN last year some suggestions which tended in the same direction as my experiences, and I felt fortified accordingly. Some of the most delicate which I lost steadily till I gave them up for a time may yet fail. I do not know, but I do not think they will when I try them again. That neither sun, nor rain, evaporation, or quality of soil affect the plants, as I thought at first, but bright sun seems to bring on a crisis.

CORRESPONDENCE.

(The Editors are not responsible for the opinions expressed by their correspondents.)

FALSE IDEALS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—All lovers of the beautiful in the garden will have read with a feeling of unalloyed pleasure the leading article on "False Ideals" that appeared on January 20. Long may such sermons be preached in these columns in like unambiguous language, for it is only by the steadfast and continuous upholding of the banner of the true ideal—the ideal that follows the teachings of Nature—that we may hope to stem the tide of senselessly dwarfed and doubled abortions that threatens to banish natural beauty of form from the borders of our annual flowers.

Of old, as may be seen from the portraits of Yandyck and other painters, it was the fashion for every lady of title to be accompanied by her dwarf. Happily, such miserable travesties of "the human form divine" no longer degrade the *entourage* of the fair patrician, and in our flower gardens the artificially dwarfed and the mis-shapen, for the excessively doubled blooms of the present day are but monstrosities, should be treated with a like intolerance, since they are departures from Nature's true mould, and obscure rather than reveal her intentions.

The simple beauty of single flowers is oftentimes hopelessly marred by the doubling process, the precious form being lost in the multiplicity of petals. In the case of the Hollyhock, as stated in the article in question, many of the newer strains are hopelessly spoilt by extreme doubling. Far more beautiful is the Hollyhock of cottage gardens alluded to, where the outer frill of petals has a clear margin on which the moderately doubled centre does not encroach, but still more charming to many eyes are some of the single forms, such as the Fig-leaved Hollyhock (*Althæa trifolia*) with its pale yellow flowers of refined contour.

Tuberous Begonias have, perhaps, suffered more from doubling than any race of plants, many of the blossoms being simply shapeless balls of tightly-packed petals. I was glad, however, to observe at the Temple show last summer that in the best of the newer varieties this inartistic doubling had been considerably modified, and that shapely flowers with a clear sweep of outer petals were well represented.

The old, mahogany-red, single Wallflower, known by Somersetshire cottagers as the Bloody Warrior, formed large branching plants. Stocks may now be met with in village plots 2 feet and more through and masses of bloom, while on the south-western sea-board great *Calceolarias*, often as much as 5 feet in diameter, enlarge their borders year by

year and afford sheets of glowing gold through many weeks of the summer. In these cases each individual plant is a picture, whereas with the much-lauded "dwarf and compact" strains such effect as is possible is to be gained only by numbers, since the plants, singly, lack their natural characteristics of growth to so great an extent as to be merely insignificant spots of colour.

Dwarfed plants are doubtless useful for carpet-bedding, but here we have another "false ideal." Despite the eulogies of the advocates of this style, it is impossible to allow that geometrical figures in crude, flat colours are admissible in any description of garden whatsoever. Not even the meanest flower that blooms should be put to the debased use of forming patchwork patterns, which, bad as they are when composed of inanimate bricks and tiles within the precincts of the house, are infinitely more distressing to the artistic eye when fashioned of living flowers in the garden, where of all places the charm of Nature rather than the tricks of artifice should be studied. Happily, criticism of the carpet-bedding system, thanks chiefly to the author of "The English Flower Garden," is no longer as "a voice crying in the wilderness," for of late years the teachings and suggestions of Nature have been reverently followed in numberless gardens that have, as a consequence, been invested with a restful charm to which they were necessarily strangers in the days of their geometrical floral designs. There remain many, however, where foot-rule and shears still successfully restrain the Earth Mother from revealing herself in her fairest guise.

S. W. FITZGERBERT.

THE DOUBLE ROCKET.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Your illustration and articles about *Hesperis matronalis* interest me greatly, as I have grown the plants somewhat as Mr. J. Hill Poe advises. But the cottage gardener who gave me the first slips showed me what he said was the real old English double Rocket, a much compacter flower-spike, unbranched and close, like a very double Larkspur. This rarer kind appealed more to the gardener's taste than to mine, and I do not know whether he succeeded in growing it. I do not know whether the *Rudbeckia grandicephala striata* described by "T. J. W.," Woodside Park, is to spare, but I would be very glad to have some if he would send a small scrap in exchange for other plants.

R. M. SIMMONS.

One Oak, Chesham, Herts.

STRAWBERRIES FROM SEED.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I should be glad if you would give some information on the cultivation of Strawberry *Jeanne d'Arc* for late use. I sowed the seed last spring, but got no fruit. What I am anxious to know is, if the plants bloom this year, whether the early flowers should be picked off or not, and if so, for how long.

SOLPHINE.

[In reply to "Solphine" we gladly give a few notes on Strawberries for late use, *i.e.*, the alpine varieties. As is well known, there are other means of getting late Strawberries; for instance, plants that have been forced and planted out in June will give a second crop in September and October if well attended to. We have sown seed under glass early in the year and obtained a little fruit from each plant the following autumn, but to do this, of course the best possible culture and also glass are necessary. Seed sown in the ordinary way in the spring will not give fruit the same season, and my best late fruits have been obtained from seed sown in the late spring of the preceding year. Our correspondent names the spring of last year as the time he sowed, and this year should get a very good crop of fruit, and for late supplies it will be necessary to pick off all the flower trusses that show until well into July. Plants on a cooler border give a succession of fruit, but it is not well to grow them on a north border, as the fruit in some seasons fails to ripen, but the latest supplies are obtained from plants on a west border. These when planted are small seedlings, and they should

be denuded of their flower trusses till the date named, and as they are later in showing than those on warmer borders they are more useful.

We have also secured late fruit from runners planted in the spring. These placed out in rich land on an open south border 12 inches apart will give good fruit up to October. The plants do not show bloom so early as the seedlings, but when they do so it must be removed till June or July according to the date at which the fruits are needed. At the same time the plants must not suffer in any way from want of moisture or food, and those raised from runners need more than seedlings. We would advise "Solphine" to give the new St. Joseph a trial for late fruit; it is the best late Strawberry we have grown. This variety is larger than some of the alpine, and runners planted in spring will fruit in the autumn. St. Antoine de Padone is also a very fine perpetual and may be had very late, and so also is Louis Gauthier. These all do well if grown from runners, and are very late if the first flowers are removed. It is usually a safe practice to pick all flower trusses from the plants well up to midsummer and then feed freely with liquid manure till new trusses form.—Eus.]

A NOTE ON *TROPEOLUM SPECIOSUM*.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Four years ago I planted two in a compartment of cemented stone, with a hole for drainage below heaps of crocks, and filled (for *Cypripediums*) with peat and leaf-mould. On each side of this compartment stands a tall Irish Yew, and the roots are cut off from and beneath the compartment.

The whole is on the north side and in the dense shade of a 30-foot *Alicia Albertiana* and no ray of sun can pass. The two started and grew to the top of the 15-foot Yews and flowered gloriously the first year. In the winter I saw my gardener pulling out the dry stems. One he has cleared, the other not touched. I stopped it, and next spring this was the result: The untouched grew and flowered, a pillar of fire; the other never stirred. It was not dead, as there was life deep under ground, so I left it. The flowering one became a mass of blue seeds, and I left untouched both seeds and stems. Next year neither one nor the other stirred, till late in summer some runners started away from one or other crown, and are now, January 20, alive and growing (old roots alive, but dormant).

This seems certainly to show that it is bad to cut the old stems, as they are all alive. Also, probably, that it is wise not to let it over-fruit itself.

H. B.

Ambl. sid.

P.S.—I don't think it cares what it grows in.

KEW GARDENS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—As a countryman to whom perhaps the greatest delight of a visit to town is the opportunity given for seeing the Royal Gardens, Kew, I should like to be allowed to offer my congratulations to the new editors of THE GARDEN on the appreciative tone of the initial article under the heading, "Our Botanic Gardens." My recollections of Kew go back over a quarter of a century, and though I always looked upon it as a garden unique in its interest for gardeners and garden lovers, the improvements carried out during late years have been vast, so that one goes now to see not only a botanic garden in a beautiful situation and of great scope, but a charming garden as well, in which our best plants are well planted and well grown. Kew must have been to many the teacher of how best to group and to grow many beautiful hardy plants, for though a few other private gardens must claim precedence in this work, it was the first and remains the best public garden to popularise these better methods, and I think I am right in saying that simultaneously with this forward movement came better culture in all departments of the huge establishment. Kew now stands as a teacher of how, as well as what, to grow. The special features which have been attained have been well pointed out by you, but those who know Kew know too

that you have by no means exhausted its beauties, and that it will repay the visitor far far more than the cursory "look round" which these noble gardens usually get. CORNISH.

THE NEW ZEALAND FORGET-ME-NOT.

[TO THE EDITOR OF "THE GARDEN."]

SIR, "E. J." in the sub-heading of his paper, published in your issue of 16th September last, on *Myosotidium nobile* (New Zealand Forget-me-not) inserts a mark of interrogation after the New Zealand as if he were in doubt as to the original habitat of the plant. It is not a native of the mainland of New Zealand, but of the Chatham Islands, a small group lying some 300 or 400 miles due east of Banks Peninsula, which lies, roughly speaking, about the middle of the eastern coast of the South Island of this colony. As the Chathams belong to this colony, I think the plant referred to may reasonably have assigned to it the name chosen as the English one. Here we call it the Chatham Island Lily.

I have failed more than once in establishing the normal or blue-flowered form in my garden here, but I have had a plant of the white-flowered variety for several years, and it is still healthy. The blue-flowered and prettier variety does not thrive well in Dunedin gardens, but does excellently on the Otago Peninsula, a few miles away, and I have seen splendid specimens at Port Molyneux, 60 miles to the south, where the winters are more severe than here. I am satisfied that the plant cannot be grown to perfection without sea air. In the Chathams it grows chiefly, if not exclusively, on the coast even within reach of the spray, but a friend who visited the Chathams not long ago informed me that the plant was rapidly disappearing from the islands, being eaten out by stock, and was only to be met with wild in almost inaccessible spots on the coast. Some growers say that the plant thrives best if the soil round it be occasionally sprinkled with a little salt. Probably an occasional spraying with sea water, if obtainable, or, failing that, salt and water would prove beneficial. That this noble plant grows well in some parts of England was evidenced by an illustration you published some time ago of a specimen in a Cornish garden. I am curious to know if it grew near the sea.

Dunedin, N.Z.

A. BATHGATE.

SELECTION OF TREES AND SHRUBS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Would you give me a small list of shrubs and trees, such as Thorns, &c., for a rather windy part near a moor? The soil is rather black, and I have mixed a lot of leaf-soil with it. I should like to know if flowering or evergreen Rhododendrons, Azaleas (we have a lot), and Laurels would do well. J. BEAN.

[Only shrubs and trees of vigorous constitution should be planted in your wind-swept part of the country, and you may rely upon those here mentioned answering your purpose. You say Rhododendrons and Azaleas do well in your locality, which, of course, is a splendid recommendation, as they are capable of producing gorgeous effect when judiciously placed, *i.e.*, having due regard to habit and vigour of plant, colour of flowers, and time at which they are borne. We are not very partial to the Laurel, as it is, like the Privet, a hungry plant and soon robs the ground of its goodness, besides it is frequently cut in bad weather. Barberries would be a success and produce a wealth of lovely blossom in spring and summer and showy fruit in autumn. The purple-leaved variety (*B. vulgaris purpurea*) is not only one of the most effective of dark-leaved hardy shrubs, it is also one of the least fastidious, as it flourishes in barren ground. The best colour effect is produced by plants which have been subjected to hard pruning in early spring. The *Phillyreas* form a small group of accommodating shrubs of compact habit with evergreen foliage. With the exception of *P. decora* (*syn. P. viburnifolia*), all have small deep green leaves and are thoroughly hardy. The Spanish Broom (*Spartium pumica*) is another first-rate shrub for your purpose. The Dogwoods (*Cornus*) flourish in moist situations, and the golden-leaved form named

Spathii is very attractive. The evergreen Oleasters give colour in winter, as the foliage is very bright and constant. The Thorns are delightful spring-flowering trees of medium growth, but require protection from the north and east. The under-mentioned sorts would suit you well. *Crataegus oxyacanthoides flore-pleno coccinea* is the well-known double scarlet Thorn. The red flowers are borne with great freedom and last a long time in good condition. The single-flowered form *pumica* should be planted freely, as a good-sized tree in full blossom is very pleasing. *Multiplex* is a grand double-flowered white variety, and *C. coccinea* from North America is very beautiful in October by reason of the glorious colours assumed by the decaying leaves. The common *Laburnum* is an old favourite, and when in flower few trees are more beautiful. The stronger growing forms of *Deutzia* do well in damp soil. The Bush Honeysuckles are also valuable and tenacious of life. *Pyrus Malus* and its allies should not be passed over without comment, and the Snowdrop tree can be well recommended. Few shrubs are more pleasing than the Lilacs, and some of the later introductions from the Continent are desirable garden shrubs. For damp soil and exposed situations the flowering Currants (*Ribes*) are difficult to beat. *Rosa rugosa* is beautiful in fruit as well as in blossom. It is free in growth and floriferous. The Willows and Elders love damp soils, and cold winds have little effect upon them. —EDS.]

THE SWEET PEA CONFERENCE.

[TO THE EDITOR OF "THE GARDEN."]

SIR, The letter of "Alpha" in THE GARDEN of January 20 last, and others which preceded it, are surely sufficient to prove how absurd it is to convene a conference for the purpose of classifying the varieties into groups of colour and form, &c. Does the Sweet Pea vary so much in form that it is considered necessary for growers and others to meet together to classify them into types, &c.? Surely the individuals who wish to identify themselves with the work of the proposed conference could find something better to do. As your correspondent rightly observes, the Sweet Pea is "a simple garden flower," and if a number of faddists, instead of meeting in conference, as is proposed, would make the best use of the material already available, and work the numerous exhibitions, large and small, throughout the country, encouraging competitions at these shows, a stimulus would be given to the cultivation of named varieties, and the best interests of the flower thereby served. As "Alpha" remarks, the Royal Horticultural Society might institute a trial of varieties, and this should be of a most representative character and quite up to date. Synonymous sorts would by these means receive the attention they merit, and this, after all, is the only good that a conference and trial combined could accomplish. Growers of these beautiful hardy flowers fully appreciate the generous offer of prizes made by the trade and others interested, and if their zeal were directed in the channel above suggested, they would be among the first to benefit as a result of their enterprise. J. DEN.

SIR, The note at p. 46 in THE GARDEN from "Alpha" so aptly expresses my own views of the proposed conference, that I should not have asked for your valuable space if the last few lines of "Alpha" had not touched upon a point that well deserves consideration. I think the promoters of this conference who settled this matter in Edinburgh, ignoring the Royal Horticultural Society, would have done well to have had the conference in that city, but amongst the names of its supporters, I find few who reside north of the Tweed, and I shall be anxious to know when and where the conference will be held, as certainly an outside self-constituted body cannot expect much support from the southern growers. It seems absolutely folly in this age, when there are in truth far too many conferences, to begin one about the Sweet Pea. It is a simple garden flower, and, as "Alpha" properly points out, trials for the purpose of ascertaining whether certain varieties are synonymous may be as well accomplished by the Royal Horticultural

Society as any specially constituted body. I am sure that if it were suggested to Mr. Wilks that the time had come for a thorough trial of Sweet Peas, it would be carried out. S. V.

SAXIFRAGA OPPOSITIFOLIA.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I should like to substantiate your remarks on *Saxifraga oppositifolia* in THE GARDEN of January 20 by the fact that I gathered some just about a year ago close to the summit of Snowdon, overlooking a precipice, which, as everyone familiar with Snowdon will know, probably to his cost, "is often bathed in mist," and just such a place as you describe. I may say that a bought piece is flourishing very well in my alpine garden here, but it has only been planted as yet about fifteen months.

ERNEST LINGFORD.

The Limes, Colthorstone.

THE PROTECTION OF TEA ROSES.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I am sorry to have to disagree with any contributor to THE GARDEN, but Mr. D. T. Fish's comments on Mr. Mawley's views on the delicacy of Tea Roses are so absurd and so incorrect, that I take up my pen to make a few remarks in support of Mr. Mawley's views. I have known Mr. Fish's name as a writer on Rose topics for some years. I do not know him, but I assume that he has been the head gardener in some nobleman's or private gentleman's garden, as I do not know his name either as a nurseryman or an amateur. I have frequently been inclined to write to various garden papers on what Mr. Fish has said in them on the culture of Roses, as his experience and statements have usually been absolutely opposed to the views entertained by some of the greatest of known rosarians. I refer more especially to such men as Mr. Lindsell and Mr. Benjamin Cant, gentlemen whom no one with the slightest knowledge of the leading men in the Rose world can ignore. With Mr. Lindsell's views on Rose culture I am well acquainted, and I may say that in every respect we agree; the essential difference between us is that he is the best amateur exhibitor in the kingdom, and that I can only, with others, play second or third fiddle to him in leading positions. Mr. Benjamin Cant has been the leading professional for over a quarter of a century, and he is both well known and deservedly respected by all rosarians. Both of these gentlemen have frequently expressed to me views in agreement with what Mr. Mawley has written in regard to the delicacy of Tea Roses, and Mr. Benjamin Cant once said to me, "Wait till we have a really severe winter, and then we shall see what want of protection will do to Teas."

We have not had a really severe winter since 1880-81, but the mischief done then was so great, that in the following autumn very few nurserymen could supply Teas. No difficulty at any time has been felt in regard to the supply of Hybrid Perpetuals.

I think I know as much as any other amateur, not more than any other, in regard to the cultivation of Tea Roses, and I grow about 3000 standard Teas. I do not believe in nor do I grow any dwarf Teas, having discarded my last lot of about 1000 this autumn, and I should not dream of allowing my men to leave my Teas unprotected after the end of November: the maiden Teas more especially. The fact in regard to Tea Roses is that there are not six varieties amongst them which are at all hardy, but there are gradations of delicacy also, and I consider amongst the most delicate to be *Mme. de Watteville* (specially named as hardy by the authority of Mr. D. T. Fish), *Mme. Cusin*, *Comtesse de Nadaillac*, *Ethel Brownlow*, *Cleopatra*, *Catherine Mermet* and all her children (well known to rosarians), and Ernest Metz. I could go into this question more fully, and certainly more carefully than I do in this short note, but I write in haste to catch post.

CHARLES J. GRAHAM.

Wrydehands, Leathchead.

THE OLD PALACE AT MATHERN AND ITS GARDENS. 2.

I AM not one of those who quarrel over Nature *versus* formalism in the garden. The sympathetic garden-lover sees nothing to clash in the two principles. Each has its sphere, and the boundary line is not difficult to settle by those who wish peace on earth.

The best of gardening is perhaps to lovingly tend one of Nature's choice spots; to remove what injures, and to heighten what improves its form, to vary and stimulate its flora, to retain the grace and feeling of the wild while adding the eclectic richness and reasoned beauty of the cultured.

But the immediate intrusion haphazard and unprepared, amid the countless curves, the suave lines, the disordered harmony of a bit of broken, woody, picturesque ground of so hard a geometrical unit as a house is apt to give to this latter the appearance of a philistine trespasser in Arcady, and it is generally well to interpose some neutral zone between the two. At the same time, the amount of terrace and formal garden and their character, simple or elaborate, should be in strict accord with the style of the building and the peculiarity of the site.

Here, where no two walls are quite parallel or precisely at right angles; where the original irregularity has been intensified by the entire and partial removal of some, the addition of other portions, and where time has mellowed the lines, the angles and the details, even the immediate surroundings needed a much-qualified formalism. Terraces perfectly balanced, severely geometric, elaborately balustraded would have been as a ring of haughty reproach and conscious superiority to the modest simplicity and amiable license of the dwelling of which they should be merely the supporters.

And so, in the forecourt, though the roadway is sternly straight and stifferly avennued with tubs of tall *Geraniums*, its grass sides are of unequal width, and flanked by rough, vegetation-clad walls of unequal height, one of them quite out of line. And, going through the house, the paved way from the garden door has on one side a little stretch of grass, fitting as best it may into the ruins of the banqueting hall. And on the other side, between it and the west wing building, are beds of dwarf evergreens, Heaths and *Sedums* (relieved by *Gladioli* in summer), which give some variety of form and colour in winter at a point commanded by many windows. Beyond this the wall of the first terrace is the original division between the farm potato patch and the field: 3 feet high only on the former side and not obstructing the prospect. The space within the small enclosure (25 by 40 yards) is, besides the portion above described, laid out in paths, beds, and borders all edged with stone (I found the cobbles which paved the farm buildings excellent for this purpose). Two of the divisions have depth enough for Yews and a few flowering shrubs at the back of the herbaceous plants and bulbs; the narrower ones are furnished with these latter alone. I greatly prefer a stone to a grass edge. The latter either is spoiled by the plants growing over on to it, or spoils the plants by their being cut back to keep it free. But the stone edging may be buried under *Stoncrop*, *Toadflax*, *Sandwort*, *Cyclamen* and a host of humble growths, which also make a carpet for the taller things behind, and may well be allowed to trespass pleasantly over the path.

This garden is entirely open to the sun and air, the far-spreading house sheltering it from all northerly winds. There are no trees to rob the roots and shade the stems, and the plants grow sturdily and yield an abundant wealth of

bloom. Thence we go down four or five steps on to the bowling-green. It rests the eye after the turmoil of path and bed and bloom. Its even surface of turf is carried right up to its low retaining walls, except where it breaks through as a wide Yew-bordered grass walk along a kitchen garden. But against the side where it drops from the upper terrace is a border of Tea Roses raised upon an 18-inch dry wall (over which tumbles a long line of Pinks), and divided

up were they, that the first summer I was here they went nearly dry, as the proper water level was reached by the mud. So I dug out the little upper pond, whose springs, working through the bottom, soon fed it again, much to our inconvenience. But the long middle pond I converted into a canal, a dozen feet wide, by cutting out the banks between it and the upper and lower ponds, by putting a little wattle barrier down the middle and by throwing the

MATHERN PALACE. THE WATER GARDEN.

from the grass by a gravel path along its length. The west wing of the house is also set upon its own little terrace. But here formalism ends, and we descend to the rock garden, where the naturally rapid slope of the orchard is varied and intensified, and through which paths, pushed into irregularity by the contours of the broken ground, dip down to the water garden.

I found three oblong ponds, overhung by pollard Willows, occupying the hollow of the meadow at the foot of the orchard. So silted

yard-deep mud of the one half into the other. The loam of the bank, which I altered into a gradual slope, added to any rough stone, cinder, sand and leaf-mould I could get, solidified this bit of reclaimed land full of humus. I stretched a broad grass path down it with a narrow boggy border for common Flags, Rushes, Forget-me-not, *Mimulus*, and other water-lovers on the canal side, and on the other side a wide gradually rising border, wet at the bottom, dry at the top, and so capable of satisfying the idiosyncracies

of plants with more or less thirsty habits. At the bottom, scarlet Lobelias, Japanese Flags, Rocky Mountain Columbinas, Meadow-Sweets, Rudbeckias and the like flourish in large colonies; above them are deciduous shrubs, *Althæa frutex*, *Hydrangea paniculata*, *Viburnum plicatum*, *Staphylea colchica*, *Spiræas* in variety; and along the top runs a hundred and fifty feet length of varied Michaelmas Daisies, bordered by another grass path, which, being the end of the garden, no one who cares only for plants in bloom need pace except in autumn. The ground about the ponds and on the other side of the canal is little gardened. The Apple and Willow trees largely remain. Quinces, Medlars, and a few shrubs have been added, and the grass is studded with Primroses and Daffodils. Phloxes and a few other perennials, whose bloom the hot sun of the terrace gardens scorches, are being moved down there also. The damp of the ground and the partial shade of the trees give great value to this section of the gardens in the cycle of arid summers which we are passing through. With all our watering the terrace gardens have shown signs of flagging. But the water-garden, with no weary playing of the watering-pot, has flourished exceedingly—moist, luscious, green and restful.

The kitchen gardens have no special feature or great extent, but they have space for a nursery and reserve of plants, and a section for cut flowers, Carnations and Sweet Peas, bulbs and Violets, and, very especially, China and Tea Roses, so that long shoots, with plenty of bud and leafage as well as bloom, may be cut with recklessness, and, wedged in bronzes, carry even into the house the air of luxuriant growth which it is my aim to realise out of doors. This I can only attempt by limiting myself to those sections of plant life, happily numerous, which like my soul. I have to bar the gate to American plants and the whole tribe that fattens on peat and sand, but which here, even with much pains and soil-making, ekes out but a precarious and joyless existence. I have a vision of rock and wood and stream where *Rhododendron* and *Azalea*, *Pernettya* and *Gaultheria*, *Trillium* and *Cypripedium*, and the whole of the desirable Lily clan are revelling in the moist gritty vegetable mould set about amid the mossy boulders by the rushing water's edge, and backed by cliffs out of whose clefts rise the indigenous Yew trees. But to realise this is a future task. I can now only watch the site, with hope mingled with impatience. For the nonce, in a world where time and means are apt to have narrow limits, I have plenty of scope close around me here, and it would be grasping and ungrateful to be much dissatisfied with the results attained.

H. AVRAY TIPPING.

[The photographs for this article were kindly taken by Mr. J. E. Laurence, The Cedars, Cheltenham.]

Jasminum nudiflorum. This beautiful winter flowering climber is in full beauty now in many gardens. It is very welcome at this season, especially when associated with some dark-leaved climber, such as *atropurpurea* or *nigra*.

WOODLAND AND FOREST.

FENCES FOR WOODS.

ONCE heard a proprietor say that the margins of woods should never be of formal outline if good landscape effect were desired; that woods should never be fenced where fences could be dispensed with, and that where fencing was necessary the fencing should, as far as possible, be invisible. These rules have not been observed hitherto, for nearly all the woods in this country are fenced, and often fenced in the most objectionable fashion. Stone walls round plantations are horrors; formal hedges are not

or squares. In many of the pastoral districts of North Yorkshire and Westmoreland, where planting has been done for shelter and ornament combined, this kind of planting is the rule, and many notable examples are to be seen from the Midland Railway between Skipton and Penrith. Within sight of each other I have seen on the sides of the hills at intervals plantations in the shape of squares, circles, parallelograms, and acute angles of various degrees, and the inevitable stone fence round them all. The marvellous taste displayed in the region named has always struck me, and I have often had occasion to go there. I said to an estate agent there one day, "Why on earth do you stick so rigidly to such formal devices?" and his reply was, "Well, I suppose the fields, you see, are mostly square, and they have made the woods to correspond." Owners of estates have usually some taste in such things, and the wonder is that they permit such outrages.

Of all kinds of fences round woods, live fences are the worst, because they never thrive, are most expensive to keep up, and are always formal. I am speaking of estates of considerable size on which the wood fences extend to many miles, the expense of which is great and debited to the woods. I do not know of one single estate on which the live fences of long standing are in good order. The fence is always close to the wood and the shade kills it. The gaps are then mended up anyhow with stakes or wire or loppings stuck in anyhow to fill the gap. Tenants are continually troubling the estate office about their cattle straying into woods, which means frequent journeys to distant points of the estate with men and materials and much expense. What between rabbits on one side and cattle on the other, the getting up of a live fence round a wood is about one of the most futile proceedings I can think of. If a wood cannot provide its own fence, then tightly-strained wire ought to be resorted to. The least objectionable fence for a wood is one made of stout rails with the bark on. It looks rustic, is strong, not expensive, and can be run as close into the wood as desired. One serious objection to a live fence is that ample space must always be allowed between it and the wood, and that means a serious loss of ground to the timber crop. In a wooden fence the posts are the main thing. A man can make

MATHERN PALACE. THE ENTRANCE THROUGH THE RUINED GATEWAY.

much better, and wooden palings are not, to say the least, elegant. Yorkshire and Derbyshire are notorious for their dry stone walls. On some pretty estates, nicely planted for effect, every plantation is surrounded by stone fences about 4½ feet high, or higher, and the effect of such walls seen from the mansion or points of view are extremely bad—stiff, hard, and formal in the extreme, especially in the case of young plantations, in which the trees remind one of cattle penned up in an enclosure. This walling of our woods struck M. Boppe and his companions, French forest officers. "The woods were all enclosed," they said, "and the forester usually carried the key in his pocket." Formality in planting is almost always quite inexcusable, yet many planters or their agents seem to have no idea of planting except in rounds

these in the wood for from 3s. to 4s. per 100, cutting out, riving, and charring at the bottom. If these posts are from 3 inches to 4 inches thick they will endure for a lifetime, provided they are not driven in below the charred line, which should stand 6 inches above ground, otherwise the posts will rot off at the junction with the soil. We use any kind of wood, but prefer Oak or Fir for the posts. As to the rails, it is not of much consequence whether they are straight or crooked; and if they have the bark on, the fence will have a natural appearance that no other fence ever has. In some of the German forests the wooden palings, 6 feet high, against deer, struck us favourably. The materials are got on the spot, and consist of long, smooth Spruce or Scotch Fir rails, such as are never seen in our young woods being

of great length with the bark on and hardly visible. On the approach to the famous Castle of Wartburg the fences are of this kind, consisting of posts, set widely apart, and two or three long Spruce rails with the bark on and smoothly trimmed. The most remarkable thing about these German forests lining public and private roads everywhere is that they are not enclosed at all as a rule. We need fences in this country between woods and pasture fields, but not expensive ones; and fences are not needed on highways any more than on the Continent, where the woods come close to the road. At present the county councils keep the fences on the roadsides, and in many districts these fences about on roads that need no such protection.

Where wooden fences cannot be had, then wire is next best. Annealed, strand, and barbed wire are coming more and more into use, and make a good fence for a wood, especially when strained to wooden posts about 6 feet apart. No kind of fence can be erected more cheaply, and it is easily repaired and lasts long. The wire, or wire rope, staples, and posts are all that are required, and a labourer can set the fence up. Wooden posts are preferable, because they give a better stay than iron, cost much less, and are sooner fixed. Galvanised wire No. 4 costs about 22s. per cwt., and 1 cwt. contains about 300 yards. Annealed wire costs less. The staples cost a few shillings per 1000. In setting up a simple wire fence of the kind suggested, the terminal posts should be strong and well stayed—so, \nearrow inside. That done, a strand put on the top from end to end thoroughly tight, and nailed afterwards to the intermediate posts, will make the framework firm, and then the other wires can be put on. Stays like the above are also needed inside going round curves.

J. SIMPSON.

COLD WEATHER NOTES.

RHODODENDRONS.

THE wind this morning was exerting cold, with a hungry whistle which belied the pale sunrays, which were doing their best to redeem the situation. On such a morning one's thoughts, even before going out, fly to the younger and weaker amongst one's plants, and one's imagination towards devising new shelters, and, if possible, more efficient ones. Creepers are, in my experience, easily protected; either there is a wall against which mats can be laid, or, at the worst, a post that they can be fastened to. It is shrubs out in the open that present the greatest difficulty, nightcaps of sacking or tents of matting not adding exactly to the picturesqueness even of a winter garden.

Our more recently planted Rhododendrons look anything but happy, and I have just been prescribing a good shovelful of nourishment to be laid about the roots of each. It is not, of course, actual protection that they need, for they are hardy enough, but they sicken in this very thin, dry soil, which seems to reach them through their 3-foot blanket of peat.

Even when well grown and long established I must confess that Rhododendrons hardly seem to me to be the ideal thing for these rustling Oak copses of ours. We plant them, of course, partly for their colour in its season, partly because one is sure to need evergreens, and the common ponticum is one of the best of evergreens. But they seem to me to remain exotics, and not altogether happy ones. There are two quite distinct varieties of scenery with both of which Rhododendrons consort magnificently. One is heavy, boggy ground, deep, and dark, and oozy, under large trees, into the con-

crete recesses of which they can settle, and, spreading out in all directions, re-root themselves as they choose in the black earth, their flowers catching the divided sunrays, and turning every hollow place into a pool of colour. Another, and a still more ideal place is a steep hillside, provided that it is furnished with boulders, and provided—*bien entendu*—that the said boulders are not of limestone. There is one such hillside above the Bay of Dublin which I should find it difficult to believe might not be able to hold its own, were it confronted with any similar extent of ground, even amongst the Himalayas. It begins as a stony ravine, rising up out of a rather thin wood. As you mount, the ravine opens up, and the trees fall back. The boulders, with which both slopes are covered, rise higher and higher, and grow larger and larger, till they tower into the air over your head perfect monoliths. In and out, above, behind, and between them grow the Rhododendrons, always enjoyable, but in the flowering season a simple feast of colour, the sort of thing that in a cultivated age pilgrimages will be formed to venerate. To see them in such a place is to get a new impression of the possibilities of heroic gardening. To compare them with the Rhododendron as it is usually grown is to compare Milton with Mason, Turner with the average amateur. Your eyes are caught, your whole mind and spirit swept away upon a tide of colour; the grey micaceous granite of the ravine, the heather looking down over its top, the long undulating river of sky, even the sea below and all its ships, seeming to be merely so many adjuncts and accessories of the central picture.

Such conditions as these, it may fairly be said, are not to be found any day in the week, or in everybody's back garden. We have to work out our own redemption, each of us as we best can, and with such materials as the Fates have lent us. Happily, so far as honest natural conditions go, here in West Surrey the garden-lover, whatever other difficulties he may have to contend with, has much to be grateful for. Thanks to that blessed unproductiveness, so anathematised by Colden, the harrow has literally in many cases never passed over his soil. Its very weeds, as often as not, are of Nature's own introduction, not imported ones. Her handiwork is still plainly visible on every side. She looks up at him out of the Bracken with an aspect not very different from what she wore at the Prime, and if he wishes to spoil her—well, he has to do it for himself! This to many—and, doubtless, excellent—gardeners would seem but a poor compensation for a sadly unproductive soil and a most deplorable lack of any summer moisture. There are others, however, to whom a certain sense of indwelling peace, a certain feeling of underlying harmony, are the very first of all possible requirements. Now both of these are more easily to be found than made.

EMILY LAWLESS.

Hazelhatch, Gomshall, January 15, 1900.

TREES AND SHRUBS.

THE SERBIAN SPRUCE (PICEA OMORICA).

It does not appear probable that many more hardy species of conifers will ever be introduced to this country. The regions of the globe where such species can grow have by this time been pretty well ransacked, except perhaps the unknown parts of China. Still, odd ones keep on appearing. Little more than a decade has passed since this Spruce was first introduced and it is still uncommon. A native of the mountains of Servia, Montenegro, Bosnia, &c., it was first discovered

by Dr. Panic. Judging by its behaviour up to the present time, it is likely to prove one of the most useful and quick-growing of the Spruces, several of which do not thrive well in many parts of this country. It is a distinct species, and although a native of Eastern Europe, its nearest ally (*Picea ajanensis*) comes from Japan. Its habit is slender and pyramidal, and in its adult stage is said to equal the common Spruce in bulk and stature. Its leaves are $\frac{3}{4}$ inch long, and marked with two blue-white lines on the upper surface. The young branches are clothed with short black hairs. At Kew young plants raised from seed increase in height at the rate of 1 foot to 18 inches yearly. To those interested in conifers this Spruce may be recommended as worthy of notice. It is offered in the catalogues of several firms.

W. J. BEAN.

Kew.

CANDLEBERRY MYRTLE.

Will the editors kindly furnish the botanical name of a flowering shrub which is locally called Canterbury Myrtle? It has small bushy leaves 4 inches in length, growing like a tuft at the end of the branch. Underneath the leaves it has dark seeds like a bunch of peppercorns. The shrub is highly aromatic. It grows about 4 feet in height.

Tijshire, N.B.

S. BERRY.

[The shrub is the Candleberry (not Canterbury) Myrtle, or Candleberry Gale, of the Northern States of America, an ally of our native Bog Myrtle or Sweet Gale, with larger leaves of still stronger and better fragrance. This good shrub should be in every garden, for, though not of conspicuous beauty, the delightful aromatic scent of a leaf crushed in the hand makes it a source of much enjoyment. It is most at home in boggy, peaty ground, but will do well in drier places in peat or in sand and leaf-mould. The botanical name is *Myrica carifera*. Ebs.]

CUPRESSUS MACROCARPA LUTEA.

WHERE the Monterey Cypress flourishes, its golden-leaved form may be planted also. For decorative planting in the western and southern counties, *C. macrocarpa lutea* is well adapted. In habit it resembles the type, but its general effect is much superior. As a lawn specimen it is effective, and if well exposed to the sun the golden-coloured leafage is intensified.

CHIMONANTHUS FRAGRANS

THE Winter Sweet, as this is frequently called, is a cherished wall garden shrub, and although received from Japan upwards of 130 years ago, the number of specimens to be found in these isles is by no means great, the reason no doubt being that it is difficult to propagate. It may, however, be increased by layering in autumn, and plants favourably situated sometimes bear seed from which young plants may be raised in quantity. It succeeds best in turfy loam and leaf-mould, but abhors anything like stagnation at the roots. Although perfectly hardy and suitable for planting in the mixed shrubbery, it is advisable, but not essential, to train it against a wall, as it is then afforded protection from cold winds at flowering time. The small, deliciously scented yellowish flowers, stained with purple on the inside, are produced along the leafless twigs about the middle of December and remain objects of admiration for about two months, and will, if severed from the plant and placed in a little water in shallow saucers, keep fresh for a long time in the dwelling-room. The variety named grandiflorus is more vigorous than the type, the flowers larger, but the fragrance emitted is not so powerful. A mistake in the culture of these charming shrubs is that they are too often left to take care of themselves. This is not as it should be, as immediately the flowering period is past, pruning should be attended to. Remove the worn-out shoots and cut back the lateral growths, the object being to encourage as much young wood as possible, as it is upon the wood made during the previous growing season that the blossoms are borne in winter.

WORKERS AMONG THE FLOWERS.

ROSE HYBRIDISATION AS PRACTISED BY THE LATE LORD PENZANCE.

(Described by his Gardener.)

IN contributing this short account of the work done and the methods employed by my late master I cannot help feeling that the task should rather have been allotted to someone who was better able to put into words the devotion to the queen of flowers of him whom King Death has recently taken from our midst, and who was a just and kind master to all who served him faithfully.

It was a few years before my engagement at Easing Park that the late lord turned his attention to the Sweet Briar (*Rosa rubiginosa*). Being attracted by its vigour and admirable perfume, he thought how much more attractive it might become if by some judicious crossing the flower could be improved and the scent of the foliage retained. Obtaining plants of the Sweet Briar in pots, he commenced operations, not only by fertilising the Sweet Briar with the pollen from the various Roses, but *via versa*, inoculating the Hybrid Perpetual with the pollen of the Briar. In the first batch of seedlings very few crosses were found, and upon close examination of the Sweet Briar blooms the following season it was observed that unless the anthers were taken from them very early in the morning, they burst and the pollen was shed, all blooms being in consequence self-fertilised. Buds were therefore cut open and prepared for the hybridist long before bursting, and all possibility of their becoming self-fertilised prevented. Thus the road was paved for success, many crosses being visible in the next batch of seedlings. But it was not until the tiny plants became well established that any weeding out could be attempted, as it required an experienced eye to detect the slight variation in foliage or spine in the early stages. Well do I remember cutting the bloom from the first cross, which resulted from pollen of an old Hybrid China Rose named William Jesse.

From that time onward frequent were the rewards of perseverance and patience. Many crosses resulted from the Hybrid Chinas. In the Hybrid Perpetual the most successful as a pollen parent was *Souvenir d'Anguste Rivière*, from which almost all the dark coloured varieties of the Hybrid Briars owe their origin. The Scotch Roses, *Rosa lucida*, and the Persian and Austrian Briars also played an important part. Many also were the crosses made from various Teas and Noisettes, but in no case was it a success: the hard glossy foliage and rambling habit were often produced, but no advance in flower was gained. That race, in consequence, was in future left to itself.

I should here mention that the crossing of the Hybrid Perpetual with the pollen of the Sweet Briar showed but very little result, the seedlings having no scent and but very little

vigour, while the flowers were reduced in size and slightly spotted or striped.

The next taken in hand was the species *camelliaefolia*, but here considerable difficulty was found in getting a sufficient supply of pollen; but having given the plants a good baking in the sun, the following season flowers were much more abundant, and a good supply was obtained. The idea was to transmit the glaucous foliage to the Hybrid Perpetual, so that it might be made better able to withstand the ravages of that arch-enemy, mildew. On this attempt *Dame Fortune* did not smile, for though several crosses resulted, only two could be said to carry the foliage satisfactorily, and

some very fine Roses resulted, but in most cases they proved to be summer flowering, and were almost, if not quite, identical with the race of the old Hybrid Chinas. These have great vigour and hardiness. The Musk Rose did not escape, and by its use some beautiful garden Roses were obtained, one of these, a cross from *Princesse de Nassau* with *Isabella Sprunt*, being one of the finest garden Roses I know, growing into bushes 8 feet or 10 feet in diameter, and covering itself with flowers of a creamy white colour, the flowering season extending until late in the autumn. It is extremely hardy, a fact which is surprising, as both parents are decidedly tender. Several other crosses from

similar plants are all more or less beautiful, being of a climbing or rambling habit and covering themselves with flower.

Rosa rugosa was early in the field as a seed parent, and I have no doubt that many beautiful Roses, both single and double, may be had from this source; moreover, in all cases that have come under my notice the progeny is, as our friends across the Channel say, truly *remontante*, and sufficiently hardy to withstand our varying climate. Hybridists would do well to give attention to this race.

Many Hybrid Teas have resulted from this crossing, some of very lovely and uncommon colours, and in all cases they proved quite as hardy as the Hybrid Perpetuals. In one case that must not be overlooked the yellow Persian Briar was used with Hybrid Perpetuals with a view to transmitting its colour. Many seedlings resulted from the combination, but among them were many disappointments. These showed the spine of the Briar and foliage almost identical, though slightly enlarged. Others having the Hybrid Perpetual as seed parent were sadly wanting in constitution, and their flowers, all but one, were very poor, being of a peculiar ragged form and tawny hue. The one exception was from a summer Rose, *Catherine Bell*. Here was a poser, as both parents are summer flowering and strong growers. This seedling proved to be of medium growth and as perpetual flowering as one could wish to see, the colouring of the flower varying from pale yellow to a deep rosy pink, and often blending into a most lovely hue. Such are the vagaries of Nature! The work enlisted the service of many other varieties, but I have only mentioned those that gave the most interesting results.

And now for a few words as to the care and work needful for the welfare of the seed plants. As all hybridisation was carried on under glass, the greatest care was taken to avoid confusion; each bloom operated on was carefully labelled with the name or number of the pollen parent and the date of the operation, the same being recorded in a book kept for the purpose, with a note on the state of the weather at the time. No brush was ever used for the application of pollen, or anything that could possibly convey admixture of foreign matter. No blooms bearing anthers were allowed in the seed house, and the ventilators were carefully

THE LATE LORD PENZANCE.

most of the others were lacking in constitution, being spindly and extremely tender. One plant that resulted grows strongly, carries the foliage well, and bears a white flower, fully double but small, and though some seven or eight years old has not shown any signs of being attacked by either mildew or rust.

The Sweet Briar was next crossed with the Moss Roses and several mossy varieties obtained, but of a constitution less robust than that of the others. Many other varieties were tried, but more as chance experiments and without aiming at anything definite. I will here mention a few of the chief sorts dealt with. Many were the crosses made between the old Gallica Roses, the Bourbons and Hybrid Perpetuals. From these

guarded to keep out insects. All the work was planned and carried out with that method and forethought that were characteristic of him who has passed to that bourne from whence no traveller can return. G. BASKETT.

NOTES ON WINTER FLOWERS IN ROME.

JANUARY, 1900. It is winter in Rome. The *padrona*, with a significant twist of the shoulder, greets us in the morning with "*Brutto tempo*" (nasty weather), and we return the greeting, secretly wondering at the unlooked-for aspersion on the weather. Looking out, we see the tall Eucalyptus opposite swaying and tossing its light branches. A slight hoar-frost whitens the grass in the moisture-laden corner of the Borghese Villa, which we overlook. A *Ricinus* rears its noble crimson stem and broad palmate leaves just below our windows. No sign here of winter's grip: the day is brightly beautiful. Under foot, when we go out, the tufa-paved street is dry and clean; overhead, the sky is serenely blue, and the sunshine is deliciously warm. We turn the corner. Ah! now we draw our wraps closer, for the icy *tramontana* meets us, and sends a shiver through every limb. Yes, truly it is winter in Rome! Men throw their heavy warm cloaks over their shoulders; women, bare-headed, gather their scanty knitted shawls about them, for in winter weather Italians look intensely miserable and "shrammed," as the Dorset word goes; but the *forestieri*, in warm furs and thick garments, are supremely happy, and go by chatting and laughing.

At the top of the Spanish Steps we pause to look over into a garden. A white scented Jasmine in full flower and bud clings to the wall; a Camellia shows its waxy rosettes; and Oranges gleam amongst their shining leaves. A group of Date Palms stands out in relief against the clear sky, and an Abutilon hangs its buff-coloured bells over a neighbouring parapet. A lovely, unknown evergreen bush arrests the eye, and we make a mental note of it for future investigation. This, also, is winter in Rome, and we need not grumble at the keen blast when Nature is so kind.

For all that, Rome, in such matters, scarcely makes the most of her opportunities. At the foot of the lovely old steps, with their curved balustrades and broad platforms, the flower-sellers have grouped their basket stalls round the edge of the quaint *Bacaccia* fountain. What masses of bright colour they display! Roses everywhere—magnificent Roses, too—*Maréchal Niel*, *La France* (or a near relation), *Safrano*, *Marie van Houtte*, and many more. These are arranged in tasteful bouquets of one variety only, cut with plenty of foliage and fairly long stems, assisted, however, as we find when we begin to muddle them, by pieces of stick. And not Roses only. Brilliant, many-hued Carnations, double Neapolitan and deep blue *Czar* Violets in huge bunches, Paper-white Narcissi and yellow Marguerites, and a host of others crowd the stalls. Who could guess, with such a home climate, that these have been imported all the slow way from the Riviera, through countless tunnels, reeking with a sulphurous atmosphere which might safely be warranted to creep into the most carefully packed box or basket, to grace in such dewy freshness these Roman stalls for the *feste* of Christmas and New Year!

A gardener's eye seeks instinctively amongst the florist's flowers for something more local and characteristic: and, in welcome profusion, on some of the stalls, big bunches of an old garden friend, *Iris stylosa*, are to be found. Chary of its favours sometimes in English, or

shall we say, Welsh gardens, here in Rome it is evidently quite at home, and free enough to be grown as a market flower. These, cut in bud, may be bought, by the wise, before they expand, and then last many days in water, in spite of their delicate, fragile beauty; but, alas! for those who prefer the soft blue of the tempting open flowers.

Another notable feature, giving a characteristic touch, is the framing of the wicker stalls in drooping sprays of Eucalyptus and Mimosa (*Acacia dealbata*). Several species of Eucalyptus are used, one especially beautiful, with ruddy reflections from the crimson leaf-stalks distinctly tinging the long grey-green foliage. Eucalypti are just now bearing creamy wheel-shaped flowers, together with their crinkled seed capsules, and branches of these, mingled with the soft cascades of Mimosa tassels combine to make a worthy setting to the gay blossoms below.

Apròpos of the transit of flowers, it took one by surprise lately to read the following statement in Signor Lanciani's delightful book on "Ancient Rome," which is given verbatim, as it may be of general interest. It refers, be it understood, to the days of the emperors: "The Roman flower—the flower *par excellence*—was the Rose. So excessive was the demand for Roses in the cold season, that to supply the requirements of the market, and to meet the deficiency of native production, they were imported from Egypt. Means were employed, of course, for keeping them as fresh as possible during the journey." This excites one's curiosity. What means were employed, and what the duration of the voyage! But Roman gardens and greenhouses of those early days are no myths, and present a subject of deep interest, and one as yet scarcely touched upon.

Butcher's Broom, well set with large scarlet berries, supplies in Rome the place of Christmas Holly. This is a species of *Ruscus* much to be commended to the notice of English gardeners. Acclimatised, it would be a precious addition to our woods and hedges. It is near akin to our British *R. aculeatus*, but is more elegant in growth—the leaves larger and less densely set on the stems, and the handsome berries, freely produced, are about the size of an ordinary marble. It grows abundantly in the high country about Siena, which would seem to indicate tolerable hardiness. Together with the *Ruscus*, the peasants bring in bundles of a pretty and distinct wild Asparagus, which has the property of lasting for weeks out of water, and is useful in certain kinds of floral decoration where long trails are desirable.

Flowers are not particularly cheap at present, but in November one could decorate a room with yellow, white, or bronze Chrysanthemums, or delightful little bouquets of pink or crimson China Roses and greenery for a few *soldi*. Amongst notable flowers in late November there appeared for a brief season in flower shops and at street corners long stems of *Dahlia imperialis* hung with pale drooping bells. Impossible to flower out of doors, except under genial skies, yet how grandly beautiful it is! Snowdrops, taking time by the forelock, began early in December and are still fresh and fair. A few Christmas Roses are occasionally to be seen, and the first early Anemones of the coronaria section are coming in, but look rather as if they had taken a short cut and had arrived too soon. K. L. D.

PLANTING ROSES.

No time should be lost in bringing the planting of all Roses to a close. The recent sharp spell of wintry weather postponed much planting—in some parts at least for a month. Now that the soil has again got into a workable condition, no time should

be lost. There is no doubt whatever but that early November planting of Roses is much the best plan. The soil at that time retains some of the summer warmth: the consequence is, roots are at once formed even if the plants themselves appear quite dormant. At one time I was somewhat sceptical as to the autumn formation of roots, but now I am not. I know quite well that root action is brisk even in December with newly-planted Roses. E.

NATIONAL ROSE SOCIETY.

THE TROPHY CLASSES.

THERE can be no doubt, I think, that Mr. Charles J. Grahame has given the National Rose Society a somewhat hard nut to crack, and as he appealed to me, I think it only fair and courteous to give my opinion on the matter. That there is a foundation of truth in the statements that he makes is, I think, unquestionable. When one exhibitor carries off the trophy eight times in the last ten years, other competitors must feel that as long as he is in the field there is very little likelihood of unhorsing him, and that this is the prevalent feeling, I conclude, from two reasons: First, that before that period the trophy was often carried off by amateurs whose gardens were much smaller than those of the present winners of the prize. There may have been, of course, exceptional causes in the character of the season that may have accounted for this, but I note that, whatever be its character now, whether it be an early or a late one, a wet or a dry one, Mr. Lindsell is sure to carry off the coveted trophy. The season of 1899 is a remarkable instance of this. A week before the metropolitan show he told me that he did not think his flowers would be in, but they were, and as much superior to the other competitors, as usual. The other reason why I think the statement well founded is, that there are growers—some of them in Mr. Grahame's own neighbourhood—who, I think, ought to be able to put in a good appearance in that class, and it is just possible that it is this feeling that keeps them back. But the difficulty arises when we have to decide what course to adopt. From one point of view Mr. Grahame's proposition is an easy way of solving it; but then would the trophy be a champion trophy? If the probable winners were to be excluded, it would surely take off from the honour and glory of winning it, and it could hardly be called a champion class. Moreover, those excluded might resent the exclusion and say they would not exhibit at all, and we should lose some of the best flowers likely to be shown at the exhibition. Time is often a solver of many difficulties, and as nothing probably will be done in a hurry, the matter might be well talked over at some of our meetings, and careful and deliberate opinions formed as to the best course to be adopted. I need hardly say that, in whatever way the difficulty may be solved, I shall be very glad to give it my earnest support. I know that Mr. Grahame's motives in making this suggestion are quite disinterested, and that his sole object is the prosperity of the National Rose Society. H. H. D.

Winter Aconites (ERANTHUS HYEMALIS).

Amongst a large colony of this beautiful little winter plant there is one small patch in my shrubbery the flowers of which are of a distinctly paler shade of yellow than all the others; indeed, they might be considered a sulphur. I should like to know if such a variation is common, and if so, whether it has been established. I went carefully through the gardens of St. John's College, Oxford, where there must be nearly an acre of these flowers beneath the trees, but could not find any of this pale shade. The gardener there, in answer to my inquiries, told me that he had never noticed any such variation. I carefully removed my little clump last year to a different part of my garden, so as to preserve the integrity of the seeds, and I am glad to say it is thriving and the blooms come up true to their pale colouring. If such a shade of colour could be established, I think it would be a great gain, as they are very beautiful. I would forward one of the blooms to you for inspection were I not very anxious to secure all the seed can possibly collect. G. D. LESLIE.

AN ARTIST'S NOTE-BOOK.

AN IRISH CHRISTMAS ROSE.

THE accompanying sketch gives a charming idea of one of the best of all the so-called Christmas Roses, viz., *Helleborus niger* var. *invernus*. It is recognised by its shapely pure white blossoms being borne on long stalks of a clear apple-green colour without any red or purple dotting whatever. The leaf-stalks are also clear green and unspotted, while the leaves themselves have leaflets with their margins but very slightly serrated. I originally described this distinct form in THE GARDEN as St. Brigid's Christmas Rose, it being quite different to Miss Hope's variety, which the late Mr. McNab called *H. niger* var. *angustifolius*. There is a legend that the late

dare, and was so fond of them, that she reared more than one batch of very fine seedlings. These were from *H. n. invernus*, or St. Brigid, as the seed parent, the pollen used being from blooms of good varieties obtained from England by post. Of the first batch of forty-two seedlings all were more or less different, but none were absolutely superior to the mother parent. Seed grows very freely sown as soon as it is ripe, and the seedling plants grow very rapidly and are at their best from the third to the fifth year.

There are besides these numerous other seedling forms or varieties of *Helleborus niger* some imported from wild habitats and others reared in British and Irish gardens, but the best of them are *H. niger maximus* (*altifolius*), *H. n. Riverston*, *H. n. Mme. Fourcade*, *H. n. Apple Blossom*, *H. n. St. Brigid*, *H. n. angustifolius*, and *H. n. Bath major*. All these are very beautiful as well grown, and flower at different times, so that they yield a succession

of evergreens when successfully grown. If not perfectly happy either in relation to their position or with regard to soil, not only do the leaves die off prematurely, but all the *Hellebores* of the *H. niger* section are peculiarly liable to the attacks of fungoid disease. On both peaty and loamy soils in England and Ireland I have seen clumps of the *Riverston*, *St. Brigid*, and *altifolius* varieties 4 feet or 5 feet across perfect masses of healthy leaves and snow-white blossoms. Small plants may be protected with hand-lights or cap glasses, and in this way the blooms develop cleaner and better than if exposed to wind and rain, but now and then I have seen plants from five to ten years of age that could only be sheltered by a two-light frame.

No other hardy plant I know, not even the blue or white *Iris stylosa*, can give such a profusion of flowers during November or December and January as does a well-grown bed or border of the best of Christmas Roses.

So far as my own experience goes, the present season has not been a very good one for these *Hellebores*, the flowers being dwarfed or stunted-looking, and this is, as I suspect, owing to the long spell of hot and dry weather experienced last autumn. It would be interesting to hear the experience of other growers as to these seasonable winter flowers.

F. W. BURBIDGE.

THE INVERNUS VARIETY OF CHRISTMAS ROSE (*HELLEBORUS NIGER*).
(Reproduced from a painting in oils by W. G. Moon.)

Miss F. J. Hope drove all the way from Edinburgh to Aberdeen in order to obtain the last named plant for her gardens at Wardie Lodge, where it increased and prospered, and long after her death I saw a long narrow or frieze-like bed of it in flower. Miss Hope during her lifetime was very proud of her Christmas Rose, to which allusions will be found in her classical posthumous work, entitled "Garden and Woodland," a work every true gardener should read who has not already done so. To return to St. Brigid's variety of the Christmas Rose, I first saw it in Mrs. Lawrenson's garden when she lived at Sutton House, on the breezy hill of Howth, near Dublin, but it is common here and there throughout Ireland, and stock has during recent years been obtained by nurserymen in England as well. Mrs. Lawrenson grew her Christmas Roses well both at Howth as also previously in Co. Kil

of flowers from October or November until February, or even later in some localities.

All the true Christmas Roses are seedling or selected forms of *H. niger*, which so far has resisted all attempts made to hybridise it with other species. On the other hand, the Lenten Roses are forms of *H. orientalis*, *H. colchicus*, *H. olympicus*, *H. guttatus*, *H. torquatus*, and other so-called species, which intercross or breed very freely with each other, the results being varieties innumerable. Again, the true Christmas Roses are not easy to grow to perfection on all soils, and are especially apt to fail on light sand or gravel or on limestone unless special provision is made for them. A deep rich loam, well cultivated, suits *H. niger*, and a situation that is shaded from mid day sunshine is an advantage. Like their first cousins, the Hepaticas, they like the proximity of rocks or stones, and like them are true

Chrysanthemums are grown for the supply of cut bloom, pot-culture has perforce to give way to a rougher and readier method that involves less labour. In the case I have in my mind cuttings are taken when available during the winter and planted in beds close up to the glass in brick pits. When they have rooted and made a little growth the points are pinched out to induce a bushy habit, and after being hardened off they are planted, about the end of April or commencement of May, direct from the pits into the open ground. Towards the middle or end of June varieties that mature at too early a date are cut down with the shears to a height of 6 inches from the ground, and in the first week of November the plants are lifted with good balls of soil and stacked close together on the floors of large Tomato houses. A good watering soon settles the soil about their roots, and a little heat in the pipes and ample ventilation for a day or so dries up any superfluous moisture that might induce mildew. Treated in this manner, the majority of the varieties develop

LATE CHRYSANTHEMUMS.

In his interesting note on the above topic "H. S." (page 521, vol. lvi.) speaks of *Niveum* being quite as late as *L. Canning*. I am not aware that this is a general experience. Certainly in the cases that have come under my notice during the past three years in South Devon, *Niveum* has been at its best from the middle to end of November, while *L. Canning* has lasted in absolute freshness until Christmas. The former, as perfect a flower for cutting as one could wish for, has not been available when most needed, and could it be prevailed upon to defer attaining the zenith of its beauty until Christmastide, I imagine that no other white would be required. *Princess Victoria* is also an excellent white, but this variety, though later than *Niveum*, has proved a trifle too early.

Where large numbers of Chry-

their flowers satisfactorily; indeed, as regards Niveum and some others, no difference is apparent between the blossoms on the lifted plants and those borne on plants that have throughout been subjected to pot culture. L. Canning, admittedly not too easy a variety to bloom satisfactorily, has fully answered expectations, this kind, however, not being subjected to the severe summer cutting back already alluded to. W. H. Lincoln, though doing well in pots, has proved useless for lifting, as it loses its leaves and produces scarcely any flowers. Luckily, its failure to accommodate itself to this treatment is a matter of small moment, as in Mrs. J. F. Fogg and E. J. Hill we have two fine late yellows that retain their vigour well and flower freely. The last-named variety is precisely similar to Tuxedo, mentioned by "H. S.," in habit, and its unexpanded buds show exactly the same bronzy-orange tint; when the petals reflex, however, their surfaces are bright gold, whereas in Tuxedo the petals are of similar colour on both sides.

Lady Lawrence does not take readily to the lifting process, but l'Enfant des deux Mondes produces quantities of delicate blooms under the same method which are useful towards the end of November and commencement of December. Possibly if cuttings of Niveum are struck as late as May, as recommended by "H. S.," the flowers might be available at Christmas, but cutting the plants down, even as late as July, has apparently no retarding effect. S. W. F.

THE STRAWBERRY TREE (BENTHAMIA FRAGIFERA) IN FRUIT.

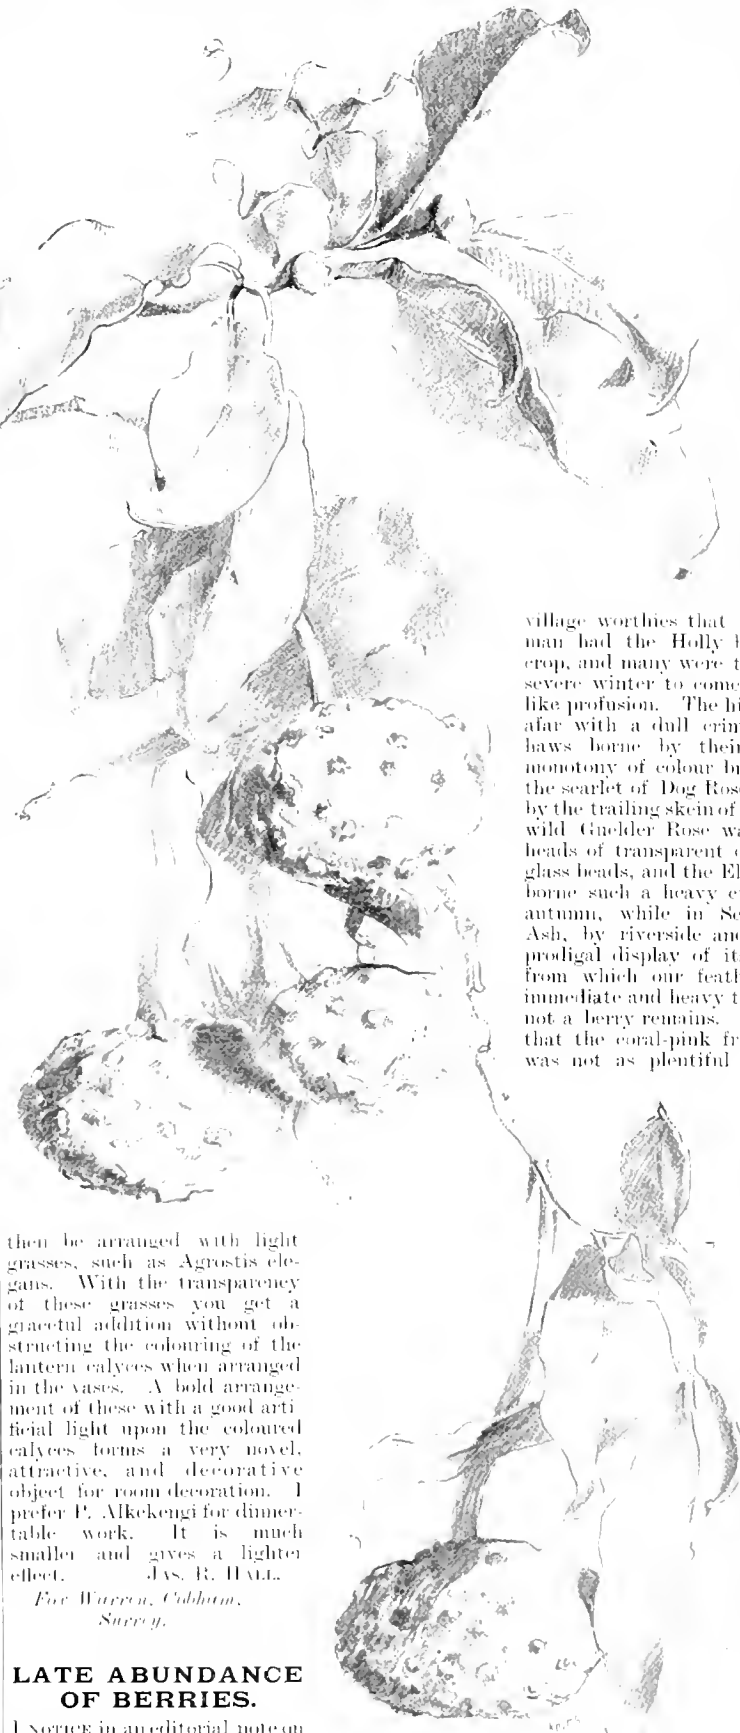

WITH this note I send some fruit of the above shrub. In consequence of the absence of much frost the birds have left the fruit on the bushes later than usual, and thus prolonged the ornamental character of the shrubs. Should we continue to get soft weather, the feathered tribe will doubtless get more palatable food, and leave the pendent branches laden with their large Strawberry-like fruit to lend a charm to the shrubberies for some months to come.

The Benthania is seldom seen except in the southern counties of England and Ireland, but there is no reason why it should not succeed further north, especially where there is a small annual rainfall and hot summers and autumns to harden the wood. When the wood is perfectly ripened it will stand 30° of frost, and where it would not succeed in the open, it is quite worth a place upon a hot south wall. Its large white sessile flowers are very ornamental in early summer, to be followed with abundance of fruit, as sent. It can be easily raised from seed, and as it belongs to the order Cornaceae, it thrives best in a moist situation planted in rich soil in a mild climate. When planted out as a single specimen on grass, it has a fine effect when in flower, as its lower branches sweep the ground. In such a position it spreads about equal to its height, but planted in a mixed shrubbery it will grow from 30 feet to 40 feet high. W. O.

Fota.

THE HARDY PHYSALISES.

THESE well repay good cultivation, more especially the variety Franchetti. For indoor decoration I very highly feed this kind, and support the stems with 2-foot stakes, and when the lower calyces are well coloured and the top ones still green the stems are cut 2 feet long, more or less, at the same time picking off all the leaves and tying the stems in bunches of about half-a-dozen in each bunch. They are then hung up in a dry room head downwards, which gives straight stiff stems. They can

then be arranged with light grasses, such as Agrostis elegans. With the transparency of these grasses you get a graceful addition without obstructing the colouring of the lantern calyces when arranged in the vases. A bold arrangement of these with a good artificial light upon the coloured calyces forms a very novel, attractive, and decorative object for room decoration. I prefer P. Alkekengi for dimmable work. It is much smaller and gives a lighter effect. J. S. R. HALL.

For Warren, Cobham, Surrey.

LATE ABUNDANCE OF BERRIES.

I NOTICE in an editorial note on p. 31 that in many districts of England Holly berries have been scarce. The opposite has certainly been the case throughout a great portion of the south and south west. During the

late autumn of the past year I journeyed by road from the easternmost limits of Southern Hampshire, through Dorsetshire to South Devon, and never have I seen such a wealth of berry on the Holly. In many places along the country roads great Holly bushes grew in abundance in the tall hedgerows, their shoots scarlet with tightly-packed berries. Here and there these lofty Hollies were garlanded with Traveller's Joy (Clematis Vitalba), the bright vermilion of the clustering berries, gleaming through the smoke-grey trails of the seed-laden Clematis, affording a charming colour contrast. In these three counties I

was assured by the village worthies that never in the memory of man had the Holly borne such an abundant crop, and many were the prognostications of a severe winter to come. Other berries were in like profusion. The high Thorn hedges glowed afar with a dull crimson from the countless haws borne by their loaded branches, the monotony of colour broken here and there by the scarlet of Dog Rose or Sweet Briar hedges or by the trailing skein of the berried Bryony. The wild Guelder Rose was brilliant with its flat heads of transparent crimson fruits, like large glass beads, and the Elders have probably never borne such a heavy crop as that of the past autumn, while in September the Mountain Ash, by riverside and copse, glowed with a prodigal display of its scarlet berry clusters, from which our feathered friends take such immediate and heavy toll, that at a month's end not a berry remains. In one district I noticed that the coral-pink fruit of the Spindle Tree was not as plentiful as usual, but this was

evidently due to some merely local cause, since in other localities it occurred in unwonted abundance. The Sea Buckthorn (Hippophae rhamnoides), with its grey-green foliage thickly set with clustering orange berries, has also presented a delightful picture.

S. W. F.

Chimonanthus fragrans from seed.

This wall shrub varies from seed, some forms being much poorer than others and less sweetly scented. Only the best forms should be preserved. A fine plant of the Winter Sweet against a sunny wall is an advantage, for the sake of the flower laden shoots to cut for room decoration.

FRUIT OF STRAWBERRY TREE (BENTHAMIA FRAGIFERA), SENT FROM FOTA, IRELAND. (This drawing, by H. G. Moon, shows a reduction of one-fifth from the natural size of the fruits.)

THE ROSE GARDEN.

ROSES AS STANDARDS.

DOUTBLESS readers of THE GARDEN can call to mind many fine specimens of Roses growing in various parts of the British Isles, but I am of opinion that more attention should be given to this subject, for the possibilities are great with many of our glorious Roses. I am thinking more especially of the vigorous growing Teas and Noisettes known as climbing varieties, and which embrace some of the loveliest colours imaginable.

How many of these fine Roses are seen in their true beauty when almost burnt up upon a hot wall. Much more pleasure would be derived from such Roses if they were grown as half or full standards, and as they developed their long growths trained out horizontally. I have seen many fine examples of such Roses as Niphetos, Belle Lyonnaise, W. A. Richardson, Réve d'Or, and others cultivated upon this plan.

There is one Rose in particular that everyone admires, but few can flower it successfully. I refer to Climbing Devonensis. I would advise those who have hitherto failed with this fragrant Rose to procure a half-standard of it, and plant very carefully in well-prepared soil. There should be a depth of 2½ feet to 3 feet of really good fertile soil, which, if not naturally, must be artificially drained.

The first year the tree is pruned back rather severely, and by the following autumn there will be a fine low growths. These must be protected with straw thatching or with mats during the winter if it is very severe, for it is a very tender variety, then the following spring no pruning is necessary beyond removing the extreme ends of the shoots and cutting any soft wood clean away. The long growths are secured in a horizontal position by placing some hop poles beneath the branches, arranged in such a manner as to form a kind of staging.

As the growths extend and increase in number annually this staging is also extended and widened as circumstances require, and in three or four years quantities of lovely fragrant blossoms may be obtained from the laterals which the long growths produce. These laterals are shortened back each spring to three or four or more eyes, according to their strength, and if too numerous the weakest are removed. When any of the old growths exhibit symptoms of exhaustion they are cut clean away in the autumn.

Naturally, the plant's requirements must be studied. A tree producing much growth will need extra nourishment, and after a time the soil must be replaced by some turfy loam. Manure from the cow-yard is recommended above any other, but two or three handfuls of bone-meal will be extremely helpful if applied each season.

This same principle of horizontal training could be adopted with what are known as dwarf plants, or, better still, with dwarf standards. A few of these introduced into the garden would not materially interfere with the cultivation of low-growing subjects that possess a very shallow rooting habit.

Roses such as Climbing Perle des Jardins, which grows so luxuriantly, the rich citron-yellow Duchesse d'Ancstadt, and the lovely E. Veyrat Hermans, reminding one of a bronzy-golden Charles Lefebvre, would be first-rate kinds to grow in this manner. So also would Maréchal Niel, the rich apricot-coloured Mme. Moreau, the nanken coloured Mme. Chauvry, one of the most delightful Teas in cultivation, the grand carmine-tinted Souvenir de Mme. Joseph Metral, the creamy-yellow Le Soleil, the pure gamboge-yellow Henriette de Beauveau, the last of the late Monsieur Lacharme's productions, and, indeed, a host of others too numerous to mention. In a good sheltered position and with careful attention in the matter of straw coverings, little apprehension need be entertained as to their capabilities of passing through an ordinary winter uninjured.

PHILOMEL.

AMATEUR ROSE CULTURE

PRUNING (concluded).

In one year (I think it was 1888) I had an extraordinarily fine growth on my trees—shoots from 12 inches to 18 inches long—and overnight I fancied a frost was coming; this was in May, and I told my man to be at my house quite by 4.30 a.m. Sure enough there was a terrible frost, and my lovely shoots, from which I was expecting so much, appeared to be perfectly ruined for the season. However, I said, we will either kill or cure; we will first of all syringe and afterwards with a small birch (made out of an old broom) we will knock the frost off as quickly as possible. The result was simply marvellous; I scarcely had a bad flower that year, and won over fifty prizes, many of them in very severe competitions. One box I remember in particular, consisting of six blooms of Annie Wood; they were perfect beauties, and Mr. d'Ombrain (who was one of the judges) said those six blooms were "absolutely perfect specimens." I owed my success to that early syringing; it saved my Roses for the year, and although it was only my third year of growing, it was a most successful one; notwithstanding, owing to that terrible May frost, 1888 was a very, very bad year for Roses in our neighbourhood.

When the shoots are well started I always mulch with short litter, being very careful not to bark the trees or damage the young shoots, and at the same time I give a small dressing of artificial manure, either pure dissolved bones or rape dust. Nitrate of soda I never use in spring or early summer, as it brings wood and foliage, and the blossoms are not so perfect either in colour or texture. Although I prune early, I do not find it brings me earlier blossoms than other growers obtain who prune later. I admit I am often very successful in the early shows, but I obtain these successes by carefully selecting the best early varieties. Now I must call your attention to that most dangerous pest—the maggot.

Maggots fat, maggots lean.
Maggots large, maggots green.
Maggots long, maggots short,
Catch 'em soon, or Roses nought.

The only cure for this pest is catching them. This can be done in the morning before the sun has any power, or at sunset. I go carefully over my plants every day, and with thumb and finger catch every one I can find, and by the end of May I will almost defy anyone to find a single maggot in all my 1250 trees. I make it a rule to pinch off every damaged leaf, so that if a maggot has been missed you may be sure to find it. Friends who visit me always remark on the cleanliness of my foliage. If specks of mildew should here and there make an appearance, I remove them also by pinching the leaf off and burning it. The aphid blight gives me very little trouble. The early coat of gypsum, lime, and soot which I give the earth I believe has much to do with this; but where it does appear, syringing with a solution of soft soap and quassia is the safest and best cure, and this should be used immediately the green fly makes its appearance. In this case truly "a stitch in time saves nine." One early washing is worth ten washings after the vermin has established itself thoroughly.

Next comes the thinning-out of the buds. Some varieties require to be done early; others, such as Annie Wood, the Verdier tribe, &c., are best left till comparatively late. It is quite a study to watch the growth and to do the thinning-out at the right time. I can lay down no hard-and-fast rule; but I can assure you that with a little experience in the matter, gained by your own experiments, you will find no difficulty in arriving at a decision as to when to disbud your different varieties.

Now, I will add a few words on the different varieties of Roses. Some, of course, do much better than others, and in this, situation and climate of course are big factors. That grand Rose, François Michelin, is a very good doer. I have now no less than three medals for this variety, and each time the bloom has been cut from trees planted close under a Thorn hedge which is sheltered from the morning sun. Trees of the same variety in another part of my rosery never do well. It is a grand

flower when you can get the colour right. Another Rose of which I am very fond and which I often show (although I seldom meet with it at shows) is Mrs. G. Dickson; it comes very full with me, but often has few petals; however, if cut at the right stage, it will stay as well as any Rose I know. Mme. G. Luizet is a grand variety, but apt to mildew, especially if over-fed with manure water (one year I lost nearly all my blooms of this variety through doing so). There are really such a vast number of lovely Roses grown now that one hardly knows which to choose. One thing we ought all to be proud of, and that is that Messrs. Dickson & Son should be the pioneers in introducing new varieties, driving foreign rivals clean out of the field. If only I had sufficient room, I would have two dozen trees of each of their best new sorts as soon as introduced.

Now as to

SHOWING.

I am ignorant of many points in the art of showing. I see men exhibit blooms at shows, and it fairly puzzles me how they manage to get the flowers just right for the judges. At times my flowers come lovely, at others they seem to stand still and do not expand as they ought to. However, I must not grumble. Last year with my little lot of trees I won sixty prizes and two cups, including the Reigate challenge cup (open to all England for growers of less than 2000 trees), and three medals, and if I do no worse this year I shall be quite content. During the thirteen years that I have grown Roses I have taken over 500 prizes and a goodly number of medals. I select my best blooms and protect them from wet previous to cutting for exhibition. This is quite a necessity when one is so limited for space and trees as I am, especially as I show against competitors who have as many as 12,000 trees. The system of limiting exhibitors in certain shows to exhibit only against men of their own weight in regard to number of trees has given great satisfaction, and I for one hope that the plan will be extensively adopted, as otherwise small growers are unfairly handicapped and become quite discouraged. I advocate separate classes at all shows, which will prevent a grower with only 200 or 300 trees having to show against a competitor with 2000 or 3000 trees; and also which will prevent the man who has perhaps from 10,000 to 20,000 trees competing with the smaller man who has 2000 or 3000 plants. I myself have been swamped in a north of England show by an exhibitor who has many thousands of trees to cut from, and who did not disdain to compete in the small classes of six and twelve varieties, as well as in the classes for twenty-four and thirty-six varieties. The man with a medium-sized rosery is entirely swamped in such cases, to say nothing of those enterprising Rose lovers who have only a few trees, and who, I hold, should be given every encouragement in the work of beauty which they have undertaken.

Leaving showing and reverting for a moment to cultivation, I may add that as soon as I have finished exhibiting I always go carefully over my trees and thin out the spindly-looking new wood. I then wait till the first week in September, when I cut the whole of the old wood and leave only the new growth to supply the cut-backs for the next year. You will thus see that however old my roots may be, my Roses are produced each succeeding year on absolutely new, or maiden wood. By cutting away all the old wood in September, one, of course, sacrifices some autumn blossoms, but by doing this the new wood ripens off so much better, and the strength which would have gone into the old wood, in order to produce a few autumn blossoms, is conserved and the plants will return the capital, with good interest, in the following summer.

In conclusion, I ask of you to remember that every flower that is produced adds to the beauty of this earth on which we live, and I believe that even the most callous and unimaginative beings we meet cannot remain long in the presence of these most beautiful flowers without being awakened to some sense of the beauties of Nature, and without turning their thoughts to the Creator of all, who sends these beautiful things to make our life here bright and happy.—R. E. West, in "Rosarian's Year-Book" for 1900.

THE FLOWER GARDEN.

CYCLAMENS AND HEPATICAS.

I THINK that two good old-fashioned flowers are not generally grown enough in gardens—hardy Cyclamens and Hepaticas. At Oakwood we have a long side of a mound facing south with a ditch in front, having nut trees on the other side giving shade. At one end of the mound are established plants of different forms of hardy Cyclamens with a sunk piece of stone to each plant; next to these, Hepaticas, and then seedling Cyclamens. Last year drought did not agree with the Hepaticas, so we moved them to the north-east side of the mound, planting them in nests of sunk stone, with small pieces of stone laid on the surface between the plants. Stone, if it has been exposed to weather and has mossed, is no disfigurement, and the plants seem happy in their new quarters. Many years ago we planted a single pink Hepatica on a rather dry bank where it got some sun; this had good sized pieces of sunk stone all round it which seem to have given sufficient moisture, as the plant has every year flowered beautifully and held its leaves. My friend Mr. Frank Miles told me that Van Swaelman, a Dutch grower, had Hepaticas of many shades of colour. I got a set. They have good flowers, but the plants did not increase as fast as I could wish. I have great hopes that in their new place they will grow stronger. We shall fill up the space on the mound from which they were taken with Cyclamens. The beauty and variety of their leaves make the mound pretty even when flowers are not out, and the effect is much better with a good large bed.

GEORGE F. WILSON.

AURICULAS IN WINTER.

THE Auricula plant is one of the earliest to wake up into life and beauty; but as I write these lines (about the middle of January with 7° of frost in the air) there is no sign of any movement in leaf or bud. I write a few lines about the Auricula at this time because I have heard from two famous growers in the north, who both report, "Auriculas look well, and make a good show of green foliage for the season of the year." It is rather singular that my own plants are the reverse of this, having lost their foliage to a greater extent than usual owing to the severe frost, which tried them greatly. It was keen for several nights, and fell once 25 below zero. Auriculas can stand a low temperature fairly well, but such a low temperature as 7° Fahr. destroys many leaves. After the frost is gone it is

necessary to go over the entire collection and remove all the dead leaves. They must be taken clean out at the base, for if parts of the decayed leaves are left they may destroy the plants by causing the main stem to decay, and when decay has fairly set in on the main stem of an Auricula the chances are that the plant itself will be destroyed. I am alluding to the show Auricula, which comprises the green-edged, grey-edged, white-edged, and selfs. These are quite distinct from the alpine Auricula, although all Auriculas may be called alpine, as they are all found in mountainous districts in the south of Europe, especially in the Alps. The show Auriculas are not quite so easily grown as the alpine section, and seem to suffer most in damp and wet weather.

Probably the first parent of the show Auricula is less hardy than that of the alpine type. At the

pots. The plants are very small, and a dozen of them may be put into a 3-inch pot. The most curious phenomenon about Auricula seed is its irregularity of germination, and if the seed-pans are kept for three years, seedlings will still be produced, the latest to flower being usually the best varieties. Seed is also very difficult to procure. The best flowers have to be sacrificed by cross-fertilising them when in their best condition, and only about one pod in six will contain seed; but of course if it was easy to obtain good seed, and as easy to raise good Auriculas, good flowers would not be so scarce as they are. The progress is still very slow, and it would be well if some amateur with leisure would begin the raising of new Auriculas, for we ought not to let these lovely flowers remain as they are, as we are still far from perfection. The two Ne plus Ultras of Smith and

A COLONY OF HARDY CYCLAMENS IN THE WISLEY GARDEN.

Auricula and Primula conference in 1885 it was decided, as far as the matter could be decided, that the first parent of the show Auricula was the Primula Auricula of the Austrian and Styrian Alps, and that the alpine Auricula was from Primula pubescens. These two species are well known, and it is also known that both were cultivated in gardens upwards of 300 years ago. At the time when Clusius published his "Rariorum Plantarum Historia," in 1601, both of them were in cultivation. Clusius himself introduced P. pubescens, but P. Auricula in the time of Clusius was widely grown in Belgian gardens. The latter Clusius figures as Auricula ursi, and his own introduction as A. ursi 2. How the show section has been brought to its high degree of excellence it is difficult to say, probably by crossing with some other species, or, what is not improbable, by selection from seminal varieties. The selection of distinct varieties from seed is an interesting process, and no lover of the Auricula can resist the temptation to raise seedlings; but to a beginner in Auricula cultivation much patience is needed, for the seed, though well and fairly sown, does not all germinate in two or three weeks. In less than a month tiny plants will show themselves, and when these have made one good leaf after the seed leaves it may be best to re-plant them into small flower-

Fletcher have long been surpassed, and the latter's flower has been discarded from every good collection. There is plenty of room in all the classes for other Ne plus Ultras, but it requires much patient waiting for the development of flowers possessing the highest points of excellence. Nevertheless, there is much pleasure in waiting and watching the development of the plants, for if there is anything in Nature more beautiful than an Auricula flower it is an Auricula leaf. A fancier who loves and values his Auriculas can distinguish one plant from another as well by the leaves as by the flowers. Some of it is green of various tints, while the green-edged varieties always have green foliage; the white-edged, grey-edged, and self classes contain others with foliage pure white and some cream colour, owing to its being densely coated with farina. In April the trusses of flowers develop, and the plants ought to be placed in a glasshouse, so that they can be attended to when the weather is wet or in any way unpleasant outside.

Having written so much, it may be well to finish with a few remarks on culture.

SEEDLINGS.

The seed is sown as soon as it is gathered in July, and some of the seed will germinate in three weeks, more of it in February and March, and, as previously stated, many belated seedlings will appear in the course of the next three years. They must all be attended to as they appear, and be grown into nice flowering plants. A seedling will take twelve months to grow into a flowering size; but it is exceedingly interesting to watch this development of leaf and plant into full fruition, and it is probable that the first truss produced on the seedling plant will be better than any future one, as they do not always maintain their maiden promise of goodness. Named varieties and choice seedlings are propagated by offsets, and in no other way; consequently when a new variety is shy in

producing offsets it takes long to get up a stock of plants. A good plan to hasten the production of offsets is to cut off the head of the plant when it has a main stem long enough above the surface of the soil in the pot. Before doing this the root part must be in quite a dry condition, as not only will the top part strike out roots more freely, but the plant itself will not be so likely to rot.

Early in February the entire collection of flowering plants should be surface-dressed. To do this effectually a portion of the top soil must be removed, and in doing so examine the neck of the plant, for around it may be clustering the troublesome *Auricula aphid* (*Triana auricula*). This must be carefully removed with a small brush. I keep a pepper-box beside me and dip the brush into the tobacco powder contained in this receptacle, dusting it well into the aphides and brushing them out. The surface-dressing consists of good fibrous loam and decayed manure in equal portions. Press it in firmly; see also that there are no aphides (green-fly) on the leaves. The plants having been kept in a dry position up to the time of surface dressing, it is well to give them a good watering, and if the plants have been placed in an Auricula house, they should not suffer from frost under favourable conditions. The plants must be placed near the roof glass and freely aired. Attention must also be given to keeping the plants in a satisfactory condition at the roots. Do not give too much water, however, but rather be careful not to err on the side of over-dryness; also be careful not to apply any water to the leaves. The time for blooming is from the second week in April to the end of that month, but some early bloom may even open in March, and a few specimens may run into May, but there is a saying in the north that "The Auricula in May has had its day."

When the blooming period is over the plants should be again removed to garden frames on the north side of a wall. This is the right position for them during the summer months. At this time also the plants should be repotted and rearranged in their order in the frames, always beginning with the green-edged varieties, following on with the grey edged, the white-edged, and, lastly, the selfs. Some care is necessary in repotting. The flower-pots used should be clean and well drained, some fibre shaken out of the loam heap being placed over the drainage. The compost should consist of four parts good fibrous loam, one part leaf-mould, one part decayed stable manure, and, if necessary, some coarse sand. The plant itself after being turned out of its flower-pot must be carefully examined. The base of the main stem, called the "carrot," is sometimes in a rotten condition. All decayed parts must be removed, and, of course, all the *Auricula aphid* on the roots must be cleared off. Work the soil well in amongst the roots and pot firmly. After repotting, watering must be done very carefully until the plants have well established themselves.

A very good time for getting off the offsets is in February, when the plants are being surface-dressed. They must be carefully removed from the parent plants, using a sharp knife, or in some instances they may be removed by hand. When Auriculas are in flower they must be shaded from the sun, as the blossoms shrivel if exposed to sunshine for a few hours. J. DOUGLAS.

GARDENING OF THE WEEK.

HARDY FRUIT GARDEN.

THERE is much work that must be got through in this department between the falling of the leaves and the bursting of buds in spring, such as pruning, tying, nailing, and cleaning the trees, and also manuring and digging the ground. The work done should be regulated according to the weather, the lighter work, such as nailing, being done when it is mild, and that which requires more exertion when it is cold. When the weather is too rough to allow of working out of doors,

shreds may be cut, stakes sharpened, and fruit looked over undercover.

FILBERTS AND COB NUTS.

The Kentish system of growing these is the best. A main stem branches a short way from the ground, the branches forming a flat top with the centre open. Remove the suckers, prune off from the branches all shoots having a tendency to grow erect, and do not allow the branches to become crowded.

APRICOTS.

The pruning of these is similar to that of Plums and Cherries. The work of nailing (tying if the walls are wired) may be done at the same time.

ENEMIES.

Protect the buds of Plum trees with nets of small mesh against the ravages of bullfinches; or the buds may be made distasteful to these wholesale destroyers by syringing with water and paraffin oil at the rate of a gallon of the former to a wine-glassful of the latter. The mixture must be kept in motion by one man syringing into a pail, while another puts it on to the trees with an insecticide syringe. Another method is to syringe with water, and while the trees are wet to dust over with newly-slaked lime and soot. Their numbers may be reduced with a gun, taking care not to injure fruit and other valuable trees. These birds have also attacked Cherries.

The trunk and main branches of trees with moss and lichen growing on them may be painted with limewash containing an admixture of soot.

For American blight, wash the affected parts with paraffin oil and water of the same strength as recommended above for buds, or use soft soap water at the rate of 8 ozs. of soap to a gallon of water, rubbing it in well with a brush. Protect Gooseberry bushes from bullfinches in the same way as Plums. Another mode of protection is to pass black thread round and round the bushes.

After the pruning and tying is done, dig the ground between fruit trees, being careful not to damage the roots.

RASPBERRIES.

Shorten, stake, and tie Raspberry canes and manure and dig between them. G. NORMAN.
The Gardens, Hatfield House, Herts.

KITCHEN GARDEN.

POTYROES.

The seed should now be started for either frame or pot culture. Often a few pots may be sowed, and these stood in early fruit houses will give tubers at Easter. Some cultivators pot up the sets in small pots, but my method is to place them in light compost in shallow boxes. They will be ready in three weeks to pot or plant out if given a warm place to sprout in.

SPINACH.

Few vegetables are more uncertain in old garden soils than Spinach. If there are any bad plants, now is a good time to make up losses. I am aware this vegetable is not often grown under glass, but it well repays frame or pot culture. A few lights of a frame sown with Spinach early in February will give a good cutting in April, but all cannot give frame culture, and if seeds are sown in small pots in a frame and planted out early in April on a warm border, there will be a good return.

EARLY CABBAGE.

This vegetable is more appreciated in April and May than later, and the most should be made of the early crop. To assist growth I draw the soil well up to the lower leaves to prevent frost damaging the stems. I find we obtain better results by feeding when growth commences early in the year with a good fertiliser, than by placing large quantities of manure in the soil when planting.

CUCUMBERS.

Early in the spring there is a demand for Cucumbers, and there should be no delay in sowing the seed and preparing the beds for the plants. With hot-water pipes as the heating agency there is little trouble, but with manure more attention is needed. If the latter is used, it is well to sow and make the beds up at the same time, as by the time the plants are large enough—that is as soon as the third leaf appears—the bed will be in proper

condition. Avoid rank manure from any source, as this means trouble; the manure should be prepared in the open and sweetened by turning occasionally. By close attention to details such as heat and moisture, fruits may be had in six weeks or two months from the time of sowing. Seeds are best sown in small pots, using bottom-heat and only just enough moisture to effect germination. When the seedlings are planted out, only a small quantity of soil is needed at the outset, and this should be light and rich, as it is best increased later on by frequent top-dressings. Cucumbers rejoice in a warm temperature—about 70° or more in the daytime, and 5° to 10° lower at night in cold weather, with very little ventilation indeed. Avoid over-cropping to begin with, as the plants bear so freely if allowed that they are much weakened. In planting, place near the glass, but free of cold winds. In winter I cover the glass at night. GEO. WYTHES.

Syon Gardens, Brentford.

INDOOR PLANTS.

CLIMBERS.

CONSERVATORY and greenhouse climbers of many kinds, including Passion Flowers, *Taesonias*, *Clematis indivisa*, *Tecoma jasminoides*, *Jasminum azoricum*, *Lapagerias*, *Plumbagos*, and *Heliotropes*, should now undergo their annual pruning, as it is well to get this work out of hand early to give time to deal with pressing work, which will soon come in plenty. With most of the above, pruning resolves itself into simply cutting away all the weak growths and some of the strong, leaving only skeletons of the plants, which will soon break again into vigorous growth and cover all the space allotted to them. Vigorous plants of the *Lapageria* may have many of the smaller spray pieces cut out entirely and a judicious thinning all over, shortening some of the strongest leads that have got out of bounds, but it is not wise to cut away too much or to make the plant over-thin, as it will bear more crowding than the others mentioned, and even weak growths on established plants flower freely. Plants which have not yet become vigorous should not be pruned at all, for the more growth they have the more freely will they root, and it is impossible to get the vigorous shoots one wants from badly-rooted plants. *Tecoma jasminoides* should have some young wood left in, and I have found it best with this plant to cut out now and then an old growth boldly to make room for vigorous back breaks. With the *Jasmine*, too, it is well to lay in some young wood at the expense of sacrificing older pieces.

HELIOTROPES AND PLUMBAGOS

may be spurred close in to the main shoots, and *Fuchsias* (climbing) may be served in the same way. *Taesonias* often get infested with white scale, and as the wood is too tender for the use of insecticides of sufficient strength to kill the insects, all efforts to thoroughly clean the plants are unavailing, though much may be done to reduce the pests by a vigorous application of soft soap and water to the old wood. As *Taesonias* come true from seed and are vigorous in growth, I like to have a few young plants always at hand for planting when the scale gets too bad on the older plants rather than leave the latter to become a source of danger to their neighbours.

For many positions unsuited, through shading, for flowering plants I find the various climbing or running forms of *Asparagus* suitable. *A. Sprengeri* is the quickest grower, and, grown in large suspended baskets from which the growths may be trained to cover with a graceful light greenery much roof space, they answer all the purposes of climbing plants and are clean. *A. deflexus* is also beautiful, but looks best when the growths droop vertically from the basket to or near the floor. For planting out and climbing upwards *A. plumosus* is the best. To keep up stock young plants of the two former may now be transferred to baskets, using good loam and sand as the staple soil. Such baskets, if big enough (I use them 16 inches in diameter), will keep the plants in good condition for two or three seasons. J. C. TALLACK.

Livermore Park, Bury St. Edmunds.

CHRYSANTHEMUMS.

PROPAGATING.

THE old method of striking the cuttings in cold frames is now almost obsolete, and should only be resorted to when necessary, for the reason that the cuttings remain far too long inactive. During severe weather in the depth of winter the young plants must often be securely covered to exclude frost, which means that no light, air, or attention can be afforded them; on the other hand, a strong forcing heat should always be avoided, or a weak, sickly growth will result. The most satisfactory mode of treatment that I am acquainted with is to place a small frame or hand-light on a stage as near the glass as possible in the greenhouse, or some other structure kept at a greenhouse temperature. This should be filled with finely-sifted cinder ashes, leaving sufficient depth only for the reception of the cuttings, or, better still, plunge the pots close to the glass in cocoa-nut fibre. The cuttings can then be attended to at any time and in any weather. The lights should be ventilated more or less at all times, keeping them sufficiently close to prevent the cuttings from flagging. Very little water will be needed until they are rooted. Syringe gently once a day in early morning for the first week or two to keep them in a tresh condition.

The above remarks apply to Japanese, incurved, reflexed, and large-flowered Anemones, whether intended for large flowers or specimen plants.

BEST VARIETIES.

Those on the look-out for new and promising varieties, and have not had the opportunity of seeing them cultivated, may be recommended to grow the following:

Japanese. Miss Alice Byron, pure white; Pink Minc, Carnot, very promising; Lord Salisbury, bronzy yellow; Mme. von Andie, a very pleasing sport from Mutual Friend, sulphur yellow; Mr. H. E. Fry, good light yellow; Mrs. A. Tate, sport from the well-known Etoile de Lyon, a most desirable and pleasing shade of red, quite distinct; Mme. R. Cadbury, a magnificent white, but a little late for November shows; Mrs. W. Morgan, yellow and cream; Souvenir de Marquise de Salisbury, a pale yellow sport from the popular Chenon de Leché, should prove of much value; Mrs. W. Cussham, white flushed with blue, a fine exhibition flower; Florence Molyneux, pure white, an immense flower, and one of the finest seen during the past season; Edith Pilkington, splendid yellow, much in the way of Boule d'Or, should become a general favourite; Vicar of Leatherhead, a seedling from Mme. Carnot, golden yellow, large and fine; Silver Queen, mauve-pink, good; Sir R. Buller, very fine crimson, said to be a seedling from E. Molyneux; Mrs. Ewart Barber, another fine white; Mrs. G. Barnes, primrose, tipped pink, very refined; W. H. Whitehouse, a promising flower, colour rosy red; Nellie Perkins, sulphur-shaded pink; Edith Perkins, a fine incurved Japanese pink.

Incurved. Ralph Hatton, purple, fine form; General Symons, bronze, good; Matthew Russell, bronzy red, excellent form; Mr. F. King, silvery

pink; Mrs. W. Howe, amber, very pretty; and Annie C. Love, striped pink. EDWIN BETKETT.
Aldenham House Gardens, Elstree, Herts.

A BORDER AT SEVERN END.

THE border, of which an illustration is given, in the beautiful gardens at Severn End, Worcestershire,

PEAR BEURRE BOSC.

RECENT notices of this handsome Pear remind me that I have never seen it so good, or so much grown elsewhere, as it is in East Anglia. Many gardens in Suffolk contain trees of it, and I do not remember seeing any undersized or poor fruit in the Bury St. Edmunds district, though the soil in that neighbourhood, speaking generally, is not a good

A BORDER IN THE GARDENS OF SEVERN END, WORCESTERSHIRE.

is interesting for the succession of flowers and high Box edging. I think it is unfortunate that this form of edging is disappearing. There is a fresh bushy look about healthy Box that appeals to me, and it should not always be kept severely clipped. Amongst evergreen permanent edgings I count the Box one of the most important. E.

one for Pears. Beurre Bosc when well grown and ripened on a wall is of very good, if not very distinct, flavour, and the fruits would no doubt be appreciated by most people. The tree is a first-rate grower, strong, and at the same time forms fruit spurs freely and bears well. It is a good garden Pear. J. C. T.

KITCHEN GARDEN.

MUSHROOM GROWING.

MUSHROOM growing has always been the conundrum of horticulture. Everyone who has a garden or a greenhouse has at one time or another tried to solve the question how to grow Mushrooms. Success has attended the efforts of the few, but many have been disappointed. To see a good bed of Mushrooms is a sight to be remembered, and they appear to be easy to grow, and yet the majority of those who attempt their cultivation fail to succeed. And yet what is more sought after in the market and shops? The wild Mushroom confirms the idea of the simplicity and the mystery of its growth. What other product of the garden asserts itself with such freedom and wilfulness? There is never a glut of them so as to stop their sale, as the public will give 1s. per lb. for wild Mushrooms as readily as they will

day three or four times, when it will be ready for making up into beds. A good open shed is the best place to prepare the manure, so as to dry it thoroughly and allow the steam to escape. If the building in which the Mushrooms are to be grown is about 8 feet high, it will be easier to make the bed. This should be trodden as firmly as possible, and when finished should be about 18 inches deep. It should be left in this state for one week. If the spawn is in bricks it should be new, and purchased from a reliable firm, or if gathered from an old hotbed or Mushroom bed it should look fresh, and not stringy. Break the spawn into pieces about 2 inches square, and place each portion in a hole made with any suitable iron tool about 2 inches below the surface of the bed and 1 foot apart. When the bed is spawned, firmly tread it again and cover it with 2 inches of soil. This should be trodden down and finally beaten level with a spade or shovel. Cover over with a foot of clean straw—long manure may be used, but as this harbours insects, the straw is best—and close the place. The heat of the bed will cause the spawn to run. The time for making may be March, or

sourness and poverty. But when brought to the surface, a heavy dressing of short manure, decayed garden rubbish, and soot, spread over the surface and forked in, soon creates fertility, and exposure to the air rapidly removes moisture and sourness. A. D.

As one who studies vegetable culture I have read the note on the above with considerable interest, and, much as I admire Mr. Beckett's splendid exhibits of vegetables, I am sorry to differ from him in his treatment of clayey land. Having failed myself in my early days, I would ask readers of THE GARDEN to mark, read, and inwardly digest before going to the extremes advised. In every garden circumstances differ. In the first place, with a deficiency of labour I would hesitate to bring up poor, inert soil 3 feet in depth and bury the top soil. The writer adds he worked in plenty of manure and other aids, and this procedure is not always practicable, as in many gardens the difficulty is to get sufficient manure. Indeed, I envy Mr. Beckett: his lines have fallen in pleasant places in obtaining sufficient labour and the materials to make the soil so good. My experience is so different; and once I buried a good soil, following Mr. Beckett's advice, with the result that our crops were a failure for years, and though I am at one with him as to the value of trenching, so much depends on the soil trenched. Some soils at 3 feet are so poor, that years of labour and unlimited supplies of food will not make them good. In my own case we have say 12 inches to 15 inches of soil on a sandy gravel subsoil. Now what use would this latter be on the surface, as so far I have found it will not do for vegetables? AN OLD HAND.

AN OPEN-AIR BED OF MUSHROOMS.

for the cultivated ones, and occasionally they may be brought for one penny per lb. The accompanying photograph of a Mushroom bed proves that the grower understands them, though this was not his first attempt at their culture. A successful grower, not only of Mushrooms, but of any flower, fruit, or vegetable, meets many a reverse before he is finally successful, and this is one reason why he refrains from giving publicity to his experience. A wooden building without any means of artificial heating was the place in which these Mushrooms grew, and the month of May the time they were gathered. They were not grown to photograph, but to sell, and every saleable Mushroom had been gathered three days before the photograph was taken. They were all sold for 10d. and 1s. per lb., and the bed was in full bearing for weeks. Several tons of horse droppings were used in the making of the beds.

The droppings which have been shaken out of stable manure should be taken and left in heaps under cover, lying as lightly as possible, not more than 3 feet deep for a day or two, then turned over and shaken loose, letting it remain on the floor about 2 feet deep. Repeat this process every other

any of the following five or six months, for cold buildings, or any time for heated buildings; clear off all the straw five or six weeks after spawning, care being taken not to knock off any of the young Mushrooms.

Accomb, York.

GEO. HOLMES.

DEEP CULTIVATION OF SOIL.

WHATEVER may be the nature of Mr. E. Beckett's reply to Mr. Hall's query as to the Aldenham method of trenching soil, he cannot very well, without showing undue egotism, say, what others can so much better say, that if ever results have justified methods, they have been furnished in the kitchen gardens at Aldenham. Mr. Beckett is a famous grower of the most beautiful of vegetables, literally everything thriving luxuriantly under his treatment. Those results speak volumes for the success of his deep culture. No doubt many persons have had cause to look with fear on such very drastic operations as bringing from low down any form of subsoil, whether clay, sand, or otherwise, because of its

Mr. EDWIN BECKETT has opened up a large and interesting subject upon which there are many diverse opinions. I may say at once I most thoroughly agree with what he has advanced on deep cultivation, and those of a contrary opinion may well study what Mr. Beckett has so clearly set forth. In the deep digging question I got my lessons many years ago when working side by side with my late father. Any attempt at shirking the bottom was soon known by my father exclaiming, "Now then, young man, fetch that bottom up," and similar remarks to the same end. In the course of the work I got various hints about the bit of "yellow stuff" down below. "There is money in that; it only wants bringing to the surface." These and similar remarks to the same end, coupled with the fact that I was working beside a thorough spadesman, made me an excellent master of that tool long before I was sixteen. There are those to-day who dread seeing a bit of yellow soil on the surface—soil they have been brought up to nickname "inert" for want of a truer description. Those that talk so much about inert soil at a few inches deep have given no thought to the subject. Trace the deep roots of any big Oak or Beech, and where do we find them but in this very material. But the giant trunks of these trees do not endorse the idea of "inert" soil; far from it. It is the same in the garden. In trenching a new piece I was always taught to put the best soil where one expected to find the great mass of roots later on, and bring the bottom soil up for treatment by aeration, &c. Only a few weeks ago I saw a piece of ground being muddled over in the way I deplore, while the "dressing" of manure may have come through a pepper castor, so nicely as it arranged. The greatest depth moved by the spade and the man would not average 5 inches if honestly measured. I would like to ask those who talk about inert soil at what depth they consider this to occur. I will give two instances. The one was of soil taken from a deep cutting of the Banbury and Cheltenham direct railway, at a depth of 20 feet to 30 feet; the other was of soil taken from the Penge tunnel frequently at 100 feet or 150 feet in the earth. In the first the soil was blue lias clay, solid, heavy and retentive to the last degree. Of this material hundreds of loads were carted on to a piece of sharp sand that previously would not grow wheat straw a foot high, and no other crop was of the slightest use. On this land cartload after cartload was

shot down side by side, and eventually rough levelled, and left for the frost to pull to pieces, for it was in great clods many pounds in weight. In this case the clay was carted on for a definite and good purpose, and the crops taken without the aid of manure were simply astounding. In the Ponge tunnel case the soil was the output of one of the shafts, and it so happened that the kitchen garden was largely made up of the most greasy and treacherous rolling clay of which I have had experience. When I took charge of the garden a pail of water was an absolute necessity in digging at any time. All flower beds had to be specially made, which was no light work, seeing there were hardy bulb and flower beds by the dozen. Before taking charge the kitchen garden had been a hopeless failure, and to this I gave much time and trouble. Deep digging, the addition of leaf-soil, of which luckily a great quantity existed, light manure, and abundance of grit gradually brought this into a most prolific garden, and finer Leeks, Cauliflowers, and Celery I have yet to see. Special strong forks were the chief tools, spades and all akin being, I found, out of the question and unreasonably laborious. Rough winter ridging I greatly favoured, and by growing Leeks Celery fashion, the ground was deeply moved in summer also. A near neighbour solved his difficulty by firing, burning a set piece each year. In this case also splendid crops resulted. And yet there are those who talk about inert soil at less than 18 inches deep. My own belief is that common-sense and proper working will render any class of soil productive, and, regardless of its quality, nothing short of rock or stone should prevent every atom of soil being rendered available for the crop on the land.

E. H. JENKINS.

Hampton Hill.

Mr. E. BECKETT, like many other good men who have preceded him, has advanced new ideas relative to the advantage of a thorough and exceptionally deep system of trenching, and his advice, I notice, has already been questioned by a correspondent in THE GARDEN, January 29 last. This may be but the forerunner of many others, the writers of whom may or may not have attempted to follow the advice given. What I have seen in the gardens at Aldenham House within the past twelve months goes to prove that Mr. Beckett practises what he preaches. Just one instance will perhaps suffice. A new piece of meadow land had been taken in and the ground deeply trenched, if my memory serves me rightly, between 3 feet and 4 feet, and treated exactly according to the information given on page 32. A heavy crop of Potatoes was first gathered, and this was followed by an exceptionally fine lot of Savoys later in the year. This method of deep cultivation is consistently carried out in all parts of the kitchen garden, and if proof were wanted of the success of Mr. Beckett's system of treating the soil, his excellent exhibits at the meetings of the Royal Horticultural Society in recent years should be ample for this purpose. The crops as a rule are of a high order of merit in all departments.

D. B. CRANE.

WHEN a strong man with deep convictions has an object in view he goes straight for it. This is what I admire in Mr. Edwin Beckett's remarks upon deep cultivation on page 32. But if we bring up the crude, bad subsoil to the top, we must also add improving substances in a very liberal manner. This Mr. Beckett has combined with his deep trenching, hence his success; and the absence of this ameliorating treatment will in most cases account for failure when failure has followed a reversal of the top and bottom spits.

Many years ago, when I was a youngster, I served for seven or eight years under one of the best fruit and vegetable growers I have ever known. He was a hard-headed York-shireman, and always went straight for his object; but, like the careful, skilful man he was, he made provision for improving the bad stuff brought to the top as he went along. In those days a good deal of forcing was done on the old hotbed system, chiefly with oak and other leaves. Hundreds of loads were raked up every

winter and carted to the kitchen garden for the purpose. In addition, all the rubbish of the garden and waste soil from the potting shed was available. Some of the rubbish was smother-burned, with lumps of clay piled over the fire when well started. With such means at disposal and plenty of labour, six or seven acres of heavy land were soon brought into a splendid condition for cropping, and even a timid man similarly placed would not hesitate to adopt the same method of improvement. I have known cases where trenching in the way described has, for the time being, done harm, but that was because the bad soil was brought to the top and nothing done to improve it. I have heard men argue that if the same liberal treatment had been adopted with the surface soil, the labour of trenching might have been saved. But the surface-scratching men were in a bad way last summer, as they always are in a dry time. A mule of manure is, of course, valuable in a dry time, but especially so when the hard pan has been broken up below to let up the moisture stored away there. The top soil was once in the condition the bottom soil is in now, but exposure to the atmosphere and the annual decay of vegetable life have improved it, and the same course should be taken with the bottom soil. Of course the intelligence of the cultivator will suggest that it should be done in a more rapid manner. No vegetable grower should be satisfied with less than 3 feet of good workable soil—that ought to be the aim, though in many cases, from the lack of means of improvement, the whole object has to be deferred. There is one means of improving cold clay land which everybody might adopt with advantage, and that is burn some of the clay, and top dress with it to the depth of several inches to open up and warm the staple.

E. HOWARD.

FRUIT GARDEN.

APPLES AND PEARS.

PRUNING takes a long time and requires to be done with judgment, according to kinds and varieties of fruit. With the majority of varieties of Apples I adopt a free-growth system by leaving young growth its full length, on which flower buds form when two years old. To avoid crowding I prune awkwardly-placed branches back to a wood bud, so that warmth from the sun and air have free access amongst those remaining. I resorted to this system with pyramid, bush, and standard Apple trees, as practice and observation had taught me that the close-pruning system I formerly followed brought on canker with free-growing trees. Weak-growing varieties which do not require much pruning should be selected to form espalier-trained trees; such are Manks Codlin, Manning-ton's Pearmain, Wealthy, and Dutch Mignonne.

Pears are amenable to close pruning. Under this system they continue for many years in good health and bear regularly. They are therefore adapted for training into different shapes. The best are those trained horizontally or as cordons and pyramids. The pyramid is by far the best for open ground. I prune my trees to form pyramids of cordoned branches—that is, they have a main stem in the centre with branches starting from it. Many trees have as many as fifty branches, some of which are 12 feet long, so that I have as it were fifty single cordon trees in one. Most of the pruning is done in August by shortening the summer side growth to within an inch of the base. Now is the time to shorten second growth and shorten and thin out spurs. It is a too common error for spurs to be overcrowded; they require room to allow the leaves to attain their fullest size, when large, well-ripened bloom buds will follow. It is better to err on the side of thinness rather than for the spurs to be crowded.

Stake and restie trees that are not sufficiently established to hold themselves firm without this aid. In the case of horizontally-trained trees one pair

of branches is as much as can be obtained in one season. To induce the leading shoot to break to obtain them, shorten it so as to leave three eyes, two to be opposite as near as possible; these will form the first pair of branches, and one above them will make a leader the following season.

PLUMS, DAMSONS, AND CHERRIES.

Thin out the wood of Plums, Damsons, and Cherries growing on open ground, and shorten any shoot growing beyond the outlines of the trees to keep them in good shape. The two former are liable to throw up suckers, and if any exist, they should be traced with a fork down to the roots and cut off with a knife. The pruning of these trees on walls consists of taking out dead and worn-out branches to make room for young shoots left their whole length at the summer pruning. Shorten the longest of these a third of their length, cut out all old "snags," and shorten and thin out spurs.

Advice on Peach trees will be given in a later article.

G. NORMAN.

LATE WHITE GRAPES.

I have just placed my late white Grapes in water for keeping, and "J. C. T.'s" note at p. 34 is most opportune. I have Vines of Lady Hunt, and planted it on account of its thick skin and lateness, but somehow it fails to keep as long as I could wish. Probably this may be owing to various causes, such as too early ripening or other defects in culture, but so far I have been unable to keep this variety as well as the Trebbiano. One difficulty with this variety is its close, compact build, as even with ample thinning the berries spot badly and decay more quickly than one would expect. This season I intend to give this variety different culture, and by so doing may have better fruit at the time needed. If its season can be extended it will be of great value, as we have so few late white Grapes. As is well known, Trebbiano cannot be relied upon after next month, as the berries, though good, decay at the footstalk. I note "J. C. T." does not include the White Lady Downe's in his list of late white Grapes, and it is surprising how this variety has dropped out of cultivation. The variety I grew was poor indeed, but I believe there are two kinds. It would be interesting to know if growers find it reliable.

G. W. S.

[This note has been unavoidably held over.]

PROPAGATING POLYGONUM BALDSCHUANICUM.

As previously stated, this has proved difficult to propagate, yet anyone possessing an old plant may well try the following method detailed last spring in the French journal *Le Jardin*. Its increase there is spoken of thus: "After trying various methods with but little success, we resolved some weeks ago to take the woody shoots of the preceding year, and treat them in the same way as is done in the case of the Vine when propagated from eyes. The branches were cut up into lengths and laid flat in well-drained pans of soil, with a layer of silver sand on the top, the whole being placed on a moderate hotbed. Slightly burying them in the sand by simply pressing them with the fingers and kept sufficiently moist, these cuttings gave very good results, especially those that had been made rather long—that is from 8 to 10 centimetres in length." T.

THE WHITE CORYDALIS.

I wonder how many people grow *Corydalis cava albiflora*? Not many, I expect, as a large firm of florists, who supply most things, had "to get it for me." It always seems to me worth looking for in spring. The delicate green prettily-cut leaves and panicles of creamy-white flowers, interspersed with reddish-brown bracts, form a pretty combination. It seems to prefer a moist, shady situation in vegetable soil. Care must be taken to mark where it grows, as it dies down early in autumn.

Woolside Park.

T. J. W.

NOTES OF THE WEEK.

Forced Daffodils. Mr. Jenkins, Hampton Hill, sends us some blooms of Daffodils, double *Telamonius* and some of the early Trumpets, apparently *Priniceps*. The colour of the blooms is quite equal to the normal colouring out of doors, that of *Telamonius* being specially rich, and the foliage is tall and stout.

A small Narcissus. I enclose a small *Narcissus* which began to flower, as usual, about January 20. It is not in form exactly the same as *N. minimus*, and always precedes it by about three weeks. It was a kind gift to me from Mr. Barr after one of his expeditions to Spain. — J. H. ARCHER-HIND, *Cumbria-shire, Devon*.

[The flower is *N. minimus*. Imported bulbs of this *Narcissus* vary much both in size and form of bloom as also in the actual time of flowering. In its native habitat *N. minimus* increases from seed, and hence its variable character. — Eds.]

Ulmus alata. — Among deciduous trees which are particularly noticeable during the winter when devoid of foliage is this, the Winged Elm of the United States. Both its specific and popular names are derived from the peculiar corky excrecence which is disposed on either side of the stem, and to such an extent that at a little distance the smaller branches appear to be at least two or three times their actual stoutness, which on closer inspection is found to be caused by the corky ridges on the bark. It forms a medium-growing tree, the head being composed of long wide-spreading branches, which in conjunction with its winged bark gives it a very distinct appearance. It is a native of the Southern United States, and was introduced in 1820. Its timber is said to be valuable, but in this country its principal claim to recognition is the peculiar corky bark. — T.

Pear Broompark. To look at this little Pear, with its dumpy, Apple-like figure and its rough-feeling, coarse-looking brown skin, one would hardly think that its unattractive exterior could be the covering of so truly dainty a morsel as there is within. The flavour is indeed first-rate, recalling in an idealised manner the excellent taste that a good stewing Pear develops in cooking with the added attraction of the freshness of the perfectly ripened raw fruit. The toughness of the thick skin is shown by the fact that we received some of these Pears, just ripe, in a parcel without box or any protective packing material, but merely done up in squarish shape in a sheet of newspaper, tied across both ways with string in the usual way. They arrived quite unharmed thus packed by the sender, who knew what he was about, but we should scarcely have dared to pack a sample of Potatoes thus. This capital little fruit is thus described in Dr. Hogg's "Fruit Manual": "Fruit small, roundish, obovate; skin yellow, sprinkled with cinnamon-coloured russet; eye small, dry and horny, set in a slight depression; stalk an inch long, curved, and inserted in a slight cavity; flesh yellowish, melting, juicy, and sugary, with a rich musky flavour. An excellent dessert Pear; ripe in January. The tree is very hardy and vigorous, an excellent bearer, and succeeds well either on the Pear or Quince stock. It was raised by Mr. J. A. Knight, and first produced fruit in 1834."

Flowers of *Phaius grandifolius*.

The enclosed flowers are from seedlings raised by crossing *P. grandifolius* with *P. Wallichii*. My seedlings that have flowered have all shown improvement both in flower and vigour to the parent plant. I have now about fifty spikes opening their flowers in various stages of development and carrying from twelve to eighteen blooms and buds like those herewith enclosed. Spikes of these arranged with foliage of *Iris botanica* are very acceptable at this season of the year when tall flowers are none too plentiful. The spikes are very enduring in a cut state. I often wonder the *Phaius* are not more grown considering their usefulness and simple requirements. They can be grown and flowered in from 9 inch to 5 inch pots, in which they are well adapted for room decoration. Cultural requirements are as follows: I always pot them

after flowering and when new growths are well started, using good fibrous peat, loam, sphagnum moss, with the rough charcoal siftings from the burnt rubbish heap freely worked amongst the potting material as the potting proceeds. They should be given an ordinary stove temperature. Be very sparing with the water in the early stages after potting until growth is vigorous and the plants are making fresh roots, when they will require to be kept moist. When the flower-spikes show themselves give the plants weak cow manure, and they will do well. *Phaius Norman* and *P. Cooksonii* respond well to the same treatment. The latter variety with me throws two spikes from strong growths. — JAS. R. HALL, *Four Warren, Cobham, Surrey*.

[Very richly coloured flowers of this *Phaius*. — Eds.]

Galanthus Elwesii var. *Whittallii*.

— One is pleased to see this fine Snowdrop figured so artistically in *THE GARDEN* by Mr. Moon. As I had the pleasure of suggesting that the name of one of our kindest friends should be attached to this Snowdrop of his introduction, one feels pleased to be in a position to say that this season it quite bears out the promise it held out to us last year — the first since it was sent from Smyrna by Mr. Whittall. It is truly a fine plant, with its great leaves and fine bold flowers. The only difference it shows is its blooming rather later, when compared with others, than last season. This did not surprise me, as I have often found that imported Snowdrops flowered earlier the first season than in succeeding years. Mr. Whittall's Snowdrop is well worth having, and it appears to be doing well here in both moist and dry positions. — S. ARNOTT, *Corsythorn, by Dumfries, N.B.*

Protea cynaroides. Among the popular indoor plants of fifty years ago the various Proteas, including the Banksias, Dryandras, and Grevilleas, as well as numerous species of the genus *Protea*, occupied a prominent position, but are now rarely met with. The subject of this note, *P. cynaroides*, is one of the showiest of the Proteas, and a good example of this is just unfolding its blossoms in the succulent house at Kew. Planted out in an unshaded structure it succeeds well, and forms either in bud or in flower an attractive object. The pinkish flowers, which are borne in a terminal head, are surrounded by large bracts, suggesting the Globe Artichoke, hence the specific name of *cynaroides*. These bracts are more or less silvery, and this is particularly noticeable before the flowers open, as in that stage the bud resembles a whitish cone. This *Protea* is a native of that continent towards which so much attention is now directed, viz., South Africa, where the name of Sugar Bush is applied to different members of the genus. In this country it needs the protection of a greenhouse, a soil composed principally of sandy peat, a liberal water supply, and above all thorough drainage. — T.

Narcissus monophyllus. Among the greenhouse plants which are in blossom at this early season of the year I think this little Algerian *Narcissus* takes a high place. It is just now among flowers in the greenhouse what *Cyclamen coum* is in the open border, and is sure to be an object of great attraction. Its chalice-shaped blossoms are borne on Rush-like scapes of a few inches in height, and their whiteness cannot be exceeded. For some reason or another it used to have the reputation of being an excessively difficult plant to grow, so difficult in fact that it was scarcely worth while to take much trouble about it. I remember a long time ago my old friend Mr. Rawson, of Windermere, sent me a long memorandum which contained all the information which he esteemed to be desirable on this head, and no doubt all he said was perfectly correct; but I think the gist of it might have been reduced to one single point, and if care be taken about that, the rest will follow as a matter of course. *Narcissus monophyllus* will stand very little watering, if, indeed, it will stand any at all, before root action has begun. The roots must be somehow coaxed into action before anything like safety can be proclaimed, but when this is done there is no more occasion for any

special anxiety about watering or anything else. At any rate, I have now grown *Narcissus monophyllus* for a good many years, and its cultivation has long since become a piece of ordinary routine. It is highly attractive in my greenhouse just now. As my pen is in my hand I may perhaps as well say that *Niphon Histro* is coming out well in the open border, and, of course, *Iris stylosa* is sure to enliven the dead season of the year. — HENRY EW BANK, *St. John's, Ryde, I. of Wight, Jan. 20.*

Primula sinensis fimbriata. — We have received specimen blooms of the beautiful strain of Chinese *Primulas* raised by Mr. William Bull, 536, King's Road, Chelsea. The flowers are fine as regards size and extremely pretty. Novelty among them are: Comet, bright magenta; Countess and Blushing Beauty, both of a delicate pink colour, the latter being semi-double.

Moræa iridioides Macleanii. — Can any of your readers who may happen to have cultivated the above plant suggest any approximate limit to the longevity of the flowering scape? My plant threw up a scape in the summer of 1897; this bloomed (in a greenhouse) at Christmas, again in the summer of 1898, and has continued ever since to produce blooms every three or four months. I am not aware of any *Irid*, or, indeed, of any soft-wooded plant, that has the same peculiarity. This is an extremely beautiful *Irid*, or *Iris*, for all gardening purposes. Except in the matter of complete hardiness, it is an *Iris* pure and simple. The falls are milky white, the standards (which — the plant being a *Moræa* — are spreading and not erect) are yellow, and the stigmas bright mauve-purple — a perfect tricolor. *M. iridioides Macleanii* — also known as *Dietes Macleanii* — is a hybrid. — J. C. L.

Begonia Haageana. — In any selection of *Begonias* for autumn and winter blooming this is worth a place, as it is in every way a good decorative plant, being well worth growing for the sake of its foliage alone, and when in addition the massive clusters of blossoms are produced, its ornamental qualities are greatly enhanced. The flowers are of a blush tint, with conspicuous red hairs on the outside of the sepals. Though spoken of as an autumn and winter-blooming plant, it might almost be regarded as perpetual flowering, for blossoms are also produced at other seasons. Treated liberally it will form quite a bushy specimen 3 feet or 4 feet high and as much through. It succeeds best in the temperature of an intermediate house, as in the stove it is apt to become rather weakened. This *Begonia* was introduced from Brazil in 1887, and at first a certain amount of confusion prevailed between this species and *B. Scharfiana*, which is somewhat similar, but *B. Haageana* proved to be the better garden plant of the two. — H. P.

Adonis amurensis. This species of *Adonis*, which has not long been introduced, has proved to be the first hardy herbaceous flower to open in my garden in this the last year of the nineteenth century. It has beaten the *Aconites* even, and, in fact, every bulbous plant except a solitary specimen of the new *Galanthus Whittallii*, which opened about four days before, on January 18. There is no denying the fact that January is mid-winter, and that, as Count Smolrtork said, "he surprises within himself" some of the worst potentialities in the way of weather; consequently it may reasonably be doubted whether flowers coming into bloom in the open at this season can be of much value. The wind and the snow, however, are more surely tempered to certain species of *Ranunculaceæ* than they are even to stony larks, and *A. amurensis* appears to be quite as weather-proof as are the *Hellebores* or even the *Aconites*. How far any of the species of perennial *Adonis* can be said to be "distinct" is a question that depends a good deal on the way you look at it. All have glistening yellow flowers, the apothecis, so to speak, of the common *Buttercup*, and all have very similar finely-cut foliage. The flowers also vary in size, but they do this very often in plants of the same species, which is a mere matter of soil or cultivation; on the other hand, they certainly seem to differ in the matter of cultural requirements. *A. pyrenaica*, which is generally admitted to be the finest

variety, appears to many of us to be especially difficult to establish or keep. I remember years ago noticing a remark of the late Mr. J. Wood that he considered the growing of this species to be the crux of successful cultivation of alpine plants. In this I agree with him, although it disposes of my own claims in this respect. On the other hand, I have observed that some of the nurserymen in their catalogues seek to enhance the attractions of this plant by adding that "it is very easily grown." As this is otherwise unnecessary and gratuitous, it must be assumed that they, at any rate, have always found it so. There seems to be no special difficulty in the culture of *A. amnensis*, although, inasmuch as bought plants are not likely to be very strong, it should be looked after when first planted, for slugs are fond of it. The common *A. vernalis* is, no doubt, the easiest to manage in a general way. *A. volgensis* is, I believe, merely a variety of this with somewhat smaller flowers. I do not remember ever having seen it, and I certainly have never grown it. There is, or was, a certain *A. Walzii* in commerce, but I have never seen this either and know nothing about it. *A. amnensis* was figured in vol. lii. of THE GARDEN, p. 6.—J. C. L.

OBITUARY.

THE LATE JOHN FRASER.

So widely known and highly esteemed was Mr. John Fraser, an account of whose life was given in THE GARDEN of last week (p. 70), that we thought a photograph of our late friend would interest many readers of THE GARDEN. He was a thorough horticulturist, and his assistance upon the floral committee of the Royal Horticultural Society will be much missed.

THE LATE J. FRASER.

"ALMOST A CENTENARIAN."

THE FATHER OF SCOTCH GARDENERS.

In all probability the father of Scotch gardeners has passed away in the person of the late Mr. James Fraser, who died at Castlehill, Turriff, on the 18th ult., aged 98 years. Mr. Fraser was engaged by the late Dr. Adam as gardener at Ardmiddle House, Turriff, in the year of the disruption—1843—and for the long period of thirty-three years he conducted gardening operations at Ardmiddle with great acceptance by his employers. The gardens and grounds at Ardmiddle saw many improvements carried out under his management, and during Mr. Fraser's long engagement he served

three generations of the family. It was with great regret that the late Mr. Milne parted with his faithful and trusted servant twenty-five years ago, when Mr. Fraser retired from active duty and took up his residence in Turriff, which just now, by his death, mourns the loss of its oldest inhabitant. Mr. Fraser was a pawk, shrewd, typical Scotchman, and a gardener all over. Locally Mr. Fraser enjoyed a reputation as being an authority on all matters connected with horticulture, and in his day few could outdo him in the art of growing good vegetables and hardy fruits, while from personal remembrance I can speak of him as an expert in the cultivation of Strawberries, Melons, and Cucumbers. The immediate cause of Mr. Fraser's death was a sharp attack of influenza, that deadly enemy of all mankind.

Terrigles, Dunfermline, N. B.

JOHN MACKINNON.

SOCIETIES.

SWEET PEA BICENTENARY CELEBRATION.

The first general committee meeting in connection with the bicentenary celebration of the Sweet Pea was held, by kind permission, in the Horticultural Club Room, Hotel Windsor, on Friday, January 19, when Mr. George Gordon, V.M.H., presided over a very representative gathering.

Business being the purpose of the meeting, no time was lost in speechifying. The chairman briefly alluded to the desire expressed in 1899 by leading amateurs, nurserymen, seedsmen, and market growers that a comprehensive exhibition of Sweet Peas should be held during 1900, together with a conference, one duty of which should be the classification and selection of varieties. This desire led to a meeting in Edinburgh in September last, when Mr. Gordon (chairman), Mr. H. J. Jones, and Mr. R. Dean (secretary) were elected as a preliminary committee to draw up a scheme for the celebration and submit it as early as possible to the general committee. After this brief and formal statement, the chairman requested the secretary, Mr. R. Dean, V.M.H., to read the letters received from the Crystal Palace Company and the Royal Aquarium Company. The former offered to accommodate the exhibition, provide the necessary conveniences for a conference meeting, and subscribe £20 to the prize fund. This being the best offer, it was agreed, on the proposal of Messrs. H. A. Needs and H. J. Wright, that the bicentenary celebration be held at the Crystal Palace, Sydenham, on July 13 and 14, 1900, or as near those dates as could be conveniently arranged without clashing with other exhibitions.

Having settled the place and date of celebration as far as possible, the next point for discussion was the schedule of prizes, of which a preliminary draft had previously been communicated to the vice-presidents and committee. Before the discussion of classes and prizes a list of subscriptions received and promised up to date was submitted by the secretary, amounting to nearly £90. As the whole of the subscriptions received were unadmitted, the committee felt that the success of the undertaking was practically assured, believing that those interested in the most beautiful, useful, and fragrant of annual flowers—the Sweet Pea—would not fail to show their practical sympathy with the committee's efforts as soon as affairs had received definite form. The schedule is a comprehensive one of twenty-eight classes, each with four, and some with five prizes, offered on a most liberal scale. Class by class the schedule was discussed, and numerous minor alterations made. Nineteen open classes are provided for cut blooms, all to be shown in vases, these including classes for forty-eight, thirty-six, and eighteen bunches, and thirteen classes for one bunch of a specified colour or colours. Four classes are limited to amateurs employing either one or no regular gardener, and then there is a division, open to all, consisting of five classes instituted for the purpose of demonstrating the value of Sweet Peas in all forms of decoration known to the florist's art. The total amount offered in prizes in the preliminary schedule exceeds £90, and this comparatively large sum should ensure a display of the most beautiful and instructive character.

Special prizes are invited, but they must, in accordance with the resolution passed at the Edinburgh meeting, be free from any trade conditions. Already several firms have intimated their intention of providing the prizes in certain classes, and at this meeting it was decided to accept Mr. Henry Eckford's generous offer of £15, the sum offered in class one for forty-eight bunches of Sweet Peas in not less than thirty-six varieties, an offer made by the Wem veteran to commemorate the fact that this is the twenty-first year of his work in selecting and cross-fertilising Sweet Peas. Mr. H. J. Jones offer to supply the prizes in class twenty-five, for an ephebe of Sweet Peas, £2 17s., and Mr. R. Sydenham's offer to supply the prizes in two of the amateur classes, amounting to upwards of £5, were accepted and acknowledged. With reference to the rules and regulations for competitors, it is worth while noting that from subscribers of 10s. 6d. and upwards no entrance fees will be demanded, but non-subscribers must pay an entrance fee of 2s. to entitle them to compete in any six classes (subject to divisional schedule regulations), but a further entrance fee of 5s. must be paid if this number is exceeded.

Conference proceedings, subscribers tickets, publication of report, and other matters were referred to, but reserved for final discussion and settlement at the committee meeting to be held on Friday, February 23, by which date the complete schedule, regulations, &c., will be ready for acceptance and immediate publication.

Meanwhile, the committee desires the sympathy and financial assistance of all horticulturists, so that the forthcoming celebration may be made the unqualified success its interest and importance demands. Any surplus funds remaining after the payment of prizes and necessary expenses will be given to the gardening charities. Further particulars can be obtained from the hon. secretary, Mr. R. Dean, V.M.H., Ranelagh Road, Ealing.

ROYAL HORTICULTURAL SOCIETY OF SOUTHAMPTON.

We have received the report and schedule of prizes for the coming summer and autumn exhibitions of this society, which will take place on Wednesday and Thursday, June 27 and 28, and Tuesday and Wednesday, November 6 and 7, respectively. We are pleased to see from the report that the society is in a very satisfactory condition. The adverse cash balance of over £117, with which the society commenced the year, has been so reduced, that the net deficit, allowing for the value of the society's material and one or two outstanding subscriptions, is now practically nil, a position the society has not enjoyed since 1887. The credit balance on the years working amounts to over £97, as shown by the following figures: Net receipts for the year, £54 3s. 6d.; net expenses (not including bonds redeemed), £47 2s. 6d. The hon. secretary is Mr. C. S. Fudge, Heckfield, 17, New Alma Road, Southampton, from whom all information may be obtained.

BRISTOL AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

The fortnightly meeting was held at St. John's Parish Room, Redland, on Thursday, the 25th ult. Mr. C. Lock presided over a large attendance. The meeting was specially interesting by reason of a paper read by a member from the Cardiff Gardeners' Association, Mr. J. Graham. Under the title "Gleanings from a Horticultural Class," Mr. Graham dealt with a variety of subjects, all of great importance to gardeners, such as soil and its constituents, bacteria, thermometers, dew and rain, laying out of pleasure grounds, rocky formation, draining of land, plant diseases, &c. Mr. Graham strongly urged the formation of botany classes in connection with gardeners' associations, claiming that a knowledge of theory was a great help to the practical worker. An exhibit of great interest was provided by Mr. Graham, who showed over fifty dried specimens of British plants. A motion of sympathy with the relatives of the late Canon Anstey was passed. The late canon was a vice-president of the association during his residence at Redland, and took a keen interest in the work from the time of its formation.

ROYAL GARDENERS' ORPHAN FUND.

The annual general meeting of the subscribers to this fund will be held at the Essex Hall, Essex Street, Strand, London, W.C., on Friday, February 16 next, for the purpose of receiving the report of the committee and statement of accounts for the past year, to elect officers for the ensuing year, to elect nine children to the benefits of the fund, and to transact such other business as may arise. The chair will be taken at 3 p.m. The poll will close at 4.30 p.m., after which time no votes can be received. B. WAXNE, Secretary.
S. Dimes Inn, Strand, W.C.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT SOCIETY.

We are pleased to know that this society, held in the famous old council room in the Chiswick gardens of the Royal Horticultural Society, is well supported, and its flourishing condition is due in no small measure to the interest taken in it by the president, Mr. Wright, superintendent of the gardens. The subjects dealt with recently have been "Odontoglossums," by Mr. Hollingsworth, and "Onions," by Mr. A. Dean. The following meetings will take place on February 5 and 22 and March 8 and 22, and those who will give pupils include Mr. McLeod, Mr. Chas. Harding, and Mr. John Fraser.

READING GARDENERS' SOCIETY. CHEMICAL MANURES.

This was the subject of a lecture delivered by Mr. F. W. E. Shrivell, of Thompson's Farm, Tonbridge, at the fortnightly meeting of the Reading Gardeners' Mutual on Monday evening last. The lecturer in an interesting and easy manner laid before the members the results of the various experiments carried out at Tonbridge during the past five years with chemical manures on vegetable and fruit crops, under the auspices of the Permanent Nitrate Committee, who wished to find out whether animal manure could be dispensed with altogether, relying solely on chemical manures. An interesting discussion followed, in which Messrs. Fry, Neve, Pinks, Chamberlain, Burfitt, Alexander, Wilson, Hinton, Lever, and Ager took part. On the proposition of the chairman (Mr. Fry), a hearty vote of thanks was accorded to Mr. Shrivell for his lecture, and to Mr. F. Lever, The Gardens, Hill-side, for staging an exceedingly well-flowered plant of *Gelogyne cristata*. Six new members were elected.

NATIONAL CHRYSANTHEMUM SOCIETY.

The annual general meeting of the above society will be held at Carr's Restaurant, 265, Strand, W.C., on Monday, February 5 next, at seven o'clock p.m., to receive the committee's annual report and balance sheet to elect the president, vice-president, officers, and a third of the committee for the year ensuing, to consider certain alterations and amendments to the rules, and transaction of other business which pertains to the annual general meeting. An important notice of motion has been made by Mr. Thomas Bevan: "That the election of the present general secretary be postponed, and that an advertisement be

inserted in the gardening papers for a properly qualified person to fill the post of secretary at a salary of £100 per annum.

The report of the committee for the past year seems satisfactory. The committee in presenting their report feel they can congratulate the members upon a condition of affairs in relation to the society of a generally satisfactory character. The exhibitions have maintained their high quality without decreasing in extent; the hold of the society upon the numerous provincial and foreign societies affiliated to it is as wide and firm as at any time; the work of the floral and classification committees has been carried out with spirit; the financial position of the society is decidedly encouraging, the balance sheet statement for the year showing a substantial balance in hand, while the assets of the society are of an improved character. The committee recommend that the sum of £50 of the reserve fund, now on deposit, be increased to £100.

The committee note with regret that the incurved, the reflexed, and the Anemone-flowered types appear on the exhibition stages in decreased numbers, though this fact may not, of itself, justify any apprehension that there is an actual lack of interest in the culture of the varieties of these sections.

The vase class was the leading feature at the November exhibition, and made a most imposing display, arousing a large amount of public interest. The competition was numerous and keen, though some who had entered for competition found themselves at the last moment unable to bring their flowers. The large-hearted liberality shown by Messrs. James Green and Nephew in providing such a considerable number of handsome vases free of charge for the purposes of the class was highly appreciated by the committee. At all the exhibitions, miscellaneous exhibits, mainly supplied by the trade, afforded features which enhanced the interest of the various displays, and imparted an attractive variety as well.

It is satisfactory to notice that the competition among affiliated societies for the possession of the challenge trophy is maintained with spirit. Still, it is desirable more societies should take part in the annual contest. The possession of the Holmes Memorial cups appears to continue to fire the ambition of growers, and give occasion to close competitions.

The committee are under a great obligation to their president, Sir Edwin Saunders, for his valuable special prizes; to Mr. P. Waterer for his special prizes for an essay on the Chrysanthemum rust, which failed in its objects; and to other donors of special prizes, which enable the committee in a few instances to introduce special features into their schedule of prizes.

A sub-committee have had under consideration the relation existing between the National Chrysanthemum Society and affiliated societies, and having reported that it is desirable certain amendments be made to the privileges enjoyed by affiliated societies, the committee have adopted the same; and as alterations in the rules are made necessary, such alterations will be proposed for adoption at the annual general meeting.

In November last a deputation from the committee visited Lyons, in response to an invitation from the secretary of the French National Chrysanthemum Society, for the purpose of taking part in an important exhibition of Chrysanthemums; and an interesting account of the proceedings of the same, compiled by Mr. C. Barnum Payne, will be published with the annual report, &c. A very hearty vote of thanks was passed by the committee to the deputation; they at the same time placing on record their belief that the exchange of international courtesies in this and other ways between home and foreign cultivators and lovers of the Chrysanthemum is most desirable, and should be promoted in every possible way.

ANSWERS TO CORRESPONDENTS.

Names of plants. W. H. A. A very good form of Cattleya labiate.

Names of fruit. T. L. 1. Round Winter Nonsuch; 2. Bismarck; 3. Lady Hamaker; 4. D. Vex Spice; 5. White Nonpareil; 6. Knight & Monarch. H. J. P. Round Winter Nonsuch.

TREES AND SHRUBS.

The Rose of Sharon (*Hypericum calycinum*) (R. M. S. STOCKPORT). This is really a low-growing evergreen shrub, but in some positions it is quite common for it to become sub-evergreen in severe winters and thus present a somewhat unsightly view for a short time each year. The plant increases rapidly by means of underground growths, the younger ones being more vigorous than the older ones. As you have a plentiful supply of leaf-mould, &c., you would do well to apply a top-dressing in early spring, as it will be of immense benefit in affording additional stimulus. Remove the dead and useless growths. It is not necessary to cut the plants down to the ground line.

Planting Yew (G. A. M.). In planting Yew trees to form a hedge a very suitable size is well-furnished bushy plants from 2 feet to 3 feet high, and if these are planted 18 inches apart they soon form a dense and effective break. Of course a good deal depends upon the plants having been frequently removed, a practice carried out in all good nurseries, as then their transplanting is done with but little risk. Larger specimens, if suitable and can be obtained, may be employed, in which case a somewhat greater width may be allowed, but it should at most not exceed 2 feet, and unless the plants are particularly bushy, 18 inches distance will be the best. In planting a hedge in two rows a distance of 1 foot to 1½ inches should be kept between them. The plants in the two rows should not be opposite one another, but placed at an angle, as by this means a more

regular hedge is formed. Planting may be done from autumn up to February or March, in which latter, should the weather keep dry, care must be taken that the Yews do not suffer from drought. Clipping may begin the spring following the planting of the hedge.

FLOWER GARDEN.

Spacing and colouring of flower bed. The Rev. R. M. asks our advice both as to the spacing and colouring of a bed he proposes to plant with Stocks and Tufted Pansies. We think it would be better not to distribute the two kinds of plants evenly all over the bed, but to group the Stocks towards the middle, with a thinner outer ring not reaching quite to the edge, and to plant the Tufted Pansies so that they will fill out the edge and run up towards the middle between the thinner row of outermost Stocks. We are not told what the shape of the bed is, but in a round or square or any other solid form, we think that this would be the best way of disposing the plants. A bed of white and mauve in the two kinds of plants would be likely to be prettier than one all mauve. A colour-word such as mauve might cover so large an area of tinting, that it would be quite possible to plant together a mauve Stock and a mauve Pansy that would be inharmonious, though if the colours were rightly chosen they might go together very prettily. This is a case in which it is quite impossible to give a helpful answer without seeing blooms of the plants proposed to be grown together. If Rev. R. M. would care to take the trouble to get from any Pansy nursery several kinds for mauve bloom and to try them for one year with the colour of the Stock he proposes to use, we shall be happy to advise him further if he will send us the blooms of both for consideration.

Sweet Peas sown for succession (REV. R. M.). The quantity of Sweet Peas you think of sowing seems too much for the space. You desire to plant two hedges 6 feet apart in three sections for succession, and to have the kinds arranged in harmonious colouring. If the length is divided in three there would be a one-third section on each side of the space, between the two rows, in flower at the same time. For colouring, row 1, section 1, might have kinds whose flowers are French white (pinky white), pink, cool rose, scarlet and pink and white, or a selection from these. Row 2, section 1, whites and lilacs (Princess May and Countess of Radnor for the lilacs). The next in succession in row 1 might be deep pinks, the dark Boreatton and dark scarlet, and opposite, in row 2, light and dark purples and white. The last two sections could have in row 1 salmon-pink colouring and Orange Prince, and opposite Captain of the Blues, whites, and pale yellow. If, instead of sowing thickly in one drill, each row is of two drills 2 feet apart, and the seeds are placed by hand 4 inches apart in the drills, and mulched after they have made some growth, less seed will be used and the Peas will be much finer. The plants in the double drills should be staked with two lines of spray-leaving towards each other, when the flowers will stand up free. It is important to pick off the overblown flowers so that the plants may not be weakened by forming seed.

INDOOR GARDEN.

Celosias (GHESS). We are pleased to learn that you like Celosias. They certainly rank when well grown as amongst the most beautiful plants, whether in grace, in form, or in colouring, that are grown in gardens. We are very pleased to see that, whilst being of such tender constitution, their time of beauty outdoors is limited, their frequent introduction into bedding displays during July, August, and September adds so much that is pleasing to a style of gardening that needs so much of such added beauty to commend it. But whilst mixed packets of seed give all the rich colours found in the plumes of Celosias, yellow, orange, vermilion, violet, carmine, and other tints, these plumes can only be seen at their best when good culture is given, then a well-branched pyramidal plant is a lovely object. As a rule the middle of March is a good time to sow the seed. Small shallow pans well drained and filled with sandy soil is the best medium, and these, when the seed is sown thinly, should be stood in gentle warmth to induce early germination. When the plants are 1 inch in height they should be picked out into other pans thinly, and then later be put singly into 3-inch pots.

Double Chinese Primulas (ASTON). We do not quite gather from your note whether you inquire concerning double Primulas, such as named varieties, that can only be increased by ordinary propagation, or whether you want to obtain the semi-doubles, that can be raised from seed. In the true double forms the fertile organs of the flowers have been changed into petals. In these semi-double ones that change is limited, and seed-growers can, by splitting the flowers open, find organs that will bear fertilising. Of these there are white, pink, carmine, scarlet, crimson, blue, flaked and other colours, all being, if desired, purchased separately, or may be had mixed. Seed should be sown in May to have strong plants to flower well in November and through the winter. Sow in shallow pans on sandy soil, the seed being just buried, and after gently watering, stand in a warm greenhouse frame, shading it during the day with paper. Plants large enough to lift and prick out thinly into other pans should be ready in about seven weeks, and from these pans they may be got into small pots and so grown on.

KITCHEN GARDEN.

Double digging (F. KREP). This is more simple and there is less work. A space of say 2 feet in width is marked off and the soil taken out two spades deep to the portion of the land where the work is finished and the digging then proceeds; the top spit is placed at the bottom of the space cleared and the second on the top of that, and the same process continues until all is completed. This is double digging, or two spades deep is dug from start to finish. Some cultivators also dig the bottom up before placing the soil, others only remove one spit deep, and the other is dug and left, and double dug in. The proper way is doubtless

to remove the top spit and dig the bottom one. This is a simple, but effective process with poor soils.

Asparagus planting (CHOSE).—Although you can quite easily raise Asparagus plants from seed, yet, if time is an object to you, it will be much better to purchase fairly strong roots now. You can get good ones at about 7s. 6d. per 100, and if they be two years old, then none could be better. That would, if you plant early in April—the best time for such purpose—give you two years' start over seed-sowing now. But, even if you sow seed, do not do so until early in April, as it is unwise to induce the tiny growths to come up until hard frosts have gone. When seed is sown, let it be thinly in drills 2 inches deep and 12 inches apart. Thin out the little plants so soon as high enough to be seen to 6 inches apart in the drills. Hoe freely between them all the summer, and in August give a thin sprinkling of salt to hoe in. If the soil has been worked deep and well manured, the plants at the end of the season will be all the stronger. To make an Asparagus bed in April, get the ground trenched 2 feet deep, bury down a heavy dressing of manure, and fork in a further one with bone-dust on the top, then plant in broad, deep furrows 20 inches apart, the roots being 16 inches apart.

WEATHER IN WEST HERTS.

THE early part of the past week was unusually warm for the time of year, but since the 26th ult. low temperatures have prevailed. On no night did the exposed thermometer show more than 7° of frost. Notwithstanding the cold of the last few days the soil at the present time is at about a reasonable temperature at 2 feet deep, and only 1° colder than the average at 1 foot deep. Rain fell on all but two days during the week, and on the morning of the 28th the ground was covered with snow to the depth of 1½ inches.

JANUARY.

One of the most noteworthy features of this mid-winter month was the frequent changes in temperature. Indeed, during the course of it there occurred three distinct periods of cold, and three distinct periods of mild weather. Taken as a whole, it must be regarded as having been a decidedly warm month. It was not, however, nearly as warm as the two previous Januaries, which proved exceptionally mild. There occurred no cold nights worth mentioning, the lowest reading registered by the thermometer on the lawn showing only 13° of frost. Up to the time of writing, the evening of the 30th ult., there have been only eight days without rain since the year began; whereas the average number for the month is fifteen. The total rainfall amounted to nearly 4 inches, or about 1½ inches in excess of the January mean. It is now fourteen years since we have experienced so wet a January. As affecting the underground water supply I may state that since the winter half of the present drainage year began in October, the fall of rain has exceeded the average quantity for the same four months by nearly an inch—equivalent to about four gallons of rain on each square yard of surface. Although such a continuously wet month, there was more than the usual amount of sunshine.

Berkhamsford, January 30.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editors invite readers to send in questions relating to matters upon which they wish advice from competent authorities. With that object they wish to make the "Answers to Correspondents" column a conspicuous feature, and when queries are printed, they hope that their readers will kindly give inquiries the benefit of their assistance. All communications must be written clearly on one side only of the paper, and addressed to the EDITORS of THE GARDEN, accompanied by name and address of the sender.

The Editors welcome photographs, articles, and notes, but they will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, they will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editors ask that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editors will not be responsible for the return of artistic or literary contributions which they may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Edited by MISS JEKYLL and MR. E. T. COOK

THE ROYAL HORTICULTURAL SOCIETY.

THE report of this society for 1899-1900, which will be submitted to the annual meeting on Tuesday afternoon next, displays a straightforward, honest policy of advancing true horticulture in our land; and so long as this is the watchword, the society will prosper. It would be a disgrace if it failed to win support from horticulturists of all degrees when endeavouring to set forth the principles of gardening and scientific pursuits. The old and evil days of elaborate gardens for fêtes and amusements generally are, we devoutly trust, for ever past, and certainly during the last few years the society has pursued the course of true horticulture, and for this satisfactory condition of affairs, this solid foundation upon which the structure now rests, we must thank those who during troublous times have held firmly the reins of office, guiding the society through a quagmire of distrust and pessimistic belief in its future. We remember well those days; the society was almost a derelict, and many who loved it well believed that its days were numbered, or it not numbered, that a new organisation must be raised up upon the ashes of its predecessor.

Those who are interested in this splendid organisation, knowing that it represents horticulture in this country with an influence even beyond the sea, rejoice greatly in the report that has been prepared for the meeting on Tuesday.

We refer to it prominently on this occasion believing that the society deserves hearty support from horticulturists, and for its future welfare we have nothing but good wishes if it adheres to the present satisfactory policy.

Several features of the report deserve close attention. One is the new experimental garden, and the "acquisition of a new garden in the place of Chiswick" is one of the projects for celebrating the centenary of the society, which will occur in March, 1904. The celebration is already arousing interest, and this departure of seeking fresh fields for experimental horticulture and trials of novelties is excellent. It displays the true gardening spirit. In the old days at South Kensington some wild scheme, notable for its absence of anything concerning horticulture, would have been put forward to celebrate a great epoch in the history of the organisation. To encourage experiments and trials is to promote a love and interest for horticulture and assist the amateur in his selections of flowers, vegetables, and fruits by sifting out synonymous kinds and those not worthy of culture. A garden in the country, removed from smoke or fog influence and from the overshadowing of houses, is essential, and we look forward to the future, as the Royal Horticultural Society without a good garden would lose much of its charm and utility. The council are taking steps at once to ensure co-operation, and mention that "a garden for experiment and trial is an absolute necessity. Chiswick has recently become so surrounded with buildings and the atmosphere so heavily charged with smoke, that not only has the difficulty of cultivation enormously increased, but it is feared that the results obtained from the trials are rapidly ceasing to be reliable. It is therefore proposed to issue an appeal to all the Fellows, and to raise a fund for the purchase of a more suitable site for a garden in memory of the first hundred years of the society's existence." We may remark that the garden should not be many miles from the metropolis and in a convenient district for members and committees to attend for judging the trials, which will probably be extended under the new conditions, and the garden should provide a school for students who wish to follow some branch of horticulture as a means of livelihood. "The council wish to call attention to the good work being done at Chiswick under Mr. Wright's superintendence, not only in the garden, but among the students," and Mr. Wright reports that "The demand for energetic, trustworthy young men from

Chiswick is rapidly increasing; there is no difficulty in placing each in good situations, our supply being unequal to the demand, but they must all be workers."

The fate of the fruit show, held annually at the Crystal Palace, will hang in the balance unless the Fellows betray keener interest in it than exists at present. This annual representation of British-grown fruit is of greater importance than a mere show; it should stimulate greater enthusiasm in an important branch of industry, and become an object-lesson with far-reaching results. The report says, and with truth: "As an object-lesson in British fruit cultivation this annual show stands unrivalled, and is of national importance. Those who have visited it from year to year cannot fail to have been impressed by the wonderful advance which has been made in the quality of the hardy fruits exhibited, and as the importance of fruit growing in this country cannot well be over-estimated, the council invite Fellows and their friends to support them in their efforts to maintain and improve this exhibition by visiting it and subscribing to its funds, for it cannot be too widely known that the continuance of the show is absolutely dependent on at least £100 being raised by subscription each year towards the prize fund. The show involves the society in a very large expenditure without the possibility of any financial return. The council have, therefore, established the rule that they will not continue it unless sufficient interest in it is taken by Fellows and their friends to provide £100 towards the prize fund, and this will in the present year (1900) be even more important than heretofore, as the directors of the Palace have signified to the council that they feel compelled to decrease their contribution by £50. A glance at the list of subscribers will show how small has been the interest taken by the bulk of the Fellows. The council would point out that this is not a local show with a few large prizes, but that a multitude of small prizes have been arranged in order to secure the best fruits in each section; special prizes have been allotted to market growers, and counties have been grouped in such a way that growers should not have to compete with exhibitors from localities more favoured by climatic conditions. These points will be still further extended should sufficient financial support be forthcoming."

It is pleasant to record that the exhibition held in the Temple Gardens, by kind permission of the Benchers, retains its popularity, and that the last show was "as successful as ever; it is

a matter of satisfaction to the council to find that this meeting is now universally acknowledged to be the leading horticultural exhibition of this country." Fashion, of course, is as fickle as the weather, but we hope she will continue to smile benignly upon this beautiful annual display of flowers and fruits, showing British skill in culture and hybridisation. To the uninitiated into the mysteries of plant raising and hybridising to develop new departures this exhibition is a glorious feast of colour and perfume, and nothing more, but the connoisseur knows that it is a manifestation of new plants, Orchids, indoor flowers, Roses, and so forth from the nursery gardens of England and abroad.

The hybridisation conference held in July last in the Chiswick Gardens was a distinct success, "not only for the value of the papers read and communicated, but also for the pleasant opportunity it afforded for the meeting of horticulturists from all parts of the world." We are pleased to know that the report of this conference will form a volume of the society's valuable journal. Such a record is of immense scientific importance.

The question of the legality of some of the bye-laws which since the "great revival of the society in 1887" received consideration, is now practically settled. A strong desire was expressed to throw off the mesh of South Kensington entanglement inseparable from the existing charter. "There appeared to be only two alternatives: either to abide by the existing bye-laws, or to petition Her Majesty to grant a new charter. The expense involved in the latter course has hitherto been an obstacle, but at the beginning of the past year (1899) the condition of the society's finances appeared to the council to be such as to warrant a petition being made to Her Majesty for a new charter, and a considerable part of the year has been employed in drawing it up. The petition to Her Majesty and a draft of the new charter were submitted to a general meeting of the society held on June 21, 1899, and were unanimously adopted and ordered to be sealed with the society's seal and presented to Her Majesty the Queen. The council have much pleasure in announcing that, on the advice of the Privy Council, Her Majesty acquiesced in the petition, and on November 14 signed the supplemental charter and ordered it to be sealed with the Great Seal of the Kingdom."

The council "fully recognise the advantage of the society possessing a hall of its own in which plants, flowers, and fruits can be seen by the Fellows under more favourable conditions as regards light and space," and ask for suggestions. This important matter is in the hands of the Fellows and all interested in horticulture in this country. It is idle to condemn the present building as dimly lighted and comfortless. It must remain so until some scheme can be thought out for obtaining the "Hall of Horticulture" which has yet to become a reality. Horticulture is pursued as ardently, more so probably in this land than in any other country of the world, and its great society is housed in a drill hall admirable for volunteers, but not

for the interesting fortnightly gatherings which attract amateurs, gardeners, and nurserymen from the length and breadth of the British Isles. These meetings have become in the truest sense meetings of all interested in horticulture, and neither dim light nor uncomfortable surroundings damp the ardour of visitors or committees.

It is satisfactory to know that the Lindley Library has not been forgotten, and the books are now enclosed in glass-fronted cases to preserve them. We wish more use were made of this valuable storehouse of horticultural and botanical literature.

To the roll of those earnest horticulturists and botanists, Fellows of the society, who have crossed the silent stream, many names honoured in the world of horticulture and science have been added during the past year. Amongst those whose work has finished are recorded the Duke of Westminster, president of the Gardeners' Royal Benevolent Institution; Sir E. Frankland, Lady Howard de Warden, General Berkeley, Major Mason, Mrs. Milne-Redhead, Mr. T. Francis Rivers, V.M.H.; Mr. Malcolm Dunn, V.M.H.; Mons. Henry de Vilmorin, Mr. S. Courtauld, Mr. T. W. Girdlestone, Mr. J. T. Saltmarsh, Mr. W. Protheroe, Lord Penzance, Sir Henry Tate, Bart., Mr. John Lee, Mr. Alfred Ontram, Mr. James Martin, Mr. S. Spooner and others.

May the society prosper in the future, and increase tenfold its usefulness in promoting a love for gardening and the great horticultural industry of these isles. Its management is in strong hands, and whilst true horticulture is followed, free from anything likely to revert to a former unfortunate policy, then all will be well, and the centenary celebration mark the strongest epoch in its long life.

A HEDGE-BANK GARDEN.

It often happens that a garden is bounded on some side by a hedge-bank, such as is the usual division between fields in many parts of the country. Where this is the case there is an opportunity for treating it as garden space in several different ways. The special way that best suits the individual case will be determined partly by the aspect, partly by the soil, and a good deal by what growing things the hedge may already contain.

A case that lately came before us may be taken as an illustration, and may be the more useful in that it was desired to treat the whole hedge on both sides.

The bank had formerly been the extreme limit of the garden, but the owner, having bought a field beyond, had the happy idea of taking a strip off the field a few yards wide and planting a Holly hedge, of laying down turf between this and the hedge-bank, and of converting the bank into a garden of rambling flowery growths.

On the garden side for the first 150 yards it is flower garden; for the rest of its length, a rather longer stretch, it is kitchen garden. This side there will also be a turf walk extending the whole length. Where pleasure garden ends and kitchen garden begins there will be partly a screen of Roses and other pretty things to hide the vegetable ground, and partly some of the handsomer of the kitchen garden plants, such as Globe Artichokes and Rhubarb, and dwarf fruit trees.

The first thing to consider in the conversion of the hedge is to decide what growths are in it already that can be left and utilised. For the most part the bank is rather bare and scraggy. There are a few poor Hollies, some Whitethorn scrub and some Blackthorn. At the kitchen garden there are one or two Elms, not good-looking in themselves and serious robbers of the garden. The Elms are therefore condemned and will be grubbed down. This will pull the bank right down where it occurs, but at one such point a way through is wanted, so that the opening will come in handy, and in the other places the bank will be rebuilt with turf sods. It is well not to disturb the sides of the bank more than can be helped, so that they will only be attacked with any degree of vigour where they harbour Nettles and bad patches of Couch Grass and strong establishments at the base of deep-rooting Docks. Then we examine the top and dig it deeply wherever it is clear of bushes, but not so near the edge as to weaken the shoulders, except at a few points where it is distinctly desirable to make a break in the general regularity.

As there are already Thorns and Hollies, and as it is desirable that the bank shall present some kind of unity of solid foundation, for the better display of the more ornamental planting, we plant more Holly, Thorn and Blackthorn, and with them a fair quantity of Cherry Plum. Towards the further kitchen garden end some common Elders will do well and look handsome. The Thorns and Hollies are not planted in a straight row, but in groups, breaking here and there into the shoulders and even the sides of the hedge.

Now we have to consider what are the most suitable of the many beautiful things that can be grown in such a place. Foremost will come the Cluster Roses of the Ayrshire and Semper-virens and allied groups, and of these probably the best of all are the Garland Rose and Dundee Rambler, both loving a place where they can fling out their long flower-laden branches. Rosa lucida, of more bushy growth, is also a capital bank plant, and Scotch Briars must be planted freely. Both of these pretty things, though they appear at first to make little growth, are feeling their way underground, and within two years they will have forced their strong suckers through the sides of the bank; and while their running roots help to bind it together, their pretty heads will hang out and adorn the space almost to the ground level with a surprising quantity of bloom. These are planted so as to join in with some of the White thorn groups, so that in winter they shall all show a delightfully related mass of comfortable colouring of warm pinkish-purple and rosy-brown, merging into a top and shoulder planting of Berberis Aquifolium. This also will in time grow through the sides of the bank. As brilliant incidents in this region will come some Forsythia suspensa throwing out their long flower-laden sprays over and among the stiffer branches of the dark Barberry. Then will come a group of Pyrus japonica and a good stretch of Japan Honeysuckle and Clematis Flammula, two plants that grow through and into another in the happiest fashion. Two Brambles will be conspicuous ornaments in our hedge: the Parsley-leaved with its bountiful crop of fruit, and the double-flowered, both pink and white.

These will want quite a long stretch of space. Then in order to break what might be a monotony of trailing growths we must have something of bushy and upright habit. So then we get Gorses and Brooms. One side of the bank faces south-east, and for the greater part of the day is in full sun. Here we must not forget the beautiful Rosa Wichuriana, probably

the best of the sun-loving trailers among Roses, delighting in a warm place where it can hang over and make a living curtain of neat glossy leaf and clear-looking white bloom. A Guelder Rose or two will be fine in the bank, and if a good length of it has the common Traveller's Joy (*Clematis Vitalba*) running over the Thorns and billowing about on its own account, it could scarcely be clothed in any more becoming garments.

The bushes and plants named will be quite enough, when well grown, for a length of bank of 300 yards or 400 yards. Many more plants could be named, but in such a planting a certain restriction in the number of kinds will give much better plant-pictures. Some other kinds of plants would be added, such as a few of the bolder of the hardy Ferns, at the foot or lower parts of the cool sides, and successional sowings of Foxgloves and the best Mulleins, also on the shady side, and Belle-

bores, Columbines and Primroses, while at the bank's sunny foot Acanthuses would be happy and most of the Flag-leaved Irises.

Such bank gardens should be more often made and planted, for there is no end to the beautiful pictures that may be designed and enjoyed, to say nothing of having all the delightful things within easy range of sight and scent, and of presenting the added interest of flitting of butterfly and nesting of bird, also at the most comfortable and convenient of observation levels.

In addition to a judicious planting of double and single Gorse and Broom, common Gorse seed and that of the wild yellow Broom and the white one from Portugal should be sown. In three years' time these sown plants, having thrust in their deep roots without the check of transplantation, will probably catch up and even overtake the planted ones of the same kind.

Clerodendron trichotomum. I should say that those who complain of this plant for not flowering, lack patience. It will not flower till well established, but it flowers and fruits delightfully in Bath, and so it does here. H. ELLACOMBE, *Bilton Vicarage, Bristol.*

NEW AND RARE PLANTS.

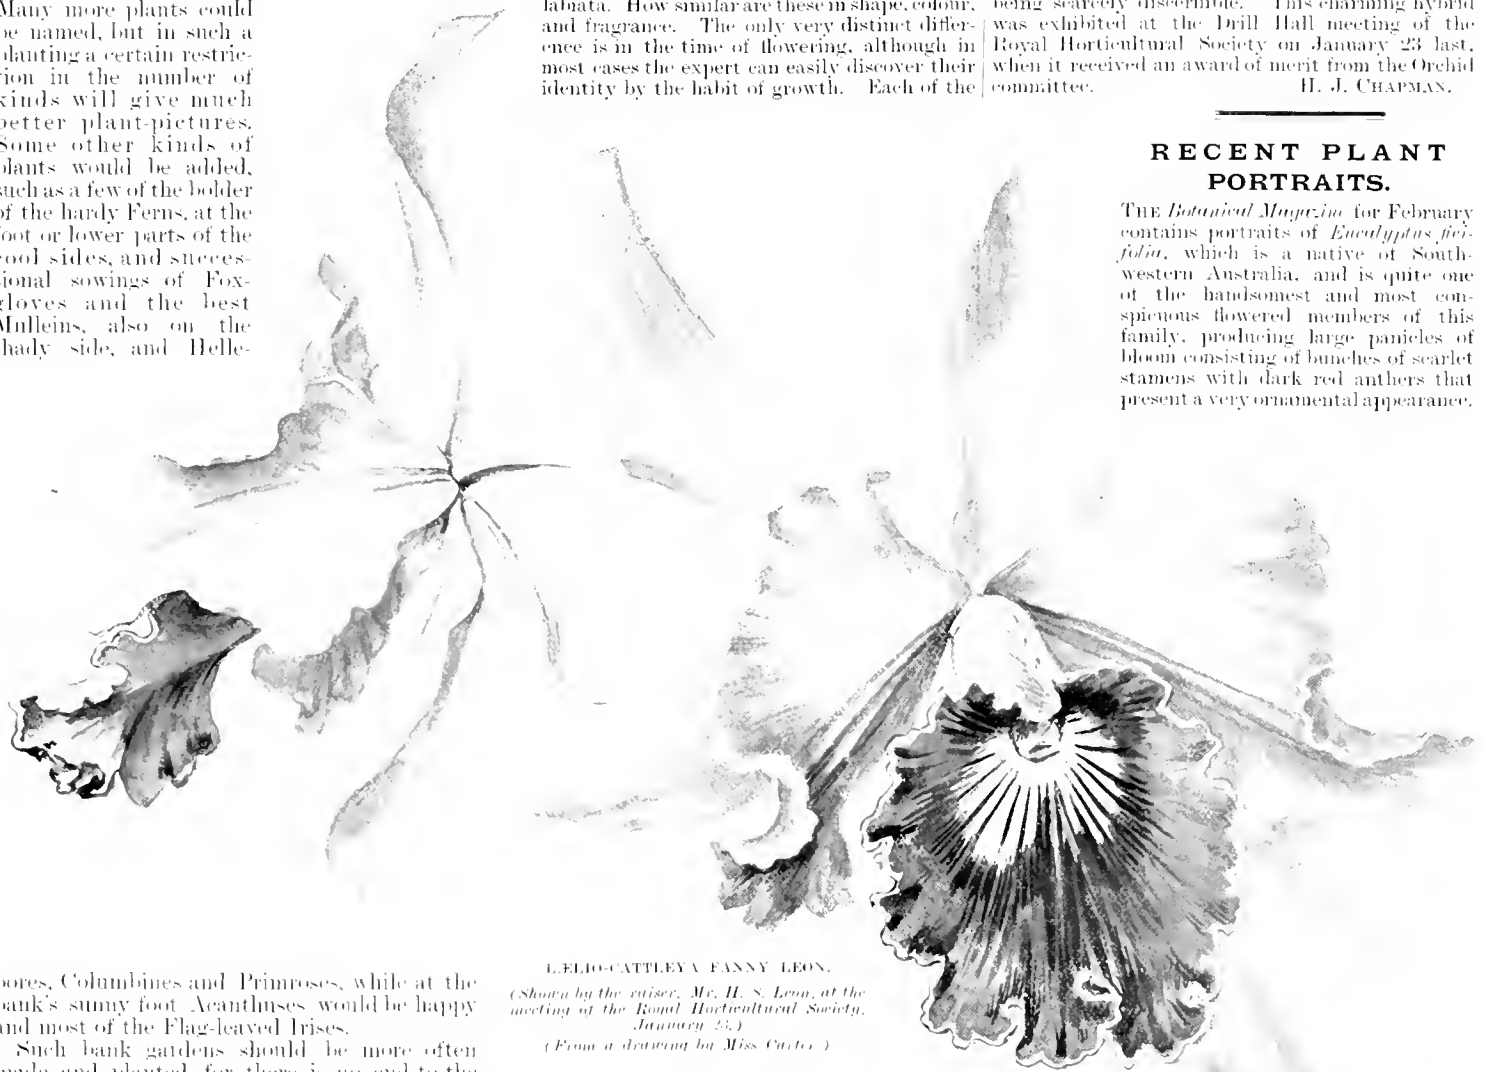

LÆLIO-CATTLEYA FANNY LEON.

IT is not surprising that certain hybrid Cattleyas and Lælio-Cattleyas resemble each other. There is a very fine dividing line between many of the species belonging to the *C. labiata* section, and these are all fertilised with one particular variety of another section. Take for example *Cattleya labiata* Warnerii, *C. l. Gaskelliana*, and the old autumn-flowering *C. labiata*. How similar are these in shape, colour, and fragrance. The only very distinct difference is in the time of flowering, although in most cases the expert can easily discover their identity by the habit of growth. Each of the

The dorsal and lower sepals are each about 3 inches long, upwards of 1 inch broad, deep rosy lilac, becoming lighter at the base. The petals are as long as the sepals and 2 inches broad, somewhat crisped on the margins, and deep rosy lilac. The finely-shaped lip, 2 inches across, is wholly of deep crimson-purple, with darker crimson veenings, and having an almost white-crested margin on the front lobe. The side lobes are similar to the front lobe, shading to white at the base. Through the base of the throat there is a suffusion of deep orange, which is prominently lined with bright purple. The habit of growth shows largely the characteristics of *Cattleya labiata*, the influence of the other parent being scarcely discernible. This charming hybrid was exhibited at the Drill Hall meeting of the Royal Horticultural Society on January 23 last, when it received an award of merit from the Orchid committee. H. J. CHAPMAN.

RECENT PLANT PORTRAITS.

The *Botanical Magazine* for February contains portraits of *Eucalyptus ficifolia*, which is a native of South-western Australia, and is quite one of the handsomest and most conspicuous flowered members of this family, producing large panicles of bloom consisting of bunches of scarlet stamens with dark red anthers that present a very ornamental appearance.

LÆLIO-CATTLEYA FANNY LEON.
(Shown by the artist, Mr. H. S. Leon, at the meeting of the Royal Horticultural Society, January 23.)
(From a drawing by Miss Carter.)

above-mentioned Orchids has been used with *Lælia purpurata* in the production of the three following hybrids, viz.: *L. C. eximia*, *L. C. Violetta*, and *L. C. Bella*. It would be exceedingly difficult indeed for the most enlightened of our Orchid experts to distinguish either of these with any degree of certainty. These remarks also apply to the closely allied hybrids that have been procured through the influence of *Lælia crispata*. I should not have gone into this detail had it not been for the fact that many good judges doubted the parentage which Mr. Hislop gave at the time he exhibited the subject of the accompanying illustration, *Lælio-Cattleya Fanny Leon*. It was raised in the gardens of Mr. H. S. Leon at Bletchley Park from the intercrossing of *Lælio-Cattleya exoniensis* and *Cattleya labiata* autumnalis. It is, therefore, a secondary hybrid, and there is no doubt that it bears a considerable likeness to some of the above hybrids derived from the *C. labiata* group. *L. C. Fanny Leon* is a handsome hybrid, flowering in the depth of winter,

Lomatia longifolia is a native of South-western Australia. This is also known under the synonyms of *Embothrium myricoides*, *E. longifolium*, and *Tricondylus myricetobus*. It is an evergreen shrub or small tree, producing bunches of white flowers with narrow reflexed petals and a golden tip to each. It flowers annually in the temperate house at Kew in July.

Platanus lanceifolia is a native of Asia Minor, and is also known as *P. imbricata*; it is an exceedingly handsome Sage with large and conspicuous golden yellow flowers.

Arisaema flavum is a native of the Western Himalayas, and is also known under the synonyms of *A. abbreviatum*, *Dochata flava*, and *Arum*

flavum. It is described as a remarkably variable plant, but its flowers are small and inconspicuous and of merely botanical interest.

Iris obtusifolia is a native of Persia, and is an extremely handsome new species nearly allied to *I. lutescens*. It has large pale yellow flowers with a deep gold beard on the inner half of the fall. It bloomed for the first time in the bulb house at Kew in 1899.

The *Revue Horticole* for February contains a portrait of a well-flowered bunch of the lovely little gentian-blue Chilean Crocus named *Tecophyton cyanococcineus*, which, owing to its culture and requirements being but imperfectly understood, is as too seldom seen in our gardens.

The February number of *Revue de l'Horticulture Belge* contains a portrait of *Eulophia Lubbersiana*, a curious little Orchid with small and inconspicuous flowers of merely botanical interest, but handsomely variegated foliage, which may commend it to some growers who admire distinctly variegated leaves.

W. E. GUMBLETON.

NOTES OF THE WEEK.

Hyacinthus azureus.—How is it that one so seldom sees a word of praise bestowed on this charming little Hyacinth? There are in my opinion very few indeed of the hardy winter-flowering plants that surpass it for simple beauty. I have now a small clump of it with about sixty heads of bloom and in its way it is very hard to beat. Here in a city garden it is of easy cultivation, flowering year after year without being disturbed, and in fact seems to delight in being left alone. The only care it seems to need is protection from snails when it is first pushing through the soil.—W. S. TILLET, *St. Giles Street, Norwich.*

Hybrid Rhododendrons.—An instance of the attractiveness of some of the javanico-jasminiflorum hybrids of the Rhododendron has been afforded by studs of bloom-trusses exhibited by Messrs. Veitch & Sons, of Chelsea, at the later Drill Hall exhibitions of the Royal Horticultural Society. Of the varieties shown the following were especially effective: *Souvenir de J. H. Mangles*, large truss of reddish-pink blossoms, very striking in colour; *Multicolor Neptune*, crimson; *Multicolor Triton*, pale pink with yellow eye; *luteo-roseum*, faint pink suffused with yellow, large flowers; *Princess Beatrice*, creamy flesh; *debeatum*, shell-pink; *Aphrodite*, flesh-white; *Princess Alexandra* and *Multicolor Mrs. Heal*, two pure whites; *Minerva*, orange; *Exquisite*, canary; *Thetis*, pale orange-buff with reddish centre; and *Ariel*, sulphur-yellow. With the exception of the last-named variety, in which the anthers were of similar colour to the flowers, the whites, pale pinks, and yellows possessed anthers of a much deeper tint than the petals, that, by the contrast they afforded, added considerably to the attractiveness of the flower-trusses.—S. W. F.

Iris reticulata in pots.—Charming as this little Iris is when braving outside the cold winds of early spring, it is also very beautiful when brought on under glass, thus anticipating its usual season of blooming. For general decorative purposes it is most useful when six or seven bulbs are put in a pot 5 inches in diameter. They should be potted in the autumn and placed out of doors, covered with ashes or cocoa-nut refuse, just the same as Tulips are treated, in order to encourage the formation of roots, for without good roots bulbs of all kinds, but especially those needed for forcing, will turn out a comparative failure. As the young growth pushes through the soil the plants should be taken into the greenhouse, where in a good light position their blossoms will develop without any check, and form an uncommon, yet much admired, feature. Forcing in considerable heat, as is often done in the case of Hyacinths and Tulips, will with this Iris end in failure.—H. P.

Correa cardinalis. This, sometimes referred to as the Australian Fuchsia, produces its showy blossoms during the first three months of the year, and was at one time a very popular greenhouse plant, but of late years it has

been less frequently seen, probably owing to the fact that great care is needed for its successful culture. The most suitable compost is good fibrous peat, with a liberal admixture of rough silver sand, and it should be given the same treatment as Cape Heaths. Excesses of moisture or drought must be especially guarded against. The pendulous tubular blossoms of this *Correa* are scarlet, tipped with greenish white, and a good specimen in full flower is a charming object. There are several other species, some much more vigorous than this, but the blossoms are not nearly so attractive. One (*C. alba*) is sometimes used as a stock on which to graft its more showy, but weaker relative.—H. P.

Winter flowering of Yuccas. A note on the above subject appeared lately in these pages. The winter production of flower-spires by the Yuccas, especially by *Y. gloriosa*, is by no means an uncommon occurrence in the south-west. During each of the past seven winters I have remarked instances in South Devon where spikes have been thrown up, though, naturally, the blossoms have not been perfected, in mid-winter. Such cases are, however, rare enough to form exceptions to the general rule, while in the instance cited by your Isle of Wight correspondent, a whole colony appears to have hazarded a similar untimely endeavour. In a cold district in mid-Somerset I have seen Yuccas bearing partially developed bloom-spikes at Christmas.—S. W. F.

Eriostemon cuspidatus.—The *Eriostemon*s are all natives of Australia, and in the days when hard-wooded plants were popular they used to be generally grown. Now, however, they are seldom met with, being obtainable in good condition from very few nurseries. Throughout the entire genus the different members are marked by a strong family likeness, forming effective bushy specimens clothed with deep green leaves, and bearing either white or pale pink blossoms. That with which this note deals (*E. cuspidatus*) is one of the best, the pure white blossoms, nearly an inch across, being borne in great profusion, while a succession is kept up for a considerable time. The cultural requirements are much the same as that needed by the general run of hard-wooded plants, namely, a compost principally consisting of fibrous peat and sand, with thorough drainage. It needs to be kept fairly moist at all seasons, but anything approaching stagnation at the roots will be fatal to its well-doing. Where specimens are planted out in a greenhouse border this is one that can be recommended for that purpose.—T.

Crocus ancyrensis.—This pretty little Crocus has been among the first of the genus to give us its flowers this season. Very welcome have been their bright cones of orange-yellow, which only lack of sun has prevented from expanding to show the interior of the flower, with its orange anthers and scarlet stigmata, some days before January had run its course. This Angora Crocus is small in size, and in this respect may be less prized by some than the larger flowers of an early form of *C. aureus*, which is in bloom at the same time. It is, however, so neat and cheery-looking in a dull time, that it adds much to the interest of a garden even to those who take no special interest in the Crocus apart from the brilliant effect of the large-flowered species or the Dutch forms. Such flowers as *Crocus ancyrensis* form a link between the fine Crocus speciosus, which was figured in THE GARDEN the other day, and the others which come in spring and give so much beauty to the garden.—S. ARNOTT, *Carslown, by Dumfries, N. B.*

Cyclamen coum. I think very few persons will be likely to question the attractiveness of this early alpine flower and its hybrid variety *Atkinsii*, raised by Mr. Atkins, of Painswick. This attractiveness arises from its own intrinsic beauty of flower and foliage, its dwarf and neat habit, its perfect hardiness, and the early period at which it blooms. Before the Snowdrops, Crocuses, and Aconites it gladdens us with its bright blossoms, and although its early blooms are sometimes covered some inches deep with snow, it does not seem in the least degree to suffer, for when the snow melts its blossoms come out as fresh as ever. As some people experience a difficulty in growing it, it may

be interesting if I give my own experience. I had for some years tried it in various parts of my garden, but with scant success, when an article in some gardening paper induced me to alter my mode of culture. I have a narrow border by the side of the drive up to my house which is somewhat overshadowed by trees and has a small shrubbery at the back, but nothing seemed to succeed in it, as it is very hot and dry, facing south. After reading the paper I thought that this seemed a likely place for the plant to succeed, so I took up a few of the bulbs that I had in other parts of the garden and planted them there. There was very little depth of soil, and I doubted very much whether the plan was likely to answer; however, it did so to perfection; the bulbs increased in size and seedlings sprang up all over the border. The seed vessels, as is well known, are in the form of a spiral twisted cord, and the seeds when ripe are shot out in various directions. In my case not only have the bulbs sprung up over the border, but the seeds have been carried into the shrubbery behind, and I am constantly digging up combs to give to my friends. I conclude, therefore, that a dry sunny border with a background of trees is what the bulbs really require; it may, of course, be that other growers have succeeded with it in places of a different character, but I only record my own experience.—H. B. D.

Escallonia scilloniense.—Unfortunately, the *Escallonias* are not really hardy in inland districts, a fact that is to be deplored, for they are usually free-growing shrubs, displaying a wealth of beautiful flowers and handsome deep green glossy evergreen leaves. Few shrubs have a more dense habit combined with freedom of growth. *E. macrantha* and its varieties are probably the best known and handsomest of the family, but an excellent companion is the rather new variety named above in which, though the general habit is similar to that of *E. macrantha*, the leafage is smaller and the flowers of an extremely delicate blush-white. Probably this is not in commerce, but flowers and sprays have been sent to us from Cornwall together with the information that the variety said to be a hybrid was obtained under the above name from the Scilly Isles and that it is a beautiful shrub, as one may imagine from the specimens sent. Where *Escallonias* will grow this should be grown. Other but little-known species are *E. montevidensis* (syn., *E. floribunda*) and *E. Philippiana*, both with white flowers and very attractive. *E. montevidensis* is rather difficult to propagate, and to strike cuttings one must lift a plant from the open ground and bring it under glass, encouraging the growth of weakly shoots, which may then be struck in gentle heat.—J. C. TALLACK.

WEATHER IN WEST HERTS.

A VERY cold and sunless week. The days were all cold, but the night temperatures in no way unusual. Indeed, on the coldest night the exposed thermometer showed only 9° of frost. The temperatures below ground have very gradually declined during the week, so that at the present time the reading at 2 feet deep is about 1° colder and at 1 foot deep about 3° colder than is seasonable. During the night of the 2nd inst. there occurred an exceptionally heavy fall of snow, which on the following morning covered the ground to the average depth of 10 inches. This is the deepest snowfall experienced here since January, 1887, or for thirteen years. When melted, the snow yielded nearly 1 inch of snow-water—equivalent to about 4 gallons on each square yard of surface—in my garden. At the time of writing the snow is still nearly 4 inches deep. A thermometer placed beneath the snow on the morning of the 3rd inst. has not varied 2° since it was placed there, the average temperature being about 1° below the freezing-point. During the last four days the atmosphere has remained very calm, and the direction of these light airs some point between north and north-east. The total record of sunshine for the whole week amounted to only a quarter of an hour.

E. M.
Beckhamsted, February 6.

WALL GARDENS. I.

I HAVE read with the greatest interest what is said in *Wood and Garden*, page 116, on the subject of wall cultures: "One of the best and simplest ways of growing rock plants is in a loose wall," &c.

Since my earliest youth I have had great admiration for old walls covered with plants. I remember when only ten years old my enthusiasm for the old retaining walls supporting the terraced vineyards in the Canton de Vaud near the Lake of Neuchâtel. These walls were then clothed with flowers and greenery, while the delicate fronds of *Cistopteris fragilis* and *Polypodium calcareum* formed a charming setting to the graceful bloom of *Corydalis*, *Campanula*, and *Linaria*. I say "were," for since those days the plasterers trowel has destroyed all this living beauty. Alas! what acts of vandalism are committed by orderly and practical people who think it their duty to repair and whitewash their walls at regular intervals! Unmindful of the picturesque, they sacrifice beauty to supposed utility, to the infinite regret of the artist and lover of Nature! How I loved these old plant-frequented walls, above all those of the old Château d'Yverdon, and the ancient ramparts of this little old Vaudois town! They might well be called a botanical sanctuary, for there alone, out of all Switzerland, was the one home of a rare *Hieracium*, *H. ligusticum*.

Alas, with the removal of the old ramparts this plant has disappeared, and for ever lost is also the pictorial *putina* which had gathered through the ages upon the castle walls. There have been works of demolition, of whitewashing and of putting-to-rights, and civilisation has done to death this graceful little Ligurian, whose pretty head was wont to dance to the northern winds.

Near Neuchâtel, in the walls that skirt the roads and footways and ridge the vine-clad hills, there lives and flourishes a rocky flora of the highest interest. The pretty Fern, *Ceterach officinarum*, spreads its thick crenated fronds around the rich tufts of the golden *Corydalis* (*C. lutea*) and the brilliant heads of *Hieracium lanatum*; but the mania for plastering goes on apace, and one after another the plants disappear.

On the shore of the blue Lake Lemán, at the foot of the vineyards of Lavaux, there are many great retaining-walls whose surface is almost hidden by flowers and foliage. Travelling by the railway-train that speeds along these shores, how often have I heard foreigners admire this sight, and ask how it was that this world of floral beauty could have been planted. Sometimes it is even difficult to persuade them to believe that nothing whatever has been planted, and that old Dame Nature herself has alone insisted on the placing of it all, in opposition to the will of man, who, on his part, vainly endeavours to struggle against her beneficent encroachment.

These walls, being kept continually cool by the moisture of the soil that they hold up, are the best possible receptacles for the rock-loving plants, whose whole effect presents a remarkable picture of plant beauty from May to September.

For there one sees, displayed against the grey stony background, and framed by the delicious greenery of trailing vine-branches, a whole scale of colour-tones, ranging from the clearest of whites to the most sombre of purples, and from purest blue to brightest yellow. And it is all hung about in a kind of pictorial haphazard on to the crest of the walling and into its minutest chinks and crevices: it hangs in wreaths and garlands,

seeming to pause at all the stony prominences; then springing one knows not how out of the very heart of the wall, spreading and flattening itself upon its surface, creeping downward and then clambering up—one knows not why—then, perhaps, laying hold of some other plant, when each will struggle almost fiercely in the fight to maintain its own dominion.

In one spot it will be the rosy *Saponaria*

cases of a blue that is nearly pure, and their lavish abundance ennobles the scene with a note of poetry. Then there are the Wall-flowers (*Cheiranthus Cheiri*), the ancient plant of the old castle walls, and one of the earliest that our ancestors brought into cultivation on their terraces, from whence centuries ago this sweetly-scented plant has been distributed. The Silver Basket (*Arabis albidá*), a plant of

A WALL IN THE JARDIN D'ACCLIMATATION, GENÈVE: VILLA SPINOSA, ERINUS HIRSUTUS, CAMPANULA MIRABILIS, SAXIFRAGA LONGIFOLIA, DIANTHUS NEGLECTUS, &c.

(Photographed by Miss Willmott.)

(*S. oeymoides*), whose large tufts spread into wide masses of bright carmine, that in some cases form the main mass of the vegetation. Close by are the bright yellow flowers of *Erysimum ocheolentum*, or those of the Golden Basket (*Alyssum saxatile*) escaped from some garden. Then come softer colourings—the rosy purple of *Erinus alpinus*, a plant of the high mountains that has come down from its native altitudes to bask in the warm sunlight of the Lake of Geneva. The *Veronicas* show a wealth of their fine lilac-blue bloom, in some

Caucasian origin that we have long had in cultivation, establishes itself on the crest of the wall, which it smothers with its myriad flowers of dazzling white. Here and there the Snapdragon (*Antirrhinum majus*) strikes a warmer note, with its spikes of bloom of crimson, or bright red, or orange-yellow. This, again, is a handsome foreigner escaped from gardens.

The blue Iris (*I. germanica*) is at home on the tops of walls, on terrace edges, and rocky eminences; its flowers, sceptre-like, are borne erect, and, with a queenly air, dominate the

plants around. It is the ancient Lily of the arms of France, the Fleur-de-llys of St. Louis and of the Royal House. It grows plentifully among the rocks, and it is a striking sight to see associated with its handsome blue-violet bloom the innumerable flowers of the yellow *Corydalis* (*C. lutea*), another southern plant that has made itself at home with us, and whose long season of bloom gives our walls so bright and lively a note of colour.

Several kinds of Pinks, and foremost the sweetly-scented *Dianthus plumarius*, often fully double (for the single-flowered type is rare in our gardens), have found a home in these old walls that border the wearisome iron road. The yellow-flowered Hawkweeds (*Hieracium*), the aromatic Thymes, Germander (*Tenacium Chamædris*), many kinds of Saxifrage, and, above all, the Stonecrops (*Sedum*) of various forms, the charming *Campanulas*, with their

blood. How wonderful and beautiful it all is! Then in cool and shady places and in northward facing slopes, the face of the wall is hidden by a thick clothing of Toadflax (*Linaria Cymbalaria*), whose long slender growths trail about in all directions, closely set with innumerable flowers like tiny Snaydragons of a modest and yet cheerful blue colour, whose effect is brightened by a spot of orange and white upon the upper lip. This is also a naturalised plant of southern origin. The bright and graceful frondage of a number of Ferns springs up on every side amid a setting of lovely Mosses.

And all this little world of green life, so varied in kind and shape, seems to be well and happily placed, though apparently nourished only by what it may borrow from the air and the weather, and from the dampness of the rock.

It is indeed a picture full of charm that, be-

the Great Artist sounding the glad note upon the mute instrument, and thereby pouring into the human heart the welcome flood of poetry!

How sad a sight would be the gloomy rock of Monaco were it not for the fragrant many-coloured plants that give it life! How dull would be the rocky Ligurian mountain walls if Lavender and Cistus, Hyssop and Fig Marigold were not there to flash out their resplendent flame and waft abroad their intoxicating perfume.

Geneva.

H. CORREVOX.

COLD WEATHER NOTES.

TEA ROSES AND WALLFLOWERS.

Frost has returned, not 22 of it, as I was assured there was three weeks ago, a fact about which, not having put out a registering thermometer myself, I feel some scepticism, still quite enough to need watching. The dwarf Tea Roses, both the younger and the older ones, are all safely tiled in under a comfortable quilt of earth up to their chins, and over that again bracken, tied into long bundles, and laid one on either side of the Roses, a plan that makes it cling closer and scatter less than when merely littered. I think they are safe, though the cutting winds of last week following the previous frost are trying, especially to the late comers. Every year I am astonished afresh at the hardiness of Tea Roses, hybrids, dwarfs and climbers alike. Examining some of the former on a mild day this week, I found that the little pink buds

leaf buds of course, not flower buds had grown perceptibly since I last looked at them, though anything less like Rose-growing weather than the interval had been could hardly be imagined. Up to the second week of December there were flowers to be picked on many. Dr. Grill and Princesse de Sagan being perhaps the kindest in that respect, if it is not discourteous to pick out where nearly all were kind.

Most of the beds in our little Dutch garden are now filled with dwarf Teas, overgrown in the usual way with *Saponarias*, *Sedums*, *Saxifrages*, and *Pansies*, and, for a winter garnish, *Wallflowers*, which, being pulled up in the spring, do the Roses, as far as I can observe, no harm. I wonder if most people grow those two genuinely unmistakable winter-flowering *Wallflowers*, Ear-

liest of All and Early Parisian? As a question of colour I myself prefer Blood-red or Harbinger, but the other two begin in October and go on till late March, and there is hardly a day during all that time but a fair handful cannot be gathered. Harbinger, despite its name, cannot be counted on here till the beginning of March. Blood-red and the most of the yellows are still later. At this moment we have four or five big vases filled with *Wallflowers*, and if gathered in bud and plunged deep they come out very well. If gathered after very hard frost has made their heads droop, they rarely, I think, recover; but a moderate amount of frost they seem to take little heed of, and two or three-year-old plants do quite as well as the younger ones, though too lanky and dishevelled to be of much use in beds.

Genuine winter flowers are so very near to all of our hearts, and the list of them is, alas! so exceedingly short, that it is a comfort to have something that one can absolutely depend on besides

CAMPANULA ISOPHYLLA ALBA IN A ROCK WALL.

dainty little blue bells, the yellow Rock Roses, so pleasant to see, the Knapweeds, the yellow Foxglove—all these abound, and mingle to the weaving of a strangely beautiful, many-coloured flowery carpet. But dominating the whole of this incomparable picture, by the importance of their colour-value, are the large vermilion panicles of the Red Valerian, or Jupiter's Beard (*Centranthus ruber*), another plant escaped from gardens, and whose home is in the south of Europe. A never-dying flame seems to play among its upright branches, while an intensity of vitality, a feast of colour, a busy movement of brilliancy pervade the bright bloom throughout its long flowering season; and while the heights above are whitening under the sheets of the fragrant Poet's *Narcissus*, as under a mantle of snow, a thousand feet below, along the blue lake shore, the rocks are as if red with

the time of the year what it may, ever presents itself in some new aspect and conveys some new impression of delight.

It is not only our walls of Lavaux that present these charming pictures, enriched as they are by some of the plants of important aspect, originally "escapes" from neighbouring gardens, but that have been established in them for centuries. Wherever these retaining walls occur we find them specially belovèd, and deserving of the close attention of the poet, the painter and the naturalist.

Along that wonderful coast that men call the Coast of Azure; along the luminous sunlit shores of the Mediterranean, the rock walls are the haunt of many a brilliant and dainty flower, sweet of scent and admirable in form. These bright living things grip hold of the dull, dead wall, endowing it with life and beauty; it is

Christmas Roses, Chimonanthus, Munstead Primroses, and the ever-faithful yellow Jasmine. Snowdrops, it is true, are just beginning to prick out (I gathered quite a large bunch yesterday). Winter Aconites are well above ground, and Scillas are promising to follow. Nevertheless, the frost fiend still hovers suddenly; the air has an edge cutting as spite or hate. By night the stars wink derisively, and winter is still at the very top of his strength.

EMILY LAWLESS.

Hazlatch, Gomshall.

WOODLAND AND FOREST.

TIMBER: A CROP THAT PAID.

I THINK it was the present honorary secretary of the R.S.A.S. that stated not long since that the difficulty hitherto in satisfying owners of land when advised to plant was that it had not been possible hitherto to point to examples of crops reaped and sold, and suppositions estimates were distrusted. That is, indeed, our difficulty at the present time. It is quite an easy matter to go into any wood and count and value the trees standing for what they are actually worth at current prices, but no wary advocate of planting would like to put forward a valuation of that kind as an encouragement to planters, because the honest figure is usually on the wrong side, and very seldom a correct record has been kept of previous thinnings. We know but few woods in which the standing crop would realise even a small margin of profit.

I have one example, however, to relate that I would like to give for what it is worth, and although I am not going to attempt to go through the orthodox process of comparing the value received for the crop with the original outlay invested at 4 per cent, I shall furnish planters with particulars that can be vouched for and which tell their own tale. Everything connected with the valuation and sale passed through my hands not long since, and the age of the wood I also know, the nature of the ground, and its value. I knew the owner of the land, who planted the wood just about sixty-five years ago from now. I knew the nurseryman who planted the trees, and I sold the crop for the planter's son, who is not yet an old man. The case is unique because the plantation was never thinned.

On one of the spurs of the Pennine range in Yorkshire, some 1300 feet above the sea and close to a famous grouse moor, the owner of a small farm had 40 acres of bad land on the higher portion of his ground. So poor was the soil that the tract was locally known as "Hunger Hills," the soil being thin, with here and there a tuft of Heather or wiry grass, and worthless for crops or pasture. Larch planting was then popular, and as the owner of the moors adjoining was planting extensively, the farmer resolved to plant his 40 acres also, and did so, putting the trees in about 4 feet apart. He divided the 40 acres into two lots of 20 acres each by a row of posts set up between them, and when he died he left one lot to each of his two sons, telling them, so the son told me, that each lot of 20 acres ought to be worth £1000 to them some day. One son sold his lot bit by bit at different times, but the other son kept his almost intact till the day it was sold for £950 nett, the money being paid in one cheque before the trees were felled. The present owner of the wood told me that he did not remember the trees being actually planted, but he remembered well going into the plantation to cut

whip stocks when the trees were about as high as himself, and when sold the plantation would be about sixty-three years of age, and I have known the plantation for half that period.

It is held by advocates of planting that the value of poor and waste lands may be raised by planting, and this is a case in point. The land before it was planted was so poor and exposed, that the owner could not have let it for pasture unless he had thrown some of his better land to it, and then, perhaps, it might have been worth perhaps 1s. per acre rent. The

be added to that, making the amount £1000. Omitting fractions, this comes to about £50 per acre for the sixty-three years, or 16s. per acre annually, while under the Larch, or thereabout, and the difference between 16s. and the rent of the land for agricultural purposes, before given, represents the increase in value by planting. I say nothing about rates and taxes or fences, as the former would have had to be paid in any case, and the fences were there before—one side belonging to the grouse moor and the other to the wood—dry walls, and only

PLANTS ON A WALL IN THE JARDIN ALPIN D'ACCLIMATATION, GENEVA: ANTIRRHINUM GLUTINOSUM, SAXIFRAGA LONGIFOLIA, AQUILEGIA JUCUNDA, ERINUS DIDISCTUS, &c.

present owner wanted to sell the land with the timber, and I tried to sell it for him, but neither the purchaser of the timber nor the adjoining owner thought it was worth the cost of conveyance, and it is still unsold. Now, taking this piece of land, 20 acres, worth about 20s. rent per annum, the total income from it for sixty-three years, the time it was occupied by the Larch, would have been £63. The Larch was sold for £950, and as the farmer had had all his fencing materials out of the plantation during part of the time, at least £50 may

have been chargeable to the latter. The crop of Larch I call a poor one, but that was due to the elevation, exposure, and poor soil. The largest tree in the wood contained 23 cubic feet, and the average was about 6 feet.

As to the cost of planting originally, I should say that it did not exceed £20, and that was the sole and only money ever spent on the plantation by either the planter or his son. This example has been extremely interesting to me, because the plantation was the only one I have ever known in this country that was

never thinned; the only one I was sure of the age of, and that was "clear cut" at the end and sold for a certain sum. I have stated the facts within the mark, and I would just like anyone to see the ground and situation where the trees grew—probably the worst that anybody would think of planting. The reason the wood was cut down was that the trees had reached maturity. They were becoming stunted, many were dying, and the annual increment was not equal in value to what the owner could secure by investing the price of the crop elsewhere, which was done, and now fetches him 6 per cent. in cottage property. I have suggested sowing the ground with Birch, and I have no doubt but that a crop equal in value to the Larch could be had in the same time.

When I say the trees were never thinned, I except the rails and poles taken out for fencing purposes now and then, but these were not many, and they were not removed on any thinning principle, but just from here and there—perhaps the worst or dead trees. When the lot was sold the wood resembled a continental Pine forest very much, the trees being of very unequal girth but tall and clean. The wood was about four miles from a station and the timber not easily got away, or the price given would have been higher.

One instructive fact that I have drawn attention to before in your pages I must mention. A gully or ravine ran through the wood, and here the main value was found, as the trees were taller, averaging about 12½ cubic feet each, while at the margin on the most exposed side the average was much less than half that figure and the annual rings thread-like by comparison.

J. SIMPSON.

ORCHIDS.

LYCASTE SKINNERII.

THE Rev. Francis D. Horner, of Greta House, Burton-in-Lonsdale, sends me to-day the finest bloom I ever saw of the pure white form of *L. Skinnerii*. He says that it was bought as *L. Skinnerii alba gigantea*.

Not only are the blooms of the very largest size, but the sepals and petals are also broad, well formed, and of great substance. The flower measured 6 inches across, while the white is very pure. The pure white form is always greatly valued by Orchid fanciers, and there are many varieties of this form of various degrees of excellence, but there must be one best of all, and I fancy it is in the Greta House collection.

Messrs. J. Veitch & Sons in their excellent "Manual of Orchidaceous Plants" observe, under the heading of *Lycaste*, that "*L. Skinnerii* is one of the easiest Orchids to cultivate, requiring only a temperature that does not sink below 40° C. (50° Fahr.)." Like a good many Orchids, it is very easily grown for half a dozen years or so after being imported, but the latent vitality stored up in the native pseudo-bulbs seems gradually to decline after a time, although there are many instances of cultivators succeeding in prolonging the vigour of the plants for a considerable number of years.

The infinite variety of colour and form to be found in this handsome species of *Lycaste* is admirable. Besides the pure white varieties there are others nearly white. A very distinct form is *L. armeniana*; it has a tinge of yellow in the sepals and the lip, the petals being white. Others have the petals and sepals white, with a pink or rose flush. Many have rose and rose-carmine sepals and petals, with a

crimson-maroon lip. Numerous names are given in the various works dealing with this Orchid since the large batch of plants was sent over from Guatemala by Mr. George Ure-Skimmer in 1841, but probably few of them are now in existence, all that is left of them being a pleasant memory.

One of the most successful cultivators of *Lycaste Skinnerii* some twenty years ago was Mr. Henry Little, of Baronsholt, The Barons, Twickenham. He used to exhibit splendid specimens with a score of flowers or more on each of them. Mr. Little is still a keen cultivator of orchidaceous plants, and could reveal something of the details of culture of this fine plant. One gardener used to grow it well in a mixture of leaf-mould and fibrous peat, the plants being placed at the cool end of a *Cattleya* house. This, I believe, is the best position for them, as they do not like a high temperature, but the cool house does not seem to answer in winter, although they would do well there during the summer and early autumn. I grow the plants at the cool end of the *Cattleya* house, where the temperature would be from 50 to 55 as a minimum in winter. Keep the leaves clean by sponging occasionally, and do not over-rest the plants in the resting period. The bulbs ought not to shrink from lack of moisture. In the growing season the supply of water should be liberal. The flowers last a long time in good condition, but, like all Orchids the sepals and petals of which are of a fleshy nature, they are apt to become marked with decay spots in a low temperature and a damp-laden atmosphere.

A very handsome variety is figured in the *Botanical Magazine*, t. 1445, which is thus described: "Sepals white, tinged blush; petals white, more tinged with blush than the sepals." Mr. Bateman described it as early as 1810 under the name of *Maxillaria Skinnerii* in the "Botanical Register," mis. 101. He says: "This is the finest *Maxillaria* I ever saw. It has a gentle odour, but the lip is magnificently purple white, with centre figured in deep rose colour. Flowers in December and January, and even in April have I seen it." The flower he describes was 1½ inches across. The formation of the flowers of *L. Skinnerii*, their infinite variety of colour, and their substantial and rounded form place them nearer to florists' flowers than any other Orchids known to me. Mr. Horner, referring to his best white variety, says: "I never saw such an upstanding, bold, and shapely form—quite a florist's type. It has huge bulbs and shapely foliage; the leading blooms were larger than the one sent." At Lowfields, as at Greta House, Mr. Horner has proved himself as great an adept at cultivating Orchids as Tulips and Auriculas. His greatest feat at Lowfields was obtaining a lot of worn-out plants of *Cattleya citrina*, and restoring them under his careful management into their pristine vigour.

The culture of Orchids must be a labour of love; they cannot thrive under the care of a gardener who is not deeply interested in them, as they require careful watching morning, noon, and night; but this applies to all classes of plants, from Pumpkins to Pine-apples and from Sedums to Orchids. The enthusiast succeeds.

J. DOUGLAS.

CYPRIPEDIUMS.

SEASONABLE NOTES.

THE winter-flowering section of species and hybrids that have recently passed out of flower may be examined to ascertain the condition of the potting compost, and where necessary

REPOTTING.

may be proceeded with. The kinds that have

recently passed out of flower include such well-known species as *C. venustum*, *C. callosum*, and the many varied and beautiful forms of the montanum section of *C. insigne*. The older known, or salyense form, which flowers later and is still in perfection, should not be disturbed until the flowers are removed. Such hybrids as have been derived from the intercrossing of the above species, and the *C. Spicerianum* hybrids, which include *C. Leeanum*, *C. Ceres*, *C. Hera*, *C. Allamianum*, and numerous other varieties, may also be included. A plant should not be repotted unless the compost has become sour and decayed or the plants have become too large for the pot. Where the soil has got into bad condition, turn the plants out of the pots, carefully removing all the decomposing material, and cut away all decayed matter. Wash the roots by dipping them in a pail of warm water, thus cleansing them from decayed matter. In cases where the plants have outgrown the pots and the roots have become matted and adhere to the sides of the pots, break the pots, and so liberate the imprisoned roots. It is difficult to attempt to turn plants out of the pots when in this condition without injury to the roots. Breaking the pot, therefore, is the only means by which this may be avoided. In repotting, the pots used should be sufficiently large to contain the plants comfortably. These should be cleaned and drained to two-thirds their depth with clean broken potsherds. Then place the plant in position, and work in a few more crocks about the roots, and fill up the remaining portion with the potting compost, making the whole moderately firm about the base of the plants.

THE POTTING COMPOST.

The material required for the neighbourhood of London and in smoky districts should consist of good fibrous peat and living *Sphagnum Moss*, two parts of the former to one of the latter. To this may be added a liberal sprinkling of rough sand or finely-broken crocks. In brighter and more favourable atmospheric conditions, a liberal portion of good fibrous loam may be added with advantage for such species as *C. insigne* and its allied sections of the green-foliaged varieties. Unless the surrounding conditions are favourable, it is not advisable to include loam.

TO INCREASE THE STOCK.

With regard to rare and valuable plants, it is not always an advantage to rely on a single specimen longer than is absolutely necessary. *Cypripediums*, like other plants, are prone to disease and death. It is, therefore, advisable to procure a second plant as early as possible. Large plants are more difficult to accommodate than smaller ones, and they are not generally so useful when required for decoration. In the case of special varieties, a plant may be divided that has three successive growths on a rhizome, making the division intermediate between the second and third growth back by cutting the rhizome asunder. The best time to effect this is when the new roots are being emitted from the base of the last or newly-made growth. When in this condition they quickly get hold of the new material and become re-established. After the rhizome has been cut, remove the portion desired with as much root and as little injury as possible, and without disturbing the back growth, but fill in any space made with potting compost, and in due time new growth will appear. The breaking up of large specimens is best done at the potting season and the divisions potted up in the usual way. Repotted plants should be thoroughly watered, using rain water, administered through a moderately coarse rose on the water-can.

H. J. CHAPMAN.

ORIGIN & HISTORY OF SOME OLD GARDEN FLOWERS.

LARKSPURS (*Delphinium Consolida*, L., and *D. Ajacis*, the Rocket Larkspur) have been grown about 300 years in England; but only the former is wild, being common in cornfields about Cambridge, and in Sussex, near Steyning, in 1800. White, pink and blue-flowered varieties abounded. *Consolida* was the name given to

certain plants, including our two Daisies and the Comfrey, in the Middle Ages, as "consolidating" broken bones; but the word was not applied to the Larkspur until the 16th century. Ajacis is derived from Ai Ai, as these letters are said to be stamped on the petals. The story runs that Hyacinthus, a Spartan youth, was accidentally killed by a quoit; from his blood sprang the flower marked with the exclamation Ai! Ai!

ACONITE (*Aconitum Napellus*, L.) is pretty freely distributed over Europe and a native of England in a few counties. As a cultivated plant it appears to have been introduced in the 16th century, when it was called *Napellus serotinus* or *Aconitum flore cœruleo*. This is our most deadly poisonous plant, and many families have been the victims; since it has long been a favourite in cottage gardens, whence the root has been eaten for Horse-radish. *Napellus* is the diminutive of *Napus*, as the root resembles that of the Rape.

PEONY (*Pœonia officinalis*, L.)—This is the source of the common and numerous single and double sorts. It is a native of Southern Europe, and grows in rocky places in Italy, &c. Those varieties with broader leaves and larger flowers were called "male," and others of a more starved condition with smaller flowers and narrower leaf-segments were considered "female." The Peony was used in medicine in the 14th century. A variety called *P. corallina* was established on the island "Steep-holmes," and regarded as introduced; but since several Mediterranean plants found their way to Normandy, thence to the Channel Islands, and to the south-west of England and south-east of Ireland, the Peony might well be one of that little flock.

POPPY (*Papaver somniferum*, L.)—The Opium Poppy is with but little doubt the cultivated form of *P. setigerum* of South European cornfields. A medicinal plant through the Middle Ages, it might have been introduced by the Romans, to whom it and opium were well known. The juice of the Poppy, Hemlock, Bryony, Lettuce and Henbane mixed with vinegar was an anæsthetic drug called "dwale," for surgical operations; after which, the patient was awakened by rubbing his temples with salt and vinegar. It is the "Gall" of Scripture.

SCARLET POPPY (*Papaver Rhœas*, L.)—This was cultivated in Pliny's time. Varieties of various shades as well as double ones have probably been long in cultivation, but we owe it to the skill of the Rev. W. Wilks to have established the new race of Shirley Poppies, raised from one flower in which the red petals were slightly margined with white. From this, by selection, all the numerous existing sorts were derived. An other step was to eliminate the black anthers. This was done and the race established.

CLOVE PINK (*Dianthus Caryophyllus*, L.) is a native of the Mediterranean region, and illustrates the wonderful varieties of form and colour produced by various soils, &c., under cultivation. It was formerly called Gilloflower, a corruption of *Caryophyllus*. It is occasionally found wild on old walls like the Wallflower, and, therefore, was probably grown in monastery gardens of the Middle Ages, as many varieties existed in the 16th century. An interesting hint at a possible cross-fertilisation in Nature occurs in "The Winter's Tale," where it is said of streaked Gilloflowers, "Some call Nature's bastards." So, too, Shakespeare speaks of "pale Primroses that die unmarried."

THE CABBAGE AND PROVENCE ROSES (*Rosa centifolia*). This is the Rose of the classics and the source of attar or oil of Roses. It appears to have been brought from the East at

FRAME COVERED.

an early period, and has been long cultivated in Europe. Lindley says it is indigenous in the eastern parts of the Caucasus. The Greek writers from Homer downwards speak of it. Herodotus writes of the Roses of the garden of Midas having more than sixty petals. The same Rose probably was grown in the *Rosaria* of Pæstum.

ASPHODEL (*Asphodelus ramosus*, L.)—This was called by Turner (A.D. 1548) *Albuscus*, *Hastula regia* or *Duche Affodil*; it was known in the 11th century as "clausing gresse." The word "Affodil" gave rise to *d'Affodil*, but it is not clear why the latter name became applied to the *Narcissus*. Prof. Skeat says, "perhaps derived from the French, *Fleur d'Affrodille*." Since the name is derived from the Latin, it, perhaps, was introduced by the Romans. Quantities grow on rocky hilly ground in Malta.

WHITE LILY (*Lilium candidum*, L.)—Well known to the ancients, and cultivated in gardens in Egypt and Persia, &c., the names *Shushan* and *Susan* meaning Lily. It appears to have

FRAME WITHOUT COVER

been a native of South Europe, but probably exterminated from fields to be grown in gardens. This was the case in Malta, where it is now occasionally found by peasants' houses. It was called *Argentea*, *Argentea* or *Lilie* in a list of plants of the 13th century. Post records it as still growing wild on Mount Lebanon.

G. HENSLOW.

COOPS FOR WINTER PROTECTION.

PERHAPS the most useful flower in the hardy plant garden at this season is the Christmas Rose. We have a place at Wisley which suits both the Winter and Lent Hellebores. We got our supply from Mr. Ware, of Bath, who had a good strain and some good varieties. Ours are planted in a bank at the side of a ditch facing north, shaded by a high hedge at the south side of the ditch. The soil is light loam, and in ordinary years rather moist. Some good authorities advocate planting in full sun; our experiments have gone the other way. Perhaps it is a question of stiffness of soil. As the flowers when out have often hard frosts and heavy rain to contend with, glazed lights are frequently recommended to protect them. My object in this note is to recommend coops, as being much lighter and as covering larger plants. We began by using common wicker hen-coops covered with green scrim, but after a time the wood got out of shape and decayed, so iron wire was substituted for the skeleton. If these coops are put by in the summer, if not in use, in a dry place, they will last for many years. After the Hellebores are over they are useful for *Anemone fulgens*.

GEORGE F. WILSON.

Heathcote, Weybridge Heath.

Erica barbata.—Though less showy than many of the more popular Heaths, this species is very pretty, and merits notice from the fact that its flowering period extends throughout the winter months. It forms a dense growing specimen with tiny leaves, while the little white blossoms are borne in great profusion. The individual flowers retain their freshness a considerable time, and a succession is kept up from the same shoot or cluster. The entire plant is more or less hairy. This species was introduced a century ago, but it is rarely seen, though during the present winter I have met with it in good condition in two or three nurseries where hard-wooded plants are still grown. H. P.

Rubus biflorus.—The great beauty of many deciduous trees and shrubs during the winter months has been referred to in recent numbers of THE GARDEN, the white-stemmed Brambles among the number coming in for their share of recognition. During a recent visit to Kew I thought the brightest outdoor feature of a dull winter's day was furnished by the clump of *Rubus biflorus* near the flagstaff, their peculiarly whitened stems causing them to stand out conspicuously from the sombre surroundings. The plants at Kew have the old wood cut out freely, and this is undoubtedly the way to treat this Bramble, as young vigorous shoots are most effective in their colouring. It has been grown at Kew for many years, but is not easily obtainable from nurseries. There are several species with the stems more or less whitened, but this is the best. Though the popular name Bramble does not suggest choice subjects of high ornamental value, yet there are many such in the genus *Rubus*. Besides this we have the nearly allied *R. leucodermis*, with bluish white stems; the Rocky Mountain *R. deliciosus*, whose pure white blossoms, like single Roses, are so freely borne in spring; and the double pink Bramble that flowers in such profusion, even in hot sandy soils, during July. To these must be added the cut-leaved Bramble and that curious antipodean species, *R. australis*, which forms a tangled mass of wiry stems and midribs, the blade of the leaf being almost, if not quite, suppressed. This is plentifully furnished with small, but sharp hooked spines. T

AN ARTIST'S NOTE-BOOK.

IRIS ALATA.

THIS is a charming winter-flowering Iris of the bulbous group, and in mild winters is in bloom long before January. These winter Irises, however, deserve protection against the weather. Storms of rain destroy their beauty, soil splashes over the petals and spoils their delicate colouring, and for this reason when a little colony is in bloom on some sunny border or in a nook in the rock garden, a hand-glass should be placed over it for protection. I have a delightful panful of this Iris in flower in a cold frame; it is interesting to see the variety of colours, one flower as white almost as a snowdrift, others shaded with blue, some deep, others pale, delicate tints melting into each other, relieved with spots and splashes of rich yellow. The foliage is so much like that of the Leek in colour and form that Iris alata is sometimes called the Leek Iris; it is, perhaps, the most distinct in growth of the entire race. It flowers readily in a warm border of light soil, and plant the bulbs in a carpet of mossy Saxifrage, Stonecrop, *Hemiparia*, or similar low-growing plant to protect the flowers from soil splashes. T. E.

THE TREE WYCH
HAZEL.

(HAMAMELIS ARBOREA.)

THE next illustration shows a flowering shoot of the Tree Wych or Witch Hazel (*Hamamelis arborea*), the brightest flowering shrub of winter, and rarely disappoints. Year after year the tree will bear its golden burden of blossom, a quaint twisted, starry kind of flower of golden yellow, softened by its crimson calyx setting. The shoot represented was kindly sent to Mr. Moon by Messrs. J. Veitch and Sons, who showed a small tree in full flower at the last meeting of the Royal Horticultural Society. Even in the murky light of the Drill Hall its golden flowers thickly placed on the leafless shoots made a bright patch of colour, undimmed by the more flaunting beauty of the Orchids heard by. The Tree Wych Hazel has been often written of, so much so that it is hardly necessary to refer to its hardiness and vigour. But it is a rare shrub still, though venturing to gild January with gold and open its flowers in the winter sunshine ere the Snowdrop has dared to brave snow and rain and searching wind. The way to realise the quiet beauty of the *Hamamelis* is to group it. A group of six small trees will make some effect, and as we saw once, we believe, in the Royal Gardens, Kew, the surface of the bed may be covered with the little tufted

crimson-berried *Gaultheria procumbens*. Before planting the group remember the Wych Hazel flowers in winter; it delights in sunshine, shelter without shade, a good well-drained soil, and to be left alone. There are other species of *Hamamelis*, viz., *H. japonica*, its variety *Zuccarimiana*, and *H. virginica*, but *arborea* is the most beautiful and the most satisfactory in all ways.

THE INDOOR GARDEN.

GLOXINIAS.

GLOXINIAS are the most beautiful of all indoor flowering plants, and when grown under favourable conditions they may be used for house decoration or as window plants. They are often grown in a much higher temperature than is necessary, with the result that both foliage and flowers are too tender to be removed from where they are grown without suffering. When grown

under cool treatment and well exposed to the light they make thick fleshy leaves and flowers of good substance, with short, sturdy flower-stalks. For early flowering the dormant corms should now be started without delay. Seeds may also be sown, and with good treatment will make good flowering plants the same season, and will come in well to succeed those grown from corms. It is important that the compost used for sowing the seeds in should be as free from weed seeds as possible, also that it does not contain anything likely to favour fungoid germs. In sowing the seed it is better to err on the side of sowing too thinly than otherwise. The seed pots should be placed where they get as much light as possible without the direct rays of the sun coming on them. A piece of glass may be laid over the pots, but no shading. If the soil is well moistened when the seed is sown, no more surface water will be required, but if there is any appearance of dryness, the pots may be dipped, but not soaked or plunged deep enough for the water to flow over the rim of the pot.

The glass should be removed for a short time every morning, and as soon as the seeds begin to germinate it may be taken away altogether. Few subjects require more care, and a little neglect may prove fatal to the young seedlings. They may be pricked off as soon as they can be handled and potted singly as soon as they are well established. From the start onwards they should have all the light possible, and will require little or no shading until they are in flower, when a little shading will ensure the flowers lasting longer. In starting the corms they may be placed on any moist material and remain until they begin to start growing, when they may be potted. *Gloxinias* will grow in almost any ordinary compost. I prefer good fibrous loam enriched with stable manure, or if the loam is heavy, leaf-mould and peat may be added. Good drainage should be given, and in potting, the soil should be pressed only moderately firm. After potting, the best position will be on a shelf close to the glass, and very little water should be given until they have made a good start.

After the buds begin to form, manure may be used freely, but if any of the artificial fertilisers are applied, care should be taken not to put them on the leaf stalks. In the earlier stages a little extra warmth may be beneficial, and if well exposed to the light they will keep short and sturdy. It is after they are well advanced that the cool treatment is so beneficial. Such good varieties may now be had from seedlings, that it is quite unnecessary to trouble about named sorts. One-year-old corms make the best plants, and by raising seedlings annually the best can be selected for the following season; and it will be found that these are not so liable to disease or insect pests as old corms, or those propagated from the old named varieties.

By raising seedlings annually a selection of the best can be made for early flowering the following season, and a number of plants may be grown without taking up much space when only required for selecting the best types. For this purpose planting out in a frame on a spent hotbed may be recommended. A. HEMSLEY.

CARNATIONS IN POTS.

THERE is a way of growing Carnations in pots differing in some respects from that followed by florists, and, as I think, better suited to the wants of the many gardeners and amateurs, who are by no means particular whether a petal is rose-leaved or saddle-backed provided the flower of which it forms a part is possessed of good all-round qualities. The system, too, is spreading, as I noticed in a few gardens last year plants grown on this simple principle.

My own method of culture is something as follows, though the Carnation is so accommodating a plant, provided it is subjected to no coddling treatment, that less care than that recommended

IRIS ALATA AND THE WHITE VARIETY.
(From a drawing by H. G. Moon.)

may produce results equally satisfactory:—Strong layers, well rooted, are selected in September, as early in the month as possible, and are potted into 4-inch or 5-inch pots, and when they progress in a favourable manner, require repotting into larger ones towards the end of October. If, however, the season is adverse and a shift uncalled for in autumn, then they are repotted as early as convenient in February. A 7-inch pot is sufficiently large for a strong-growing variety, and a 6-inch for the less robust, a smaller size than that invariably yielding less good results. An important period in the life of the plants is that which comprises the three months of winter, during which time the application of water is all but stayed, and the pit in which the plants are preserved kept cool and perfectly dry. Under these conditions it might be supposed that the plants would remain in an absolutely dormant condition. As a fact, however, there is a slow and, as the weeks pass, a perceptible thickening of the stem which does not terminate till the return of spring starts the growth, when the value of this period of enforced rest becomes apparent in the increase of the number of flower-stems that are produced. In some instances flowers are produced so profusely, that it is difficult to secure stock. One variety, still standing in its pot in the state it was set aside after flowering in order to provide stock in spring, had, I notice, no less than thirteen flowering stems and only one shoot to layer. Dryness also contributes largely to the diminution of "spot" contracted in damp autumns.

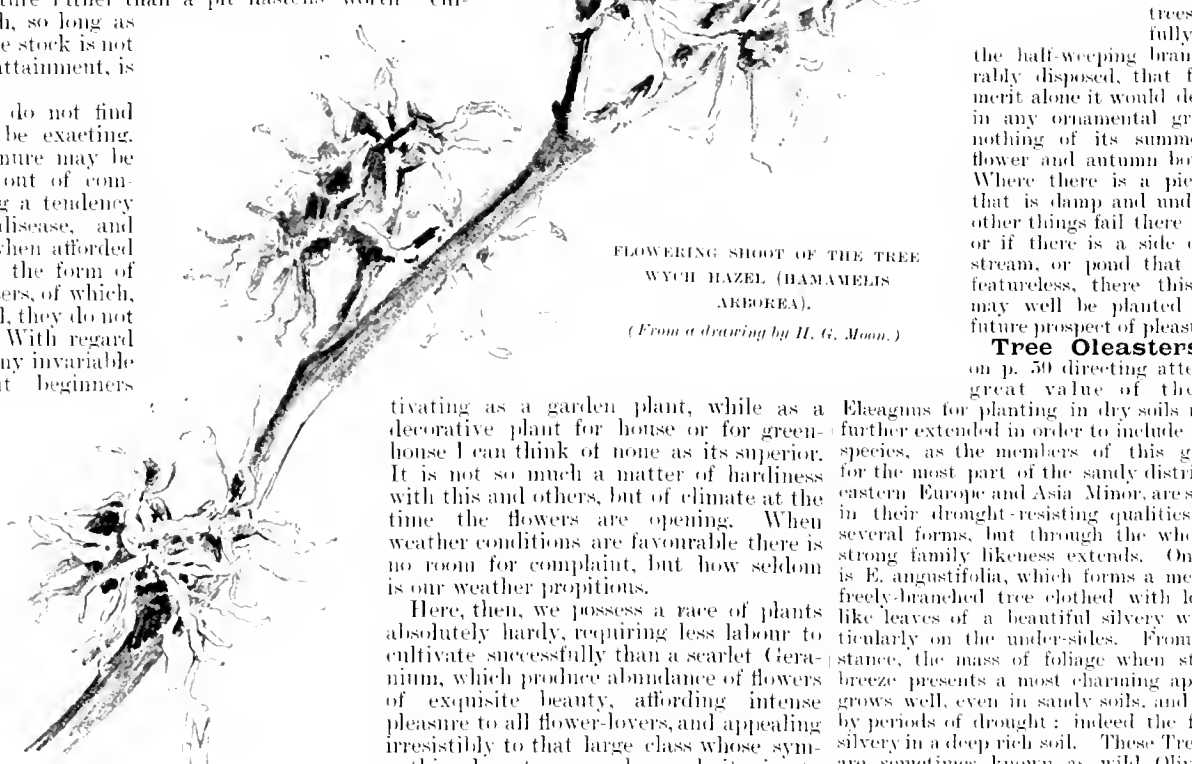

To ensure an early summer bloom, it is of course essential that the plants be grown entirely under glass, and in my experience a large airy structure rather than a pit hastens flowering, which, so long as the health of the stock is not lowered in its attainment, is most desirable.

As to soil, I do not find Carnations to be exacting. As a rule, manure may be altogether left out of composts, as having a tendency to engender disease, and manurial aids when afforded applied only in the form of artificial fertilisers, of which, it may be added, they do not require much. With regard to water, it is my invariable experience that beginners err in over-watering, especially early in the season, when careful watering is of paramount importance.

A judicious thinning of buds is decidedly helpful in not only increasing the size of those left to expand, but also in improving the colour of the blooms. Also for these reasons the plants require shading from hot sun while the flowers are opening as well as afterwards. It is impossible to secure delicate and refined colouring of such sorts as Persens, Zingari, and Brodrick, as well as of the soft peachy shades occurring

in kinds of which Seagull may serve as a type, in any other way. A thick shading material exerts, too, a pronounced influence in lowering the temperature, or rather in preventing the temperature from increasing to a degree prejudicial to good colour. One notices in the deeper colouring of Malmaisons at this time of year, when not excited by fire-heat, the value of a low temperature as a deepener of colour in Carnations.

All kinds of Carnations are amenable to pot culture, and the sorts to be preferred are undoubtedly those possessed of a floriferous and upright habit of growth, of which Hampton, Germania, and Mephisto may be named as notable examples. These require the minimum of support, and when in good condition and full of bloom are invaluable for decorative purposes. But, apart from sorts that may very well find a place in the summer pleasure garden, there are dozens of lovely varieties that it would hardly be wise to flower in the open which by their beauty well repay the little trouble incident to their cultivation as greenhouse plants. Of all Carnations, the one that is the most attractive to most people is Hidalgo, distributed this season for the first time. I shall be greatly mistaken if this variety will ever be worth en-

FLOWERING SHOOT OF THE TREE
WYCH HAZEL (*HAMAMELIS*
ARBOREA).
(From a drawing by H. G. Moon.)

tivating as a garden plant, while as a decorative plant for house or for greenhouse I can think of none as its superior. It is not so much a matter of hardiness with this and others, but of climate at the time the flowers are opening. When weather conditions are favourable there is no room for complaint, but how seldom is our weather propitious.

Here, then, we possess a race of plants absolutely hardy, requiring less labour to cultivate successfully than a scarlet Geranium, which produce abundance of flowers of exquisite beauty, affording intense pleasure to all flower-lovers, and appealing irresistibly to that large class whose sympathies do not run so deep. Is it wise to neglect them?

It is unfortunate that the rigid rules that bind florists have debarred visitors to shows, such as that at the Crystal Palace, from seeing the Carnation at its best as a pot plant, but we might as well condemn the Chrysanthemum—because, cultivated for show purposes, it is unsightly—as the Carnation, because its appearance is so devoid of decorative effect. R. PACE.

The Quince.

The *Gardener's Chronicle* of Jan. 27 has an extremely pleasant and highly instructive article on the Quince. It makes one think how undeservedly this beautiful small tree, with its graceful habit of growth, charming flower, and handsome and useful fruit, is neglected. Few small trees are more beautiful in winter than the older kind of Quince, with the smooth, roundish fruits; the little trees are so gracefully poised, and

the half-weeping branches so admirably disposed, that for its winter merit alone it would deserve a place in any ornamental ground, to say nothing of its summer beauty of flower and autumn bounty of fruit. Where there is a piece of ground that is damp and undrained, where other things fail there it will thrive, or if there is a side of a ditch, or stream, or pond that is blank and featureless, there this pretty tree may well be planted with a sure future prospect of pleasure and profit.

Tree Oleasters. The note on p. 50 directing attention to the great value of the evergreen

Elaeagnus for planting in dry soils might be still further extended in order to include the deciduous species, as the members of this group, natives for the most part of the sandy districts of South-eastern Europe and Asia Minor, are second to none in their drought-resisting qualities. There are several forms, but through the whole of them a strong family likeness extends. One of the best is *E. angustifolia*, which forms a medium-growing freely-branched tree clothed with long, Willow-like leaves of a beautiful silvery whiteness, particularly on the under-sides. From this circumstance, the mass of foliage when stirred by the breeze presents a most charming appearance. It grows well, even in sandy soils, and is unaffected by periods of drought; indeed the foliage is less silvery in a deep rich soil. These Tree *Elaeagnuses* are sometimes known as wild Olives, from the general aspect of the tree as well as the fact that their fruits are something like those of the Olive; and being rich in saccharine matter they are sold in the markets of Constantinople. According to London, *E. hortensis*, of which he considers *E. angustifolia* a variety, was introduced in 1633. In the Kew Hand-list *E. angustifolia* is assigned specific rank. The Oleasters should be far more grown and not confined to a few gardens. I hope they will be more planted.—T.

GARDENING OF THE WEEK.

KITCHEN GARDEN.

EARLY PEAS ON SOUTH BORDERS.

WHEN the soil is sufficiently dry and in a workable condition in the warmer parts of the kingdom, it is well to sow some early dwarf Peas, as though growth will be slow at the start, this sowing, if made on a warm border, will turn in at the end of May or early in June. Such kinds as germinate freely are best, and in heavy soils Marrows are not so suitable for early sowing, but there need be no fear if such varieties as Chelsea Gem, Bonitiful or Daisy are sown; the two first-named are the earliest, but the latter crops well. In unsuitable land it well repays the cultivator to assist germination by adding such materials the soil needs, as in wet or badly-drained land by using soils that lighten there is a considerable gain in earliness. As regards sowing the seeds, sow thicker than some weeks later; on the other hand, there is no gain whatever in sowing Peas like Mustard and Cress, each plant robbing the other, and in the end all being too weak to crop freely. In a measure the same success that has been obtained of late years with the Sweet Peas, by giving more room and better cultivation, applies equally here, as with ample room to develop there are fewer enemies to contend with, the haulm being so much better able to ward off attacks. In the northern parts of the country it may be well to defer sowing for a fortnight, but the same advice holds good as regards varieties and soil.

EARLY LEEKS.

Of late years Leeks have become more popular, and they are deserving of good cultivation, as, being of a milder flavour than the Onion, are more enjoyed by many persons. A few words will describe their cultivation for early supplies. I am not a great lover of this vegetable as grown for exhibition—I mean roots nearly 1 yard long and much labour spent on their production. On the other hand, the thick roots with stems sufficiently blanched for cooking without much cutting up are more useful. Now is a good time to sow seed for autumn supplies, and in cold or exposed gardens I would also advise sowing under glass, such as in cold frames, for the main crop, as if the sashes can be removed later a much stronger plant is secured. Glass not being available, a box of seed will produce a quantity of seedlings if the latter are pricked out when large enough and finally planted out in June in good soil. Leeks are more valuable in severe winters than many other vegetables, as they are very hardy and will keep sound well into April; indeed the Musselburgh keeps good much later. For early supplies I find the Lyon one of the best, and its compact habit is advantageous for general use. The reason I advise sowing Leeks under glass (heat is not necessary) is to gain time, as the seed sown in the open in the spring is a considerable time germinating. G. WYTHES.

INDOOR GARDEN.

FORCING PLANTS.

ALL kinds of forcing plants will come away freely now if introduced into a genial temperature and humid atmosphere kept right by frequent syringings. Spiræas, Azaleas, Lilacs, Deutzias, Guelder Roses, Staphyleas, Lily of the Valley, and bulbs of all kinds must be brought on in batches equal to the demand. Lily of the Valley (natural crowns) enjoys a strong bottom-heat and frequent supplies of tepid water. To lengthen the spikes the plunged pots should be covered with a box in which they can be kept dark, and remain so until the lower bells begin to open, after which they must be gradually inured to the light, and finally removed to a lower temperature. The same thing applies (except as to the free supply of water) to all bulbous plants, except Narcissi, in the early stages if great length of stem is a desideratum. Lilacs, too, if wanted white must be forced in the dark, and for these a warm Mushroom house—too

warm, by-the-by, for good Mushroom growing will suit. Successional batches of all the above may be brought into Peach houses, Fig houses, or any other such place at work. Here they will come on more naturally than in the higher temperature of the forcing house and the flowers will last better.

LILIUM HARRISII.

Forward batches of this Lily showing roots round the base of the stems should be top-dressed at once with good rich soil. Later batches may be brought on as required, and I find that they do well in the same house with the Arums, and as they also are susceptible to constant attacks from aphides, the frequent vaporisings are of benefit to both.

ROSES.

Hybrid Perpetual Roses which have been prepared for forcing and pruned a week or two back will, if brought into a suitable house and gently forced, give nice flowers about the middle of April; and Peas, which are more quickly responsive to heat, will be earlier still. A nice gentle hotbed of leaves and manure is a great help in Rose forcing, and this should be built high enough to bring the plants as nearly as possible up to the glass, which should be clean. Stand the plants on the bed without plunging them. Damp down the stages and floor occasionally and keep the surface of the bed moist by syringing, but do not syringe overhead for the present. A night temperature not exceeding 50° will be sufficient for the present, and the house may be kept closed, or nearly so, except on warm and mild days, for draught is a great danger to Roses, bringing mildew in its train.

SHOW PŒLARGONIUMS.

It is rather late now to advise the final potting of these plants, as this should have been done in December, but there is still time for the plants to make roots before flowering, and it is better to pot them on than to leave them in the small pots to which they were reduced after being cut back. Pot firmly in good fibrous loam, adding about one-sixth each of sand and well-seasoned horse droppings. Avoid leaf-mould, as this frequently produces spot in the leaves and general ill-health. After potting, stand the plants in a light position in a cool, airy house, and water charily until the roots are running freely in the new soil.

J. C. TALLACK.

Livermere Park, Burg St. Edmunds.

CHRYSANTHEMUMS.

ASSUMING all has gone well with the cuttings under propagation, these will now have become rooted and will require to be quickly transferred into 3½-inch pots, as a check at this period means a serious misfortune.

The pots and crocks should be thoroughly washed and allowed to become perfectly dry before using. Good drainage is of vital importance in all stages of their growth, and this cannot be too much impressed on the beginner, for unless the water given can pass away freely, owing to imperfect drainage the soil quickly becomes sour, and instead of the plants presenting a robust and healthy appearance, small sickly leaves and growth will be the result.

One large crock covering three parts of the bottom of the pot should be placed over the hole, the hollow side downwards, and gradually building these up to the required height, in various sizes of course, placing the larger at the bottom with a layer of quite fine ones, free from dust, on the top. On this should be placed a small quantity of tough fibre taken from the loam heap, carefully sifting out every particle of soil with a ½-inch mesh sieve, and taking care that no worms are allowed to find a home in the compost. The drainage should be as perfect when turned out for the next potting as the day it was placed therein.

The compost for this potting should consist of three parts good fibrous loam broken up finely, one part well decayed leaf-soil, one part old spent Mushroom-bed manure, both of which should be passed through a ½-inch mesh sieve, a liberal supply of coarse silver sand and a small quantity of finely

broken charcoal and bone-meal. The whole should be thoroughly well mixed together and used in a moderately dry condition, so that when potting it can be made firm.

The most suitable place for a time after this potting is a heated pit, where just sufficient heat can be turned on to counteract frost. Arrange as near the glass as possible on a bed of finely sifted coal ashes, do not water for about three days, but damp overhead morning and afternoon with the syringe, using tepid water, which should keep them in a fresh condition till watered. When watering, thoroughly soak every particle of soil. The young plants should be aired sparingly until they have recovered from the check they have received. Air should gradually be increased as they become established to ensure strong, sturdy growth.

Dust the points frequently with tobacco powder to prevent and dislodge green aphids. Keep a sharp look-out for any trace of rust, and any plants which have any suspicion of this now prevalent disease should be excluded from the general stock, and all affected leaves removed and burnt. This must never be allowed to obtain a firm hold, or disastrous results will follow.

Specimen plants of any section may be grown on in a slight heat. Choose strong, vigorous-looking plants, and after they have made about 6 inches of clear stem, the points should be picked out; these should be grown on with all speed as early in the season as possible. The most suitable place for these is a shelf in an intermediate house quite near the glass. E. BECKETT.

Abraham House Gardens, Elstree.

FRUIT GARDEN.

HARDY FRUIT TREES.

CONTINUE energetically with the winter work, so as to complete it before the trees start into growth. Old Apple, Pear and Plum trees standing in the open that have become weak, and produce small fruit through poorness of the ground, may be much improved by top-dressing with loam, farmyard manure, bone-meal, and lime rubble, well mixed together, whether the ground they are on be covered with turf or not. Put turf at a distance of 3 yards, more or less, all round from the trunk, dig out the soil down to the roots without damaging them, and put in a layer of the above mixture, as much as can be afforded, making good any deficiency while putting in the new soil. Tread it firmly throughout. Surplus soil may be disposed of by placing it between the trees. It would be much better for the well-being of the trees if the turf be not relaid, and so keep the enriched space free of weeds with an occasional hoeing in the season. This is demonstrated at Woburn experimental fruit farm. Trees on ground with turf are not a quarter the size of trees on ground without turf. If the turf is not relaid, it may with advantage be made use of by chopping and mixing it with the soil.

PROTECTING FRUIT TREE FLOWERS.

There are two ways of doing this; one may be termed fixed, *i.e.*, a kind of thin covering placed over the trees when the flowers begin to expand, and so to remain until the fruit is set, and the other movable, which is put over the trees when there are signs of frost before dusk, and removed in the morning when the temperature rises above freezing point. The last-named system is the one I recommend.

Covering material should be of sufficient thickness to protect the flowers against severe frost. A good kind of material for covering is hothouse shading, fixed some distance from the trees, in conjunction with covering. A coping board 9 inches or 10 inches wide is necessary for throwing off water as well as helping to keep away frost, also strips of deal placed slantingly every 3 feet or 4 feet along the wall, with one end in the ground and the other fixed to the coping board. Fasten the top edge of the covering to the coping board, and the lower edge to the strips of deal near the ground.

A fixed covering is worse than no covering at all, whether it be fish-net of one or two thicknesses or

branches of trees. Frost does more damage to flowers when damp than when dry. Fixed coverings encourage damp by keeping from the flowers the drying effects of spring breezes and warmth from the sun. I had a practical lesson twenty years ago. I had two gardens not quite a mile apart with Peach trees in both. In one garden they had on a fixed cover of fish nets, and in the other no cover. The best crop of Peaches came from the trees without cover.

G. NORMAN.

The Gardens, Hatfield House.

THE PAPYRUS IN SICILY.

Of all the Sedges known in the world the most stately, distinct, and beautiful is the Nile reed on which the Egyptian scribes wrote their records 3000 or 4000 years ago. It is now very rare in Egypt, having vanished from the delta whence the ancient supply used for paper-making was derived, though still existent in one or two places on the Upper Nile. The plant may still be seen growing in all its native luxuriance and beauty, however, in Sicily, near Syracuse, on the banks of the Cyane, as also lower down in the tawny floods of the Anapo. According to W. A. Paton in his book "Picturesque Sicily," p. 326, "the Cyane is a wayward watercourse which meanders to and fro, lingering long among meadows and orchards. Its banks are beautified by masses of Papyrus, 'the plant of the Nile,' where only, along the margin of this stream and by the fountain of Arethusa in Ortygia, it is still found anywhere in Europe growing in its natural beauty." Again he says on the same page: "The banks of the Cyane are most picturesque and finely coloured: the green Papyrus stalks, covered with golden tassels, show against a background of yellow cane. Almond trees fill the air with the sweetness of their blossoms, and the green turf is covered with a snow of petals. Everywhere there are flowers, especially such as flourish by sweet waters and love the borders of clear flowing streams."

The Cyane is wonderfully clear and transparent "the deepest pools reflecting heaven shone with the blue of the alpine Gentian." "The great charm of the river, however, is the Papyrus, the sight of which carried our thoughts back to the days of King Hieron II., the ally of Rome, the friend of the Egyptian Ptolemies, who to please his dearly beloved wife Philistis (whose beautiful profile is to be seen on old Syracusan coins, brought the parent plant from the river Nile, or, as is not improbable, received them as a gift from one of the Ptolemies to embellish a garden for his queen on the banks of the Cyane. The Papyrus was in place so dense that a tow-line could not be used, and the boat was propelled by the boatmen and passengers dragging it forward by means of the tough Papyrus stalks."

The Papyrus is easily grown in a pot or tub, or planted out in good loam on the floor of a warm greenhouse. It may be seen in the fountain basins or tanks of gardens on the Riviera, and throughout Southern France and Italy it is grown in the open air at least, during the hottest period of the year. It is, of course, found in all botanical gardens under glass, but it could, no doubt, be grown in tubs in a moderately warm greenhouse, and might then be plunged in open-air pond or lake margins in the south of England during June, July, and August, or even later in hot seasons. In hothouses it attains a height of 12 feet to 18 feet, but even hard-grown plants 4 feet to 6 feet in height would look very distinct and effective outside in sheltered spots during summer.

Professor Parlatore formerly thought that

there were two species of Papyrus, and that the Sicilian plant differed from the Egyptian one, but that they are one and the same is now generally conceded. The Papyrus and the blue Lotus, or *Nymphaea stellata*, are often figured on Papyrus rolls, as may be seen in the library of Trinity College, Dublin, in the British Museum, and elsewhere, and it is curious to observe that Egyptian scribes and artists or sculptors generally figure the half-expanded heads, when they are shaped something like a paint-brush or carpet broom, rather than the fully-developed heads which droop all round in a globular

Syria: for instance, on the edges of the Sea of Galilee and lake Merom, in Palestine. In Europe it is confined to South-eastern Sicily, where it grows not only on the Anapus (modern Anapo) and Cyane (modern Pisma) near Syracuse, but also at San Cosimano, near Melilli, at Spaccaforno, and on the Cantara near Calatabiano. This wider distribution in that part of the island makes its ancient introduction from Egypt by the kings of Syracuse less certain. It might be a true native: on the other hand, its absence from similar waters in the south of Spain, Greece, and elsewhere in Sicily

CYPERUS PAPYRUS ON THE BANKS OF THE ANAPO, SICILY.

(From a photograph by Signor Crupi, Taormina.)

manner, and it may have been this fact that in part led Professor Parlatore to think there were really two distinct kinds as species.

F. W. BURBIDGE.

ALTHOUGH almost extinct in Egypt—its classical home—the Papyrus grows in great abundance on the rivers of Nubia, Abyssinia, and tropical Africa. It is reported that the "sudd," which is so serious an obstacle to the navigation of the Upper White Nile and of the Bahrel-Ghazal, is chiefly composed of Papyrus. Out of Africa it is found in sluggish waters in

strengthens the theory of its introduction by the hand of man. The river Anapus, which issues in the port of Syracuse, is a sluggish and somewhat muddy stream which runs almost dry in the summer months. It has, for Sicily, a longish course. At a short distance from the sea it receives a clear tributary stream from the right, which issues only a few hundred yards distant from the brilliant and deep circular spring known to the ancients as Cyane, from its bright blue reflection, and called Pisma by modern Syracusans. This spring is more perennial than the Anapo, and does not fail so much in

summer. The Papyrus grows in both waters. Formerly it grew in a small stream called Papireto, which traversed the city of Palermo. This stream was drained in 1591 because it gave rise to malaria in the town, but there is still a small square there known as Piazza Papireto, which marks the old home of the Sedge. In the fountain of Arethusa in the town of Syracuse, which is situated on an island known to the ancients as Ortygia, the Papyrus is grown and carefully looked after by the municipal authorities. C. C. LAUATA.

[In the first of these two accounts there is some confusion between the river Anapus and the pool Cyane; the distinction is, however, made quite clear in the second.—EDS.]

CORRESPONDENCE.

(The Editors are not responsible for the opinions expressed by their correspondents.)

DWARFING PERENNIALS.

[TO THE EDITOR OF "THE GARDEN."]

SIR. Because this method of reducing the height of some perennials may with impunity be adapted to suit certain gardens, localities, or other requirements, it is not likely to meet with success in all instances alike. For instance, the herbaceous Phloxes, while freely submitting to the treatment and flowering freely, though later than plants not cut down, are not in my opinion increased in value thereby. This is because they lose their chief head of bloom, for which several smaller heads are substituted. The Phloxes, however, are generally later for the cutting down, and where this is an advantage the larger panicle of bloom will, of course, be forfeited the more readily. Better results in these things may be secured by putting in good cuttings in May in a frame and growing the plants well to the flowering stage. Chimney Campanulas would be the last things I would cut down, as I think all their beauty would be lost. Any system, however, that will prolong the flowering of the Peach-leaved Bellflower (*Campanula persicifolia*) will be welcomed by many, for there is room for such things at all times. Seedlings, of course, give later and more varied seasons of flowering, but the flowers are not usually of the finest. A greater number of useful plants is found among the composite family, and, of course, among the tallest of its members. In the composite group, while there is no loss in the size of the flower-heads individually, we have a decided increase of numbers. This is most conspicuous in the Michaelmas Daisy and in *Pyrethrum uliginosum*, and is, of course, quite opposed to what one would expect in such cases; but the facts may be proved by anyone who so desires. The latter plant, indeed, breaks away so freely and quickly that it requires no check. In the harder-wooded *Aster Novae-Angliae* the breaks are longer issuing from the stems, and the amount of delay in this represents the deferred flowering later on. The softer stems of the *A. Novi-Belgii* type take less time in emitting the new shoots. Usually, however, both in the *Aster* and *Pyrethrum* some thinning of the new shoots is necessary; indeed, so crowded and so numerous were they, that much reduced flower-heads must have resulted had all been left to grow unheeded. Taken all in all, the subject is one that must ever have limited scope, whether it be of gardens or of plants. E. JENKINS.

Hampton Hill.

THE WISDOM OF ROOT-PRUNING.

[TO THE EDITOR OF "THE GARDEN."]

SIR. "An Old Practitioner" takes me to task on p. 67, and doubtless rightly so, the article he quotes having appeared in *The Garden* of December 30. Now doubtless my critic will think I must have been wandering to advocate root-pruning on December 30. Such was not my intention, and if "An Old Practitioner" is a regular writer to the Press, he will be aware that at times an article

appears weeks after being written. Other matters often crowd out cultural notes, and it is so in this case. My note was written early in October, and I note that, or the beginning of November, is the time "An Old Practitioner" advises the root-pruning, so I was not so far wrong after all. But I am not sure that "An Old Practitioner's" practice is believed in by everyone. How does the usual transplanting that trees receive in our large nurseries, say in March or even April, coincide with the above views, as it is well known many make up their fruit quarters at that period, and with great success? GEO. WYTHES.

NARCISSUS PALLIDUS PRÆCOX.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—One is pleased to see that this lovely early Daffodil has an admirer in the person of "F. H. C." (page 49). Although the writer does not usually grow this Pyrenean Daffodil under glass but in the open, it is as great a favourite with him as it appears to be with your correspondent in the issue of *THE GARDEN* of January 20. It is one of the earliest to flower here, and everyone is pleased to see again its soft-coloured flowers decorating the rock garden. It is variable, as your correspondent remarks, and this variability consists, not only in its colour and form, but also in its time of blooming. The latest form I have here is also the prettiest. It is not only purer, but is of more beautiful form than the majority of the flowers in the other clumps.

One thinks that an exchange of experience on the question of the cultivation of this Daffodil in the open might serve a useful object. In my garden, as I have previously said in *THE GARDEN*, it is one of the most satisfactory out of upwards of 100 species and varieties of the *Narcissus*. It has now been here long enough to show both its good and its bad qualities. One can, however, say that the former are many, but the latter are difficult to discover. I am well aware that many cannot grow *N. pallidus præcox* in their gardens. The light, sandy soil seems to suit it, but it appears to like still better to be on the rockeries, where it can receive sufficient moisture with free drainage. Summer watering does not seem to do it any harm, nor do the drier rockeries, too far from the water to get more than a limited a very limited supply in summer, make it less successful. One is thankful to be able to speak thus cheerfully of this Pyrenean Daffodil, and I hope that others with whom it may be equally at home will help to persuade some of those who have not tried it to experiment a little by trying whether or not it will grow in their gardens. I am aware that some of our leading private growers of Daffodils hold very pessimistic views about the establishment of *Narcissus pallidus præcox*. Here, at any rate, it never fails, and this in either sun or shade. There must be many other gardens in which it is equally satisfactory. If some others will tell where and how it flourishes they will do a service to some who care for one of the loveliest of the flowers of spring. S. ARNOTT.

Carsthorpe, by Dunfries, N.B.

FALSE IDEALS.

[TO THE EDITOR OF "THE GARDEN."]

SIR. I should like with your permission to add a few more words upon this important subject.

In the present day, when the value of natural beauty in the garden has been recognised to a considerable extent, the inartistic process of clipping to which evergreen and other shrubs are subjected still remains largely in vogue. Throughout the length and breadth of the land public and private gardens are to be seen whose beauty is marred by the prim and monotonous contours of the shrubs and evergreen trees with which they are planted, that exhibit a weary uniformity of outline in place of the natural and individual grace of expression which is their birthright, appearing from a little distance like gigantic green mole-hills rather than objects each of which possesses the potentiality of distinctive structural attraction. Where it is deemed needful that shrubs should retain the same dimensions for many years, the result is naturally most easily obtained by annual sheerings, that reduce them to squat, dome-shaped

masses of greenery utterly devoid of all beauty of form. If repression is absolutely necessary, it may be effected by a careful cutting out of the most prominent branches without unduly interfering with the characteristic expression of the subject, but it is invariably preferable, where shrubs have become crowded, to entirely remove the less decorative and to allow the remainder to assume their natural proportions. Of the examples of misapplied ingenuity to which the designation of "topiary work" is applied, if any place can be benefited by their presence, it is the precincts of the mechanical museum, but not the garden.

The "shrubbery" is too often an instance of "false ideals." It is in numberless cases a heterogeneous jumble of many beautiful things which exist, rather than live, under conditions that render liberty of expression impossible. Each individual specimen should be allowed sufficient space to display to the full its distinctive attributes of loveliness, and should, where possible, be surrounded by examples of the same or allied genera in order that a broader effect may be produced. The same careful study of artistic effect should be bestowed upon the laying-out of the garden as is given by our painters to the composition of their pictures, for, to be beautiful, the garden must be a picture in which no jarring elements of colour or form obtrude themselves upon the eye.

The value of broad colour-effects is ever instilled into our consciousness by Nature in the azure expanse of sky and sea, the blue-green of the Scotch Firs flanking the mountain slopes, the scarlet of the popped field that glows afar from the steep hillside, the saffron carpet of hosts of Daffodils in the orchard-mead. The author of "Bethia Hardacre's Year-Book" was so enamoured with the fascination of pure colour, that she contemplated the production of a volume some of the pages of which were to consist merely of one exquisite tint.

Beautiful as are breadths, gradations, and occasional contrasts of colour, a meaningless medley of bright hues is irritating to the senses and intelligence. Let it be for a moment imagined possible that a canvas, consisting solely of concentric circles, triangles, stars, and other geometrical figures in brilliant colours, could be exhibited at the Royal Academy. What a storm of derision and disapprobation would arise at the audacity of such a production being called a picture! Yet our garden-pictures are still in many cases allowed to be disfigured by similar atrocities.

Perhaps one of the chief reasons for the continuance of the carpet-bedding mania is the apathy evinced by numerous owners of gardens as to the style pursued in their own domains. The writer of "Cold Weather Notes" (p. 58) hints at a dim future when the two schools, namely, that which takes the teachings of Nature for a guide and that which is nothing if not artificial, shall combine into one harmonious whole; but surely incongruity rather than harmony would be the result of a combination of the meretriciously gaudy carpet-bed and the refined beauty of an artistically arranged herbaceous border. In the same article the terms "disorder" and "negligence" are used as applying to the effects obtained by those who aspire to follow the suggestions of Nature rather than to practise the devices of artifice, and, together with the term "confused muddle," by which the same method has before now been described, are applicable only to instances where infelicitous disposition of the plants employed has obscured the inherent merits of the system.

An idea has gained wide credence that the objectors to pattern-beds are equally intolerant of the plants employed in their composition. This, however, is in the case of true gardeners an entire misapprehension. It is the abuse and not the use of these subjects that is condemned. Tuberous Begonias, zonal Pelargoniums, annuals, and other bedding plants are often of extreme value in the garden, and in like manner the attractions of the hardy plant border may be considerably enhanced by the use of many plants that require annual lifting and protection during the winter months, such as Dahlias, Camas, *Salvia patens*, *Lobelia fulgens* in many cases, and others.

S. W. FITZHERBERT.

DWARF POINSETTIAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—As the author of the notes referred to by Mr. Crawford, I may state that my experience of their culture extends over thirty years. I quite agree with Mr. Crawford that the stock plants should be retarded as far as possible, but unless they are cared for when they would naturally start into growth, it would be useless to expect good results. I have tried the experiment of keeping plants back, with the result that only weak growths can be had; and though these may be propagated easily, they never make sufficiently strong growth to produce good heads of bracts. If strong, healthy plants are topped at the time I suggested, they may be cut down to within 6 inches of the soil, and if carefully treated these will make two or three breaks, and if potted on these will make fine heads of bracts. The one great advantage of propagating early is that the first growths are stronger, and the old stock plants, which are apt to get infested with insect pests, besides taking up more room than the young ones, may be discarded. When necessary to make the most of stock, the old plants must be potted on and given every encouragement to make strong growth; the tops will then be as good as those taken from the young plants. I have grown plants propagated from old stock late side by side with those taken from strong young plants, and the former have always failed, while the latter have invariably proved a success. With proper accommodation, the labour and trouble entailed are far less than in keeping old plants about. The Poinsettias make such a bright display at a season when there is little else of the same colour, and when flowers are most appreciated, that I think they should be much more extensively grown than they are. I now have one head of bracts which was cut on Christmas Day, and though now past its best, it is still bright.

A. HEMSLEY.

P.S. Has Mr. Crawford succeeded under the system he suggests?

ARALIA (FATSIA) JAPONICA IN THE OPEN.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—"A. L. L." draws attention (p. 28) to the decorative properties of this Aralia, and writes feelingly of the exquisite effects produced by large specimens thickly studded with their pale flower-clusters in the dim mid-winter days. It is, however, only in certain climatically favoured districts of our islands that this subject flourishes in the open air. In such spots specimens attain huge proportions, one fine example that I know of having a circumference of 50 feet. Although it is at the time when our gardens are well-nigh destitute of floral attractions, that the charms of this Aralia are most insistent, the noble form of its deep-erect, bright green leafage, on whose glossy surface the sunbeams glint, renders it ever a graceful vision. Since the lilies belong to the order Araliaceae, the formation of the inflorescence of the subject of this note naturally bears a striking resemblance to that of the lily.

W.

CLERODENDRON TRICHOTOMUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—The notes that appeared on page 66 of the present volume and pages 367 and 506, vol. lvi., were, I think, primarily suggested by a reference of mine to the decorative effect produced by this handsome subject in South Devon gardens. The climatic conditions enjoyed by the south-western sea-board, along which the flagging tide of the Gulf Stream slowly glides, are especially favourable to the culture of interesting shrubs and trees of doubtful hardiness. Indeed, if the dwellers in that exceptionally favoured locality were restricted to the practice of one phase of gardening alone, that of the growth of the tenderer flowering shrubs would undoubtedly afford the greatest measure of variety and charm. Fine specimens of the subject of this note when in full bloom are objects of great beauty, the plentiful display of flower clusters with their white, red-calyced blossoms being

remarkably effective, while the sweet perfume of the flowers floods the surrounding air with fragrance. One of the most striking specimens that has come under my notice was growing in Lord Hechester's garden at Abbotsbury Castle, Dorsetshire. It was about 8 feet in height, with a spreading head of about the same diameter, and at the close of August was covered with bloom. An illustration of the plant in question appeared on page 320, vol. li. *C. Bungei*, or *fetidum*, alluded to in one of the above-mentioned notes, is distinctly inferior to *C. trichotomum* in its ornamental qualities, the tightly-packed flower-corymbs being of a rather unpleasing shade of pink, while its stiff, upright growth is deficient in grace, though the large heart-shaped leaves impart a certain nobility of form. The unpleasant odour emitted from its bruised foliage is responsible for its specific title of *fetidum*; but in this respect it is not singular, the subject of this note possessing the same characteristic, though in a less degree.

S. W. F.

SWEET BRIAR ROSES FOR EXPOSED POSITIONS.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Would you kindly let me know in your valued paper which kind of Sweet Briar is most suitable for growing close to Birmingham in a cold and rather exposed position, and also what class of soil, manure, and treatment is most suitable to make its growth a success? E. J. RAINSFORD.

[If you desire these to form a hedge, the common Sweet Briar would perhaps be the best kind to select. It is very hardy, and as the plants are raised from seed there is no trouble from wild suckers such as one experiences now and then with budded plants of Lord Penzance's hybrid Sweet Briars. These latter make delightful hedges, their blossom, although fugacious, being very effective whilst it lasts. The best and most brilliant crimson kind is *Anne of Gierstein*. Other good sorts are *Amy Robart* (pink) and *Lady Penzance* (coppery yellow). This latter is not quite so free as the two former, but it is perfectly hardy, as they all are. All have fragrant foliage and produce gorgeous fruit in autumn. The Sweet Briar revels in a good deep loamy soil rather inclined to clay, but before planting have the ground trenched, incorporating with the soil some well-decayed farmyard manure and a little old mortar and burnt garden refuse, if procurable. Sweet Briars may be planted any time between October and April, but if planted now, see that the roots are not allowed to get dry, but rather dip them in a bucket of thin mud beforehand. In the case of the common Sweet Briar we do not care to plant bushes too large. Those from 2 feet to 3 feet in height are strong enough. If a thick hedge is desired, plant a double row, allowing five plants to the yard. One year after planting cut down within 12 inches or 15 inches of the ground. The subsequent treatment would consist of removing dead and crowded growths in autumn and a rather severe pruning every three or four years, which would induce a plentiful supply of new growths. A good watering now and then during the summer with diluted stable or cow-yard drainings is an excellent stimulant for these and other Roses employed as hedge plants. —EHS.]

THE NEW ZEALAND FORGET-ME-NOT.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Your Dunedin correspondent, Mr. A. Bathgate, in his interesting note on the New Zealand Forget-me-not (*Myosotidium nobile*) expresses a wish to know if the specimen figured in THE GARDEN (page 150, vol. l.) grew near the sea. Though doubtless not so far removed from the sea as to be entirely unaffected by the Channel breezes, the locality in question is by no means on the coast, being roughly speaking some ten miles distant from the shore. In South Devon this handsome plant also flourishes and blooms well six miles from the sea. A friend who had met with the plant in its native habitat fully confirmed Mr. Bathgate's statement as to its growing within reach of the salt spray, but I imagine that vigour depends upon the rooting medium rather than upon

salt-water sprinklings. Certainly the Devonshire example above alluded to owes nothing of its robustness to the latter treatment, which I should be inclined to consider waste of time and labour. The compost in which it is planted should, however, consist largely of sea-sand. In the case of the South Devon specimen the latter ingredient forms one-half of the soil in which the plant is growing, the remainder being composed of loam and leaf-mould with which a certain proportion of road-grit had been incorporated, while, according to the note accompanying the illustration referred to by your correspondent, sea-sand had also been largely used. In cases where failure has attended the culture of this plant in the neighbourhood of the south-western coast-line, non-success may be attributed in a great measure to the omission of sea-sand from the compost.

I remark that in his note Mr. Bathgate states that the local New Zealand name for *Myosotidium nobile* is Chatham Island Lily. This title has also been bestowed, possibly incorrectly, on *Iris (Morea)* *Robinsoniana*, a handsome plant, whose white blossoms certainly have a better claim to the title "Lily" than have the many-flowered trusses of the *Myosotidium*. This *Iris*, also known as the Wedding Flower, was discovered at Lord Howe's Island, off the east coast of Australia, and its successful open-air culture is attended by even greater difficulties than encompass that of the New Zealand Forget-me-not, the only scene of its flowering in the open in this country, as far as I know, being the Isles of Scilly, although the fine specimen in the succulent house at the Royal Gardens, Kew, I understand, blooms yearly.

SOUTH DEVON.

THE SWEET PEA CONFERENCE.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—While to all appearance the promoters of the Sweet Pea bicentenary celebrations have secured sufficient support to induce them to proceed with their proposal, it is gratifying to see that it has been deprecated so ably in the columns of THE GARDEN. That the conference will be well organised seems certain from the names which have appeared in connection with it, but I think it is more than doubtful if the gardening public will support it by attending in any number. The question of classification and that of "too-much-alike" varieties appear to bulk largely in the minds of the promoters. One is curious to know how the specialists think of dealing with the former, and equally curious to see how they will settle the latter. I take it that it is impossible to settle the latter by comparison of cut blooms alone. A trial of the varieties in growth would be required in addition. Even if this followed, is it probable that the decisions of the conference or its committees would be accepted by the raisers of Sweet Peas? In a year or two the flood of new varieties is likely to be greater than before, and there is not the most remote chance that their raisers will submit to the judgment of any conference on the point of similarity to those already named. The Royal Horticultural Society was the proper body to approach when such a proposal was mooted. It could have taken it up, not only with more authority, but also with proper facilities for bringing it to a successful issue. At the same time, I do not admit that the movement is either necessary or likely to do any good to one of our most beautiful annual flowers.

ALPHA No. 2.

[We agree with our correspondent, "Alpha No. 2," and others also who hold that this is a matter that might have been as well or better dealt with at any sitting of the Royal Horticultural Society's floral committee. He has drawn attention to two important points, namely, that all such plants should be judged as they grow rather than from gathered bunches, and that in all probability no amount of conferences will deter raisers from the future production of an equally large number of varieties. At the same time we do not wish to actually discourage any undertaking that has for its object the bettering of any class of popular garden flowers, and with this letter we desire to close our columns to any further expression of

want of sympathy with the excellent horticulturists who have initiated the movement. We trust, however, that they will impress upon raisers that the Sweet Pea is, above all things, a climbing plant, and that the dwarfing now going on is a distinct debasement of its dignity. Also that this charming flower in its best form should have the upper wings well shaped and widespread, not half-folded a fault that spoils many varieties, among them the otherwise handsome Saidee Burpee. Eds.]

THE STRIPED HELENIUM.

[To the Editor of "The Garden."]

SIR, - I regret to find I have unwittingly misled your readers. The plant I described on page 55 as *Rudbeckia* should be *Helianthus*. Mr. Simpson's

ARCHES OF CLIMBING PLANTS IN THE GARDENS OF SWANMORE HOUSE, BISHOP'S WALTHAM.

request for a plant led to my looking up my catalogues, with the above result. Now my attention is drawn to it, I can recollect that the stems have the peculiar square winged appearance I have noticed in other *Helianthus*, but the flowers were so like, except in colour, those of *Rudbeckia* Newmanii, that I quite accepted the description of the nurseryman from whom I got my plant.

Woodside Park,

T. J. W.

THE KITCHEN GARDEN.

DEEP CULTIVATION.

THIS subject has lately been touched upon by some of THE GARDEN'S correspondents, and it is to be hoped that its very great importance may lead to more being written upon it. Perhaps the most

practically useful contribution to the discussion would be the actual experience of good gardeners up and down the kingdom, for soils and the treatment best for them vary almost to infinity. A fallacy too commonly met with in horticultural writings is the proponing of one's own successful management of a soil or a plant as though it were an infallible prescription for the whole planet. It was my privilege to occupy the chair at the first technical education lecture on horticulture in my country-side, when the lecturer, an otherwise able man, devoted his first hour exclusively to methods of drainage, the soil of the district being on dry chalk, with the nearest water 100 feet below the surface. A far more harmful mistake is made by those who make deep cultivation to mean trenching, and recommend it as a general panacea. Gardeners might with great advantage learn more from the scientific farmer than they usually

will have to be answered. First, that of shallow or deep cultivation - is this ground to be dug one spit deep or more? Nearly everywhere the answer will be "more." And then the second and critical question arises does this mean trenching or bastard-trenching, *i.e.*, must the lower spit be brought to the surface or only broken up *in situ*? The wise gardener will make inquiry, or, still better, a careful personal study of the practice and the results of the best farms and gardens of his own locality. But he should not be ignorant or forgetful of the general principles upon which the entire consideration hangs. A very little thought will show that to trench regardless of the character of a soil is to violate those principles, and, indeed, common sense. The upper spit of his ground is the gardener's most precious possession, created by things which he cannot have on demand, whatever his wealth, namely, weather and time. The very

do; but in this matter I think there has been a "corrupt following" of Mr. Meech, of Tiptree, whose zealous advocacy, many years ago, of deep tillage was often wrongly and injuriously interpreted. The right treatment of the soil in this respect is even more important to the gardener than to the farmer. The farmer has but few crops which remain on the ground for more than half the year, and therefore has frequent opportunities of mending an ill-treated field by re-working and following. But in the kitchen garden the Strawberry plot will not be dug for, say, three years, and the Raspberry quarter for at least six, while the ground under the fruit trees may stay undisturbed for a generation or more. In the flower garden, if a new herbaceous border is to be made, it must be made with the knowledge that the soil cannot be dealt with *en bloc* for several seasons. It is therefore all-important that it should be treated not only thoroughly, but safely. Two questions

school children can now tell him, in chemical terms of gas and acid, how sun and air, rain and frost, have crumbled the rocks into soil, and how the countless generations of plants have helped on the manufacture of the "top spit" by their life and death. Some of us find a real pleasure in handling the mellow, kindly upper soil; the breath of life has been breathed into it, and it has become almost as much a friend as the flowers it bears. It seems murder, and it usually is murder, to bury it beneath 1 foot of crude, dead subsoil. Apart from fancies, it is certain that many a field and garden have been ruined for years by this reckless trenching. The common argument in its favour runs thus: that by bringing the bottom spit to the surface we create a new top spit, while the buried top spit becomes a rich, deep root-run for the crops. But the surface soil, when buried and sealed up from the influences of sun and air, is no longer the wholesome, vivifying material that it

was, while the new surface must be submitted to a long cycle of such atmospheric influences before it can acquire the virtues of the old.

My own neighbourhood, in the north-west corner of Hampshire, may afford an illustration. The average soil is a flinty clay of moderate stiffness, running from 6 inches to 1 foot in depth. Beneath this is a streak of tenacious brick-clay, and then the chalk rock, of a dry, porous quality. Deep cultivation was tried on some of the farms at the time when its universal benefits were being enforced by the doctrinaires. The tillage was carried down to the chalk, and the three layers were more or less churned up together. The unanimous testimony of the most intelligent farmers is that the experiment was a failure, causing long-continued infertility, and they have reverted to a shallow ploughing of 4 inches or 5 inches. As to horticulture in the same district, I have under my eyes a large piece of new vegetable ground, broken up out of old pasture land by a neighbour about eight years ago as an adjunct to his kitchen garden. Contrary to my advice, he trenched it, burying the excellent thick sod beneath the clay underspit. The produce of that ground is to-day entirely inferior in quality and quantity to that of some new allotment strips made out of the same pasture by simply breaking it up to one spade's depth.

A far safer method is that of bastard-trenching or double digging, by which both spits are broken up, but the lower is kept in its original position. On many soils this is immediately beneficial, but it is not invariably so. Nearly the whole area of my own small garden has received this treatment, piecemeal, during many years without such general advantage to all crops as I had reason to anticipate.

The behaviour of a plantation of Raspberries in particular caused me to reconsider the matter. The quarter for these was somewhat laboriously prepared by double digging, both spits being well manured. Excellent canes were planted, but in spite of every attention in the way of mulching and so forth, their growth and yield of fruit have never been satisfactory. They have evidently suffered from want of moisture, the Raspberry's main requisite. On the other hand, a few canes in a much hotter corner of the garden, on ground which has never been dug to any depth, grow and bear much more freely. Here, then, is a useful object-lesson, and I interpret it thus: The layer of stiff clay which constitutes my bottom spit is necessarily broken, in the process of double digging, into rough lumps, too coarse to allow of a full capillary attraction of moisture from below upwards, while they offer a too ready passage for the rainfall to run away into the chalk. The failure of these Raspberries has been of great service in leading me to a more rational and fruitful handling of my soil. I do not now ever make any permanent plantation upon ground freshly double-dug, but plant it once, or even twice if feasible, with Potatoes or some transient crop, which admits of a brief fallow and a second or even third pulverisation of the lower spit. This is not so tedious as appears if foresight is used and the garden routine planned two seasons in advance. On many other soils of course such a lengthy procedure is not necessary; I have mistaken my own as a proof that no one general law of treatment can be laid down for all places.

The very expression "deep cultivation" is apt to set beginners in gardening on a wrong track. It is common to read such advice as "dig deeply, and then your plants can send their roots right down for food and out of the drought." Now there are deep-rooting plants, but there are vastly more which love to keep their roots within the warmed and aerated surface layer of soil. A spade pushed along horizontally 6 inches or 7 inches below the surface of a mixed border will remove the bulk of the plants unharmed. Or throw an inch or two of sweet soil on such a border, or within reach of a fruit tree, and see how the feeding rootlets rush up into it. Even our great forest trees feed in the same way. My stores of turf, leaf-mould, &c., are stacked a few yards from the stem of a huge Horse-Chestnut; if not moved for a few weeks they

become like door-mats of its fine fibres. It is well ascertained that the unfruitful condition of so large a proportion of our older orchards is chiefly owing to their over-deep planting. We seem to have only recently learned how to plant fruit trees. A curious instance of the discomfort of plants at an unaccustomed depth has come in my way. I flower a good many Narcissi annually under glass; the pots are plunged in ashes during the winter. Two or three times it has happened that an over-thick covering of ashes has been thrown over them, with the result that the long white roots come straight up out of the pots, like the antennae of some lost creature groping upwards to the light. We are always being told to trench manure in deeply, but the deep burying of manure is either wasteful or injurious; either it is below the reach of the plants, or it entices their roots to an unwholesome depth. It sounds paradoxical to say that deep cultivation, from the feeding point of view, should be done upwards as well as downwards, but I believe it to be true. Garden refuse, for instance, should not be trenched in deeply, as is too often advised, but rotted in heaps with lime, or burned, and spread little by little on the surface, where it can be worked in by the hoe. A surprising fertility can be maintained by these slight films constantly repeated. How generally the elementary truth is ignored that plants, like babies, can take their nutriment only as liquid, and therefore want all solid food put within grasp of the rain, and not below it! Undoubtedly as we advance in our knowledge of artificial manuring, which as yet is in little more than the empirical stage, we shall more and more feed our plants by small potable doses administered from the surface.

The foregoing must not be read as a blank negation of the value of deep cultivation. Deep cultivation is immensely beneficial if its object is understood, and if it is accordingly carried out in a purposeful way. That object is, in a word, *the opening up of communication*, primarily with regard to the water supply. Water is a plant's first requisite; it can grow to some extent without light, it can grow without soil witness the Hyacinth in its glass—but it cannot grow without water. The perfection of our crops of flowers, fruit, and vegetables varies very much in the same ratio as that of the water supply. We have not yet learned to call down rain from the sky, nor even to be ashamed of and to remedy our gross waste of that which falls. But by maintaining our soils in the fittest possible texture we can do much to secure to our crops the whole available supply of moisture from both above and below. In the first place, there must be a free passage of the rainfall downwards, "not rudely fast nor obstinately slow," carrying the food solutions gently, as it passes, to the little mouths of the rootlets. In farm work it may happen that the constant sliding of the plough and tread of the horses at the same level compresses a dense clay into an impervious "pan," and this must occasionally be broken by a deeper ploughing if the soil is not to be water-logged. To make a garden on certain formations, a pan of rock or lime incrustation may have to be broken up by double digging. But this work has a far more common usefulness in leading the water upwards. If we can effect a finer granulation of the second spit, we multiply and deepen the slender capillary tubes which continually pass the moisture up to the layer of soil where the fine roots are ranging. Although it may sometimes be to drain a wet soil that we dig so deep, nevertheless the aim is still the same—to supply moisture. It is only after a residence of stagnant wet that this healthy capillary action can be set up. As the right movement downwards of the rain from above and upwards of the moisture from below depends upon the granulation of the soil, so its warmth, aeration, and other desirable conditions depend in turn upon this movement. But this granulation, this ideal spacing of the soil particles, is not necessarily obtained by the simple putting topsy-turvy of the two spits, nor even in all soils by double-digging once and for all. If we break the under spit into hard lumps with cracks between them, we do not assist, but interrupt the capillary action.

There may be soils in which, by some geological vagary, the under spit is of better mechanical and chemical constitution than the upper. And there are river deposits of uniform alluvium 12 feet in depth—I have seen one such on the Norfolk coast being trenched four spades deep. But such soils are very rare, and even then a long exposure to the atmosphere is necessary to quicken material which has lain so long cold and inert. The general conclusion seems to be that trenching proper is rarely advisable, while bastard-trenching is usually beneficial, but should in many soils be repeated once, if not oftener, before the establishment on the ground of a permanent plantation. If this cannot be done, then, contrary to the prevalent doctrine, such soils will be more productive if never dug more than one spade deep, but gradually deepened by surface applications.

G. H. ENGLEMEYER.

I HAVE read with interest your correspondent's remarks in the issue for January 20 (p. 46) respecting my article on the above in THE GARDEN for the previous week. I am not in the least surprised to find that some exceptions are taken to what I there said, for, as stated then, I know few people agree with me on this subject. Mr. Hall considers my advice much too brief, and he thinks there must be some mistake. He questions how the hungry subsoil brought to the surface can be brought into a fit state for seed-sowing, &c. Now, I am quite sure Mr. Hall, as a practical man, will agree that the influence of the weather, light, and air does a very great deal towards perfecting (it matters not what the nature of the soil be) the surface for this operation, equally as much as when trenching is performed in the ordinary way. Nevertheless, I do not pretend to say but that some little difficulty may be experienced for the first season, especially should the weather be unfavourable and on land that is of a stiff, retentive nature. But surely this is easily overcome by drawing deep drills and introducing a little fine porous soil for the finer seeds. I need not say anything about the sandy soil for sowing, as I think none will question that little difficulty will be experienced in sowing in this, even if it be pure sand. If Mr. Hall will take the trouble to read my article again, he will observe I advocate working in plenty of manure, garden refuse, &c., which in time will of course help to improve the nature of the soil and make it in a workable condition. Mr. Hall also says he knows it will take nearly a lifetime to bring clay into anything like a suitable surface for general garden crops. Here I respectfully beg to differ, for I can prove—and indeed it can be substantiated by scores of people—that land treated as I have advised eight years ago is now in a splendid workable condition, and will grow successfully almost any kind of vegetable.

My remarks applied solely to the kitchen garden. Now in making a kitchen garden it is generally supposed it will have to do duty for many years, possibly for generations; therefore surely it should be the aim of those in charge to have the greatest depth of workable soil possible, and how can this be accomplished unless a thorough system of trenching is carried out? It will be patent to everyone that if this is done, the first top spit buried at the bottom will eventually be brought to the surface again to do duty; consequently the whole of the soil to the depth of 3 feet becomes changed. And I assure my readers good soil buried at a great depth is not lost, for in dry weather especially many of our deep-rooted subjects will find it out and benefit by it considerably. I carefully noted last autumn, when taking up one of our principal Onion beds, that the roots had penetrated fully 3 feet. It is the duty of everyone to produce the greatest bulk from a given space, and I am thoroughly convinced that fully double the quantity of vegetables can be obtained by deep cultivation on the same sized piece of ground than from that treated in the ordinary way. This is an important subject upon which I shall have something further to say in the future. Deep cultivation means better and more profitable crops.

E. BAKER.

Abraham House Gardens, Elstree.

FRUIT GARDEN.

VINES IN THE OPEN AIR.

IN complying with our secretary's desire that I should write a note on the cultivation of open-air Vines, I must premise that, although this subject is my hobby, I cannot claim to be a scientific instructor in this branch of fruit growing, but only to have studied the matter, collecting and comparing facts, and growing as many varieties as possible, but with only odds and ends of time to devote to this most interesting subject.

I first took notice of open-air Vines in the London district in the hot summer of 1868, and the two following years gave me opportunities of further observing that in country districts as well as in the metropolis open-air Grapes could be ripened, and thoroughly good and handsome bunches produced.

On changing houses in 1872 I selected one with the back almost due south, and instructed a gardener to plant two Vines there, preparing the border specially for them, as the soil was clay. These Vines were Black Hamburg and Buckland Sweetwater. They grew apace, and I took some good black Grapes off the Black Hamburg in 1874. A friend advised me to procure Clement Hoare's work on the growth of Vines on open walls, and soon I knew all that writer's rules by heart, and

fit for it. I saw the two small casks in the fermenting stage.

At this point I must refer to the flowering of open-air Vines in October, 1878. I saw it in several counties, and I saw Castel Coch on November 9. The Vines were all in flower, and many had passed that stage and had well-formed Grapes. The explanation of this phenomenon is that with a long warm summer we had a warm and abnormally wet August, succeeded by a fine warm September. And this precocity or special fruiting was followed by the only year that in twenty-seven years of Vine growing I can call really bad. 1879 was bad. The year 1888 came, I think, next nearest to a failure of any of these other years as far as my observation has extended; July, 1888, was cold and wet following on a cold June, and August only improved on the 58 average temperature for July by 1.2, including the hottest day of the year, the 10th of the month, the maximum being 87.7.

To those who never tire of depreciating our climate, and who say that we cannot ripen Grapes in England, I beg to reply by calling their attention to a simple fact. I cut my Grapes in 1888 about October 10, and immediately went to France, and about forty-eight hours after cutting my own I went into the market at Rheims and closely

is, the Vines were crippled. Both the fruiting canes and the new ones should have been pruned right out and a "Sabbatical" year's recuperation allowed them. If this had been done there would have been none of the Vine diseases which were rampant in 1894, and the great expense of chemically cleansing and stimulating the Vines to produce a vintage which when produced was in my opinion, in the first place, not wanted, and, in the second place, very inferior, would have been saved. Without the wines of that year those of 1893 would have fetched as they deserved better prices, and the wines of the following year, though generally good, would have been far better, more abundant, and more remunerative to the growers.

I should very much like my readers to consider this matter fairly and without prejudice. Whatever may be done under glass in the management of Vines, I claim for them in the open every reasonable consideration. If the quality of Grapes and the wine made from Grapes off old Vines is better than that from young plants, then this is a special reason for respecting the strength and health of the Vine. I also submit that strong manures, or those of a suddenly quick and stimulating action, like blood, should be forbidden. It should always be remembered that the best wines grow in poor soil, calcareous, chalky, gravelly, slaty schist, &c. If it be true, as Clement Hoare says, that the Vine outlives every other "tree," surely that is a natural instruction to us how to treat it. If, as it advances in age, a large part of its roots rise towards the surface, should not the spade and the plough be rigorously excluded from their neighbourhood, and only the hoe and the fork admitted?

There is also a serious objection to the use of chemical applications to cure diseases, which are, to at least some extent, the result of a greedy system of cultivation. It was not greedy for the viticulturist to take all that Nature provided so richly in 1893, but he ought to have guessed (if he did not know) that then his Vines needed rest. Only seven years had passed since the disappearance of mildew in an epidemic form, and the renovation of the vineyards by grafting French varieties on American roots had almost entirely got rid of the damage done by *Phylloxera vastatrix*. An enormous increase took place in the quantity of wine grown—50 per cent. did not cover the increase in the production of some of the best-known claret vineyards. Commercially the mildew years did very serious harm to the claret trade. If 1886 had been eliminated, it would have been better for everybody concerned. If it had been a "Sabbatical" year, then 1887 would have had the immense advantage of being not only a very good, but also a very abundant year—cheaper no doubt, but far more profitable.

It may here be usefully remarked that the application not of one for that seldom succeeds—but of repeated washings of the bouillie bordelaise is risky, as was shown in one of Messrs W. and A. Gilbey's circulars. A vineyard in the Médoc was named by them, in which the effect of counteracting the mildew in this way had an undesired and untoward effect. The Vines were so stimulated by these dressings that they made an unhealthy and precocious autumnal growth, did not shed their leaves as a rule, but were caught and, to a very serious extent, destroyed by severe frost in November.

The mention of this circumstance brings me naturally to the question of when Vines should be pruned. Unhesitatingly I say prune in October.

Along with the question of how to prune, which I shall go into separately, it is primarily a consideration of what is best for the plant both presently and in the long run. The growth of a healthy Vine is so great that it both invites and demands suitable management and control, and we must adopt the plan that will best preserve its health and strength in other words, its fruit-bearing powers. Autumn pruning causes the least shock to its system and the least loss of sap, which we call bleeding indeed, generally there is none at all in October, and the wounds caused by pruning dry naturally before the advent of frost severe enough to hurt the plants.

On the other hand, the alternative of spring

Sauvign, 13 years old

Trebbiano, 10 years old

Bouill, standard 9 feet high

FIG. 55. CLEMENT HOARE'S LONG ROD TRAINING.

found I had made a bad beginning by allowing Vines on walls to fruit before their fifth year, although by this time the Black Hamburg had attained to the necessary 2½ inches in circumference.

In 1877 I had the first opportunity of observing Vines in different parts of France, and very soon formed the opinion that we could grow as good in England in some seasons, and at all times nearly as good. I also exchanged English Vines for French ones, with friends in the celebrated wine-growing departments; and so for some years I had Pineau Noir from Champagne and the Clos de Vougeot, Carbinet Sauvignon from Chateau Lafite, and sundry others.

I had good Grapes in 1878 on my Black Hamburg and Buckland Sweetwater, and according to Hoare's rule I pruned these two Vines in October. Had I not done so I have no doubt they would have flowered and tried to fruit a second time that year, as many others did, as I will notice later on.

Early in 1876 I heard of Lord Bute's new vineyard in South Wales, and went to see it, taking good note of everything about it, and described it in a letter published in the *Vines*. The slope of this vineyard on the south face of the hill of Castel Coch is very beautiful, sheltered by plenty of timber above the odd castle, and by other hills all round, except due south, where the view extends to the Bristol Channel, five or six miles off. Lord Bute made the same mistake as I had done; he made his first wine in 1878, before the Vines were

examined those on sale there. They were no better, scarcely so good as mine. No doubt the Rheims market Grapes were taken for the most part either from vineyards or gardens in which the Vines were grown as bushes or espaliers, with a few from cottage walls, and my Grapes were grown on a south wall in a suburb of London. But whatever disadvantage the Rheims Grapes laboured under by being grown in the open was, I think, not unfairly matched by my Grapes at that time not getting the sun until after 12 o'clock. I may here remark that in such years as 1879 and 1888, besides the low temperature and absence of sunshine, there is excessive moisture and also a more smoky atmosphere, house fires being maintained almost continuously throughout the season.

If the clerk of the weather would only predict the main characteristics of the weather of such years, we might make good use of them by making them "Sabbatical" years. The idea of a "Sabbatical" year has very much to recommend it, especially in the case of Vines. I include it in the calculations I have made with regard to the cost of planting and management of vineyards when consulted about whether they will pay in this country.

Leaving the theory on one side, let anyone, whether connected with the wine trade or not, consider this: The great 1893 vintage in France severely taxed the Vines, which not only during the 110 days that it takes to make a vintage, but for a month besides, had no more than half an inch of rain, and in some places none at all. The truth

pruning causes certain loss of strength by bleeding, and this often continues to a serious extent. I am at this moment thinking both of French and English Vines. Admitting for a moment that the recuperative power of the French Vines, with more sunshine than ours have, is greater than ours, they also have more risks to encounter, e.g., their earlier bud-pushing and flowering exposes them (two years out of three) to dangerous spring frosts that ours escape. In either case the Vine wants its whole strength, uncrippled by bleeding, to go on and accomplish its annual task. To my mind there is something more than adopting an opinion and practising a system in this matter, for, unless I am greatly mistaken, it will be difficult, if not impossible, to name any other plant the equal of the Vine in the open air in repaying intelligent care bestowed liberally and regularly upon it.

Judging from my own garden and from others, I think this must be called a good Grape year. The best row of Vines in the middle of my garden is the subject of a sketch I made in the middle of this month of September, just as the standard Brandt with over forty small black bunches (seen on the right of fig. 55) attained maturity. This Vine is nine years old, very strong and wild; it resents control, and is the earliest ripener within my knowledge. Its foliage is rapidly assuming splendid scarlet and purple tints. I mean to graft some more valuable variety upon it. The Brandt is about 9 feet high, and the top rail of the supports reaching to it is about 7 feet from the ground. The middle plant is Trebbiano, sixteen years old, with only half a dozen small bunches. This also I intend to graft with better open-air varieties. The Vine on the left is a Syrian, thirteen years old, with very strong stout wood. It has three bunches of its own, only one of which is of the usual immense size. The fate of these is to go under pie-crust, as if they were Gooseberries. One year I put them in with all the others to make wine. There is a graft on the right arm of this Vine with six bunches of red Grapes, but these have got mildew this year. I am not sorry for having tried

on the south gable of Mr. Will Taylor's house at Hampton. It is higher on the wall than I should grow it, and involves considerable ladder work to train and develop it (fig. 56). Most possessors of such a Vine would get little or nothing from it. It is the common neglect or mismanagement of wall Vines that keeps back the general and profitable cultivation of them. This one of Mr. Taylor's is a great advance on ordinary methods, and the result is most encouraging. Mr. Taylor received this Vine from Germany under the name of Reine Olga. - Reprinted by permission from the *Journal of the Royal Horticultural Society*, 1899.

KITCHEN GARDEN.

AUBERGINES.

THESE are vegetables finding little favour in this country, but on the Continent they are seen regularly in all the large markets, and command a ready sale. At the same time, the Egg Plant, as it is commonly called, is not at all a bad plant from a decorative point of view. I admit the large kinds are a little stiff, but the smaller and well-coloured fruits give variety. There are several kinds, but for use as a vegetable I prefer the black-fruited variety. It is useless to grow these plants in any quantity unless special care is taken in the cooking, as if cooked carelessly, much in the same way as our Vegetable Marrows, I would prefer the latter, which may be grown by anyone. These plants do well trained to a warm wall or covering a trellis, and during the past two summers I have seen them growing in the open merely supported by stakes. Anyone who succeeds in growing the large-fruited varieties of Capsicums would not fail with the Aubergines. Those who have not the best of soil or sheltered positions, or lack a warm wall, would do well to grow them under glass, a cold frame being suitable.

the form of top-dressing or liquid manure during growth. Unlike Tomatoes, they need little checking, as the fruit ceases to swell freely if the growth is unduly interfered with. For trellis-work the round Aubergine is specially suitable; also for frame culture, as it is not so heavy as the black variety; at the same time, I do not think the quality is so good. Another, and one of the best, is the New York Purple, the largest oval variety grown, and a very handsome fruit also. The Early Purple is somewhat similar, but earlier and smaller. There is also a reddish-coloured fruit called the Early Scarlet, but this is not so good as the black. The white bears a creamy-white, egg-shaped fruit, and is good for pot culture. There are other kinds with different coloured fruits, and some of the smaller ones are most ornamental grown as pot plants for house decoration.

Their culture is simple. Seed may be sown in pots or pans in a warm house in March or April, and when the seedlings are large enough they should be potted off into small pots singly or in boxes, the seedlings in this case being 3 inches apart. Later on they should be planted out in frames. If for planting at the foot of a wall, I would advise pot culture from the start and the use of a rich soil. A 6-inch pot will grow good-sized plants, and if large fruits are needed the fruit should be thinned when set, leaving three to five fruits on each plant. Liberal supplies of food should be given when the plants are growing freely, and ample moisture in the way of syringing all portions of the plants. Red spider is their worst enemy, and this should be kept down by frequent fumigation. The plants thrive well if well damped over in the evening after a hot day. My note does not concern the cooking, which is an important detail; but this portion I will describe on a future occasion should the editors of THE GARDEN think it would interest their readers. G. WYTHES.

BOOKS.

Home and Garden: Notes and Thoughts, Practical and Critical, of a Worker in both. By GERTRUDE JEKYLL. (London: Longmans). — It has been written, not inappropriately, of Miss Jekyll's new book that it is the "least commonplace of commonplace books." Much of it—perhaps the greater part does not come strictly within the purview of THE GARDEN, for the home is a gem set in the garden and a part of the harmony, and we hear much of the building of the home and of the manner in which it grew out of Miss Jekyll's ideas, hammered into shape by a clever and appreciative architect. Moreover, enough is shown of the home in the numerous illustrations, which are from photographs by Miss Jekyll herself, to leave the impression of a house unostentatious, but beautiful in no common measure. But it is not—or, at any rate, it does not aim to be—a show house, and it is evident from a gentle remonstrance in the preface that Miss Jekyll has suffered not a little from "kind and numerous, though frequently unknown, friends." Their visits have taken away from the time which she would have preferred to devote to the work which she loves, and the popularity of her book has clearly been a grievous hindrance to her in daily occupations. Personally, I know to my cost what this means. In the course of the day perhaps twenty persons call on me. Individually, each visit is a pleasure; collectively, they make work impossible.

Premising that all of this book which relates to the building of the house and to folk-lore concerning the names of plants, and to the grace of craftsmanship in him who uses common tools, is entirely delightful, let me go on to say that when it comes to a matter of gardening, the field covered by this book is necessarily narrow. Miss Jekyll has her general principles, which are applicable to all gardens, and she is not only a wonderfully keen observer, but also accurate and expressive, even rhythmical on occasion, in describing that which she sees and hears and smells, for her senses are very acute. But practical advice she will by no

FIG. 56. GABLE OF MR. WILL TAYLOR'S HOUSE, SHOWING CHASSELAS VINE, SOUTHERN EXPOSURE.

and studied the Syrian. I have four of them, but shall clear them out in favour of Moore's Early, Chasselas Rose, and some others more suitable to our climate.

The shape of these two Vines I take to be the best either on a wall or in vineyard rows. It is Clement Hoare's long-rod system produced according to his rules.

Another sketch shows the best open-air Grapes I have seen this year. The Vine is a Chasselas Rose,

VARIETIES.

I have already mentioned the value of the black-fruited kind, known as Black Pekin, the fruits being nearly black and long, not unlike a small long Marrow. The leaves are violet coloured, and even when not grown for its fruit the plant is most ornamental. This variety is one of the best for general culture on account of its free growth and cropping, but both this and several others of free growth need much food, which is best given in

means give save upon matters which he absolutely within her knowledge and her experience. Now her experience has been gained on what she calls "a poor soil," and it is true that on such a soil as she describes, grass-feeding plants—the better classes of H.P. Roses, for example—would certainly never grow to perfection. But the sunny hillside in Surrey, sandy although it be, is not a desperately poor soil. Birch and Pine and Heather and Bracken flourish on it in its natural state; also, there is a good sprinkling of peat in the sand, and there are many gardeners struggling with heavy clay who would be glad to have half Miss Jekyll's complaint. Still, it is rather poor stuff, and therefore the best soil in the world upon which to learn the two great secrets of successful cultivation. They are, firstly, to plant those things which are naturally best suited to the soil, and, of course, to plant them thoughtfully; and secondly, to feed them well and to make the fullest preparation for them. A dwindling, half-starved plant struggling against difficulties is no pleasure to anybody; careful selection among suitable varieties will give infinitely the best results. For tillers of poorish soils there is no better guide to be found than Miss Jekyll, but her list of plants for them is far from being long. Cisti of many kinds, Helianthemum, Lavender and Rosemary, Brooms, Spanish Gorse, Jerusalem Sage, Tree Lupines, American thornless Brambles, Rhododendrons and Azaleas (with careful preparation), Kalmias, auratum Lilies, Sea Hollies, Heaths, the blue-leaved Lyme Grass, Southernwood, Acanthus, Alstroemerias, the Mexican Orange Flower, Asphodels, Milleins, Cat-mint, Hyssop, Oriental Poppies (with deep working), Stobea purpurea, Gaultheria Shallon, Corchorus japonicus, the Tea Tree, Burnet-leaved Roses and Briars, Cluster Roses, and a few smaller plants are almost the whole tale; in fact, the struggle against Nature is severe, but the eternal principles of grouping remain the same always. I must not part from the volume without an expression of cordial admiration upon the eminently practical chapter on "Gardening for short tenancies," with special reference to Aldershot. This, even if it were published alone, would be invaluable to dwellers in that sandy desert.—J. E. V.

The Kew Bulletin. The last issue contains a list of books added to the library during 1898. A glance at this catalogue shows the comprehensive character of the library, embracing books as widely different as the "British Pharmacopœia" and Edith Jackson's "Annals of Eating from the Twelfth Century to the Present Time." Published by Eyre and Spottiswoode, East Harding Street, Fleet Street, E.C. Price 1d.

The Vicar's Wife, or the Great City. By EDWIN THOMAS. Wm. E. Richardson, Great Queen Street, W.C. A sad story in rhyme of the ruin of a widow and her two children through their betrayal by the tempting financial liveryment of a rich speculator. There is a feeling throughout of evangelical piety and tenderness.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

The next meeting of the Royal Horticultural Society will take place in the Drill Hall, James Street, Westminster, on Tuesday, February 13. The various committees will assemble at noon as usual, and at 3 o'clock the annual general meeting of the society will be held at the society's offices, 117, Victoria Street, Westminster S.W. The Council of the Royal Horticultural Society at its last meeting unanimously requested the president, Sir Trevor Lawrence, Bart, to allow himself to be appointed to the vacant Victoria medal of honour.

RICHMOND HORTICULTURAL SOCIETY AND THE LATE DUKE OF TECK.

At a meeting duly held on Thursday, the 1st inst. Mr. Thomas Skewes-Cox, M.P., chairman, in the chair, the following resolution was proposed by him, seconded by Sir Edward Hertford, K.C.B., and unanimously adopted:—That the Richmond Horticultural Society hereby places on record its deep regret at the loss which has befallen horticulture by the death of His Highness the Duke of Teck, G.C.B., G.C.V.O., a prince who for no less than 26 years past had been the president and valued friend and supporter of this society, and begs to tender sincere and respectful sympathy to their Royal Highnesses the Duke and Duchess of York and the other members of the late president's family in their heavy bereavement.

LINNEAN SOCIETY OF LONDON.

THERE will be an evening meeting on Thursday, February 13, at 8 p.m., when the following papers will be read:—"Photography of British Plants," by Mr. J. C. Shenstone;—"A New Land Planarian from the Pyrenees," by Dr. R. F. Schardt, F.Z.S.

MIDLAND CABINATION AND PICOTEE SOCIETY.

WE have received the ninth annual report of the above society. It contains the list of awards, the list of subscribers, and the balance-sheet for 1899, together with the schedule of prizes and rules for 1900. There is also a list of some of the leading flowers in each class suitable for exhibition. The last annual exhibition, held at the Botanic Gardens, Edgbaston, was again a great success; the Midland Counties' challenge cup was won by Mr. Robert Sydenham. The book contains an article on Carnation culture by the same eminent grower. The honorary secretary of the society is Mr. Herbert Smith, 22, Tenby Street North, Birmingham.

THE ROYAL GARDENERS' ORPHAN FUND.

THE executive committee met at the Horticultural Club on Friday, the 26th ult., Mr. William Marshall presiding. The secretary reported the receipt of the sum of £12 5s. from Mr. H. J. Jones, Lewisham, the proceeds of boxes in his Chrysanthemum houses, and it was also stated that it was the intention of the Richmond Horticultural Society, at their forthcoming show, to set apart a tent for the sale of flowers on behalf of the fund, a practice which may be heartily commended to the notice of other horticultural societies. It was announced that Lord Batterssea would preside at the annual festival of the fund, to take place at the Café Monaco on Tuesday, May 8. Messrs. P. E. Kay and T. W. Swales were elected to the vacancies on the committee caused by the death of Mr. A. Outram and the resignation of Mr. Thomas Peck. A financial statement of a generally satisfactory character was produced, showing that there is an increase of £74 1s. 6d. over the receipts of 1898, and a draft report of the committee was also submitted, both of which were approved for presentation at the annual general meeting on Friday, February 10, at the Essex Hall, Essex Street, Strand.

NATIONAL CHRYSANTHEMUM SOCIETY. ANNUAL MEETING.

THE annual meeting of the above society was held on Monday last at Carr's Restaurant, Strand, when Mr. Percy Waterer occupied the chair. The attendance was large, and the proceedings excited considerable interest. After the minutes of the previous annual meeting had been read and confirmed, the chairman moved the adoption of the report and annual balance sheet, with which he entirely concurred, excepting that he thought a special reference should be made to the generosity of Lord Rosbery in allowing the members to have their annual outing at Mentmore, an outing which he thought was one of the most interesting and enjoyable that they had ever had.

From the report we gather that the committee congratulate the society on the satisfactory condition of affairs. The shows for the past year appear to have maintained their high quality, the relations with provincial and foreign societies are as wide and firm as in the past, and the financial position is decidedly encouraging. Mention is made in the report of the success of the vase glass, which made an imposing display at the November Show, and also to the competition for the National trophy and the Holmes Memorial cups. The report also contains references to the proposed modifications in the privileges granted to affiliated societies, and to the deputation that visited the French N.C.S. show at Lyons.

The financial statement shows on the receipt side that £206 18s. 6d. was received for members' subscriptions, £151 6s. for donations and special prizes, £375 from the Royal Aquarium and various other items, bringing up the total to the year from all sources to £1093 0s. 5d. On the payment side it appears that the sum expended for prize money at the three shows amounted to £208 13s., medal account £112 5s. 2d., secretary's salary £100. Most of the other items are similar to those of previous years, and a balance of £76 18s. 6d. is shown to the credit of the society. This will enable the reserve fund to be increased.

After some discussion, in which Messrs. Simpson, Newell, Moorman, Dean, and others took part, the motion was carried. Then followed a vote of thanks to the auditors for their services in auditing the accounts. Mr. Cholmley and Mr. Beridge responded.

The election of officers for the present year then took place, with the following results:—President, Sir Edwin Saunders; chairman of executive committee, Mr. Percy Waterer; vice-chairman, Mr. Thos. Bevan; treasurer, Mr. C. E. Wilkins; foreign-corresponding secretary, Mr. Haman Payne. When the election of the general secretary was proposed, Mr. T. Bevan moved that it be postponed, and that advertisements be inserted in the gardening press for a secretary at a salary of £100 a year. This motion naturally caused a lively discussion, and in the end Mr. Richard Dean was again elected secretary by an overwhelming majority.

The next item on the agenda was the election of one-third of the executive committee, who retire annually according to rule. A large number of nominations was received, and the following gentlemen acted as scrutineers of the ballot, viz., Messrs. W. Seward, Crane, J. W. Wilkinson, and J. Burn. The successful members were Messrs. Witty, J. W. Moorman, Ingamells, Lyne, Newell, Sturrock, Cutbush, Cholmley, Holmes, Keene, Swales, Brooks, McLeod, Foster, and Dove.

Following this came the consideration of the report of the committee appointed to consider the relations of the affiliated societies with the parent society, and the secretary announced the names of several societies which had withdrawn in consequence. This seems to us rather premature

action on their part, as they could not possibly foresee whether the report would be carried in its entirety or not; and, as a matter of fact, the meeting was not in the humour to accept certain portions of that report. On the question of privilege I, as set forth in the printed copy of the proposed amendments, there was a strong consensus of opinion against the proposed alteration, and it was the subject of several amendments. In its final form it now stands as follows:—"To appoint one of its bona-fide subscribers as a delegate to the executive committee of the National Chrysanthemum Society, with power to speak and vote on any subject except finance."

The other proposed amendments passed without much opposition, and after a very busy evening the proceedings closed with a vote of thanks to the chairman for presiding.

ANSWERS TO CORRESPONDENTS.

Spawn on Water Lilies (E. W.). The only thing if ducks and sea-gulls are hatched, is to have plenty of fish in the water—golden and brown carp or perch. We do not suffer here, though we have lots of Bulini or water snails. The eadlis-worm does a little harm sometimes.

Quick growing climber (G. S.). The quickest growing climber of a permanent character is the Virginia Creeper, which makes rapid headway. Of evergreens there is nothing better than one of the strongest growing Ivies, such as Hedera dentata. Climbing Roses, Honeysuckles, and Clematis may be recommended if flowering plants are needed, while the more vigorous Tropæolums will, when raised from seed, soon clothe an arch. H. P.

Pot soil (JANE). If you wish to grow good plants in pots you must not mind taking trouble to get proper soil. The very best material for pot plants generally consists of two-thirds fairly decayed turf loam from a pasture, broken to pieces but not too fine, the other third being composed of well-decayed leaf soil and old hothed manure, all well mixed, and added to it a fair proportion of sharp white sand to help keep the compost open and porous. A very little guano or even soot sprinkled in with the soil helps to improve it. Generally the final potting of plants should be quite firm.

Syringing plants in greenhouse (F. KEEP). There can be no correct temperature given concerning the syringing of plants. You may damp down one day with safety if the weather be warm; whereas the next may be wet, dull, or foggy, and no moisture whatever is needed in the way of syringing. You must use judgment. In our variable climate, especially from November to March, syringing or damping down must be governed by the weather. In wet weather little or no moisture is needed in a greenhouse—by which we mean a house at 15° to 50° or lower at night. On the other hand, in fine weather with increased temperature one may damp down more freely. So much depends also upon the house, its aspect, the plants grown, whether flowering plants or Ferns. The latter need more moisture at this time. Very little overhead syringing is needed, none in damp weather, or say when the thermometer is under 45° to 50°, but in a house with few pipes, or not sufficiently heated, use more moisture on the floor to counteract overheating of the small heating surface. In all cases where plants are damped over they should be dry before dusk.

Double digging and trenching of soil (F. KEEP). Double digging is much the same as trenching. When the land is trenched, a wide trench is taken out and the soil wheeled to the portion of the quarter where the work finishes; at the same time the land is thrown into ridges. Of course, it may also be thrown up very roughly for the weather to sweeten; that is the reason trenching is done in autumn and the early winter. In trenching, the depth varies according to the nature of the subsoil; if the latter be poor, it is best left below, but may be dug or loosened. If a trench 3 feet wide and 2 feet deep be started, the soil is wheeled away at the start as advised above, the next space of 3 feet in width is marked off, and this is then dug in sections and 2 feet deep and turned over on the land from whence the soil was wheeled away. This goes on until the work is complete and the last 2 feet space is filled in with the first soil taken out, and in the digging of trenching one may either place in ridges say one, two, or more in the 3-foot space, or turn up as roughly as possible. Some good cultivators advocate removal of the bottom soil even when poor, and if this be of a friable nature, doubtless it is a good plan, but poor, inert soil means much labour and tool to bring it into good condition.

TRADE NOTES.

MR. HARBOURTY WEBB and MR. FRANK WEBB, sons of Colonel William G. Webb, of Wordsley, Stourbridge, who, after holding commissions in the 1st South Staffordshire Volunteer Battalion, recently joined the Imperial Yeomanry, embarked for South Africa on Saturday. Their many friends in the Stourbridge district abound in good wishes for them, and in the hope for their safe and early return.

THE GARDEN.

No. 1471.—Vol. LVII.]

[FEBRUARY 17, 1900.

A GARDEN CITY.

IT is commonly the fashion to greet any scheme of an utopian nature, if not with open derision, with at least a thinly-veiled expression of something nearly akin to it.

But those who will take the trouble to think for themselves cannot but perceive how immensely the embodiment of such a scheme as the one proposed by the Garden City Association would be to the benefit of numberless dwellers in our terribly crowded London, who might thereby escape its many dangers.

Every human organisation has somewhere a limit of possible expansion, and it is plain to see that in the undue growth of a densely populated area so vast as that of this immense city, many of its related groups of inhabitants swell into unmanageable masses that have lost all useful proportion to one another. Thus many of its units, to say nothing of its whole groups, are a hindrance instead of a help to the community, and, as a machine whose parts are not well balanced and fitted, there arises first friction, then breakage, and finally collapse, so in the over-grown and ill-balanced human aggregation will surely come in their appointed sequence poverty, misery, and vicious and criminal waste of life.

To get the people back upon the land, to enable them to lead lives that shall be clean and wholesome, profitable, and enjoyable, surely a scheme with such an intention deserves approval and encouragement: the more so that its initiators bring it forward, not in a spirit of sentiment only, but as one that must necessarily be worked out upon a sound financial basis. Their aim is thus set forth in their circular:—

"Much may be done to stop the depopulation of our agricultural districts by providing for the countryman the same opportunities of improvement as are so bounteously provided for his city comrade, by relieving to some extent the monotony of country life, and by providing better markets for his produce, and consequently rendering his labour more profitable. But can this be done? Let us see. Consideration of the remedy advocated by the Garden City Association for the complementary problem of overcrowding, which confronts our municipal authorities, may help us somewhat. This association recognises that there are many thousands of men and women who would gladly leave the noise and smoke of London if they could get work and congenial surroundings in the country, and suggests that when improve-

ment schemes and clearances of insanitary areas are being carried into effect, it would be in the highest interests of the city and of the country if, instead of rebuilding within the city, accommodation were provided for these people on estates, scientifically planned in the form of new cities at some distance away in the country where population is so much needed. If these proposals are carried into effect, the result would be the introduction of organised communities into sparsely populated districts, where countrymen would be brought into close touch with the life and vivacity of the city without severing their connection with the soil, and new markets would be opened up at their very doors. But have we any reason for believing such a proposal feasible? When we consider how cities have sprung up where special attractions have been provided by Nature or the enterprise of man, we need not, I think, despair of building one or more garden cities, considering that the attractions to be provided are comfortable homes, plentiful supplies of wholesome food, and opportunities for enjoying fresh air, the green fields, and running brooks. Now, how would such an estate affect the agricultural industry in the neighbourhood? Clearly, the prices for produce and the demand for labour would increase, and since the citizens would, many of them, bring their own employments, and would not enter into competition with those already on the land, a decided filip would be given to the condition of agriculturists, and a strong encouragement would be given them to remain in the country."

In a part of the prospectus is a diagram showing a portion of a proposed city plan of circular figure, with a large central space of public park or garden. From this some main streets radiate, cutting wider circumferences of habitable zones. This may be only intended as a slight preliminary idea, and we hope it may be so, as for many reasons a rectangular figure in laying out buildings is better. Nothing is so puzzling or bewildering as continued zonal progression, whereas a town that has at least its greater features laid out on a rectangular plan has its form and aspects presented in the simplest manner, instead of the most complicated; for by some such simple device as four main streets named North, East, West and South, approximately leading towards the cardinal points, a kind of key to the plan of the whole town is given, and the veriest stranger may at once know where he is. We also think it a grave error to surround any

town, as shown in the diagram, with a girdle of manufactories, for with such an arrangement the smoke of some of them must always be carried into the city.

Among many other advantages the deliberate planning of such a town would give an opportunity of providing the inhabitants with a very great, and in England unusual, advantage, namely, that of a daily market for perishable articles of food, thereby enabling the consumer to buy direct from the producer, and of buying the food materials in the freshest possible condition.

The thought of such a garden city makes one dream of all sorts of delightful possibilities, especially if the site might be partly of already matured woodland, so that the public park should be of well-grown trees to begin with, and so that in other portions of the city groups or groves of mature forest trees might be retained and worked into the plan.

THE ROYAL HORTICULTURAL SOCIETY.

THE excellent report of the society which was presented to the Fellows at the annual meeting on Tuesday last has already received attention in *THE GARDEN*, and it is needless, therefore, to enter at length into its special features. But we must congratulate the president, council, and secretary upon the great advance the society has made of late years, and the promise of even greater development in the future. No one present at the meeting on Tuesday could help thinking of the gatherings on other occasions when the society was emerging from its slough of despond, and throwing off the trammellings of a foolish and unfortunate policy. All that is past now, and the speech of Sir Trevor Lawrence, with remarks made by other speakers, show that henceforth the society will realise its power in the land for accomplishing great work for practical and scientific horticulture.

Allusion was made to several interesting developments of the future—one to a school of horticulture, and another the new experimental garden. A right note was struck when Sir Trevor Lawrence said that the Royal Horticultural Society should be the means of educating young men in horticulture, and considered that the County Councils might co-operate in the same good work. Chiswick has become a school of practical gardening, and the examinations held yearly under the auspices of the society have proved an unbounded success. The council in the future intend to foster every development which tends to elevate the calling of gardening. Of the new garden, which we are pleased to know is to be freehold property, more will be written in the future. Arrange-

ments are still in progress, and therefore little is known at present.

Many other interesting remarks were made concerning the society's future, which seems as hopeful as one could wish, and our account of the annual meeting will give details of the business conducted on this occasion. We have expressed before our hearty good wishes for the welfare of the society, now sailing into smooth waters, and whilst we thus express ourselves we are echoing, we feel assured, the desire of all who have horticulture at heart in this land.

RIVIERA NOTES.

THERE is a well-marked winter-flowering form of *Iris germanica* on the Riviera. It comes into bloom in December, and is a very great delight to northern eyes, recalling as it does in the shortest days the purple iris glory of May. I really do not know any flower that so cheats one into the belief it is full spring-tide just when the short Riviera winter begins. A good sheaf of these rich purple sprays and a handful of *Marechal Niel* buds from a south wall make, with Carnations, Violets and *Mignonette*, a summer glow in both garden and room, and cheer the wintry air whenever a few chill and dull days do come.

This season has been colder than any of late years, because the cold rains and dull skies prevailed for six weeks quite a trial to gardens and friends, though there has been no severe frost or special storms at Nice. Carnations of the *Mégatière* type are certainly the most hardy and useful. The large and lovely rose-shaded *Princesse Alice de Monaco* is especially a winter-blooming Carnation. Perhaps owing to its being persistently called "*Mahmaison*" by the florists I have never seen it in England. Its summer blooms are quite out of character and useless, so it may not succeed under glass in winter. Certainly give me the good old Tea Rose *Schablikine* as a model winter Rose; it is as hardy as *Safrano* and infinitely better, in my eyes; its fresh deep rose colour is so much clearer than *Papa Gontier*, that I wonder how many folk can grow only the latter.

To find the housemaid sweeping the parquet floors with half-withered, sweet-scented *Geranium* leaves is a luxury appreciated by a sensitive nose, which recalls the stuffy smell of the familiar tea-leaf, so dear to English households, only to enjoy the more this fresh fragrance, especially if the morning sun be as bright as it should be.

How many subtle memories hang around some such sweet odour! To me a bunch of Parma Violets, surrounded by sweet *Geranium* leaves, is the most delightful scent I know, just because I first enjoyed it that sunny February day long ago, when kind old friends welcomed an invalid to these sunny shores, fresh from the fogs of Oxford. E. H. WOODALL.

Orchids were the only plants given certificates or awards of merit at the meeting of the Royal Horticultural Society on Tuesday.

SIR TREVOR LAWRENCE, Bart.

A PORTRAIT of Sir Trevor Lawrence, Bart., will interest our readers at this time, when the Royal Horticultural Society, of which he is president, is forming itself into an organisation stronger and more enterprising than during any period of its history. Sir Trevor is a keen gardener, and in his beautiful garden at Burford, Dorking, nestling at the foot of Box Hill, rare plants of all kinds, and Orchids in particular, are extensively grown. It is unnecessary to write more on this occasion. Sir Trevor Lawrence's name is well known wherever gardening is devotedly followed, and it is satisfactory to know that his name is now enrolled amongst the Victoria medalists.

SIR TREVOR LAWRENCE, BART.

(President of the Royal Horticultural Society.)

NEW AND RARE PLANTS.

LELIO-CATTELEYA BERTHE Fournier var. SLENDIDA.

THIS is a distinct and desirable hybrid, superior to the flowers certificated, from the late Major Mason's interesting collection, in August last. It is derived from the intercrossing of *Laelio-cattleya elegans* and *Cattleya Dowiana aurea*. With regard to the growth and shape of the flowers, it resembles the parents. The sepals and petals are of fine form and substance, the sepals 4 inches long

and deep rosy lilac, whilst the petals are deeper in colour, equal in length to the sepals, and 2 inches across. The finely-shaped lip is 2 inches broad, the whole of the front lobe deep crimson-purple, veined with a darker shade of colour. The side lobes are also crimson-purple, becoming lighter towards the base, where they are thickly covered with prominent yellow lines, as seen in the *C. Dowiana* parent. The plant carried a two-flowered raceme. It was awarded a first-class certificate at the Royal Horticultural Society's meeting, February 13 last. Exhibited and raised by M. Chas. Maron, Brunoy, France.

ODONTOGLOSSUM CRISPUM MUNDAYANUM.

This is one of the finest of the spotted forms of *O. crispum*. The flowers are each about $3\frac{1}{2}$ inches in diameter, with the segments of an even form. The sepals are each about 1 inch wide, white inside, with purple colouring on the exterior, and so reflected through that it gives the appearance of a rose suffusion on the interior. The whole of the central and basal areas are thickly covered with rich purple blotches. The petals are upwards of 1 inch broad, much fringed on the margins, white, suffused, as in the sepals, with rose. There is a large oval-shaped blotch of purple 1 inch long on the basal portions. The lip is upwards of 1 inch broad, white, with a large blotch of brown running down the centre, and numerous smaller brown spottings surrounding and on the yellow disc. A cut raceme of two flowers came from the collection of Mr. N. Cookson, Oakwood, Wylam-on-Tyne.

ROSE GARDEN.

HARDINESS OF TEA ROSES.

ONE mode is to work all our best and most fragrant Roses on the seedling Briar or Dog Rose. Thousands of Rose growers have such faith in the cure for tenderness and sterility of bloom, that they will grow no Roses of any sort, unless it be a few summer or climbing Roses, unless they be mounted on a strong seedling Dog Rose stock. So far, those who hold such views have at least the courage of their convictions, and are growing Tea Roses on an enormous area, and laid out for budding in lines many miles long.

To do the dog "rosarists" justice, it should in fairness be stated that the seedling "briarists" were often at bitter variance with those who preferred Briar cuttings, or suckers, or layers. So far the Dog Rose "argumentists" have the best of the argument and the run of the practice. The only rival stock in the Rose trade to-day that really competes in numbers, &c., are Dog Rose seedlings and the Briar cuttings, the same species, though the stocks are by no means identical.

There are differences in regard to the number, character and place of the roots between seedling and cutting Briar stock. Cuttings produce more and smaller roots and distribute them nearer to the surface than seedlings. The latter have fewer, larger, and more vertical roots than Briar cuttings. Of course these natural diversities may be modified by root pruning or other culture, but on a large scale this is seldom done. And if it were, both the seedling and the cutting Dog Rose develop a

strong tendency to revert to their natural modes of rooting.

EFFECT OF DEEP OR SHALLOW ROOTING AS TO THE HARDINESS OR TENDERNESS OF ROSES.—It is pretty certain that as many Roses are crippled and killed through their roots as through their tops. One more point should be noted here. The relation between the scion and stocks of Roses is not wholly one-sided. Each acts and re-acts on the other. The Dog Rose supplies all the food and blooming wants of the charming Tea Rose mounted on its crown. But in this new mission of nurturing the superior Rose, some, it may be much, of the original vigour of our native wild Dog Rose is tamed down into the moulding of our loveliest garden Roses into new forms, or painting them with richer beauty. If this be so—and it is—it may surely be also possible for Tea and other Roses to be made more hardy as well as stronger for their mount on the Dog Rose. This much is certain, that most of the successful growers of Tea Roses in Scotland grow their Teas on the Dog Rose stock, which may have proved a factor in their growing hardiness. In one rosetry alone, the Dalhousie Nursery, Broughty Ferry, Dundee, some four miles of beds 4 feet wide are annually sown with *Rosa canina* to supply their wants and those of their customers.

OWN-ROOT TEA AND OTHER ROSES.—Whatever weight should be attributed to these views as to seedling stocks of Dog Roses making the Roses grown on them approximate in absolute hardiness to the Dog Rose, the wider and longer one's experience in growing or showing Roses, the more one favours the more natural plan of growing all Roses on their own roots. Once this more rational plan is adopted, there will be found but little waste of time or material involved in the change. It has been said that it takes some five or six Rose buds to make a good cutting. But this objection to own-root Roses ignores the fact that Rose buds may be rooted in damp sand, soil, or Jadoo fibre almost as soon and as surely as in the growing tissues or sap of the Dog Briar Rose. The newly-rooted Briars may lose a day or two for lack of the nurturing sap of the Briar, but by surrounding it with genial conditions and potting in rich fostering soil, or a half-and-half of soil and manure or leaf-mould, the sand or soil-rooted bud may be stimulated to grow almost abreast of the Rose eye budded on the Dog Rose. In the case of the cutting, the gain in size and time of the plants goes far to compensate for the loss in individual buds. But as own-root Roses get more popular, Rose cuttings will become smaller.

SUCKERS.—These will more than compensate growers for any losses, real or imaginary, through the changes of fashion in the propagation of Tea and other Roses. A strong prejudice has sprung up against suckers, for the simple reason that such were in nine cases out of ten the shoots of wilding Briar or Dog Roses. But if every Tea or other Rose sucker is already a rooted Rose plant, the feeling against them would soon die out, and good suckers be gladly welcomed in all Rose beds, borders, groups in grass, in park, home shrubberies, plantations, &c.

OWN-ROOT ROSES OF EQUAL AND THE SAME HARDINESS THROUGHOUT. This is an immense advantage. We have noted the disease and death among Roses in many counties. Three-fourths or more among them have occurred at the point of union between the scion and stock, this through rooting Roses from buds or cuttings directly in the soil, and the main cause of disease and death vanishes with the budding and grafting.

THE DEEPER PLANTING OF OWN-ROOT ROSES AN EASY PLAN OF PROTECTING THEM FROM EXCESSIVE COLD.—There are few protectors so potent as 2 inches or 3 inches of soil round the root-stock or collars of Roses through exceptionally severe weather. Keep the soil over the roots round the collars of the Roses loose through frequent scarification or hoeing, and the layer of loose earth becomes practically impervious to the loss of terrestrial heat.

ALL THINGS POSSIBLE TO A ROSE BUSH OR TREL WITH A SOUND COLLAR AND HEALTHY ROOTS. Such Rose bushes of uniform quality throughout possess all the elements of safety and reproduction

within themselves. Zero frosts may cut them down to the ground level with stern severity, and yet do them little or no injury. Such mischief concentrates rather than exhausts the marvellous resources and capacities of Rose life and growth.

JACK FROST AS A PRUNER OF OUR ROSES.—Dean Hole was one of the first to tell rosarians to put their love into their Roses if they expected to gather perfect blooms. Jack's hand is chilly cold and his sharp frost-bite deep and cruel. When Jack is abroad on sharp, clear nights stealing the heat of our Roses from bank to sky, or flying throughout our Rose gardens on piercing March winds, he is the harshest, hardest Rose pruner in the world. With their collars and roots safe, their recuperative powers are beyond Jack's icy grip. The latter has furnished lessons in pruning for many modern growers. Yes, we prune Roses hard in love as well as in ignorance. By shaving off the tops of own-root Roses close to the ground-line in November or March or a little earlier or later, according to locality, we may augment the vitality and store up the resources of our Roses for a double or continuous harvest of beauty throughout the coming summer and autumn.

THE ROSE AS A HERBACEOUS PLANT.—We all know it as a deciduous or semi-green shrub. Assuming for a moment that last year's flowering stems and branches died down every year like a Delphinium, a herbaceous Peony, a tall Phlox, &c., should our double or manifold harvests of Rose bloom suffer loss or gain in number and beauty in consequence? Many years' experience forces one to the conclusion that such an entire change of habit and constitution among our Rose bushes would give us more and fresher blooms for a longer period.

TREATING THE BLOOMING PORTION OF ROSE WOOD AS ANNUALS.—The first result of hard or close pruning is a forest of shoots coming forth with the breath of spring. Supposing dwarf Tea or other Roses planted from 15 inches to 18 inches square, from three to five shoots would be sufficient to leave on each plant. The thinning of shoots should be done in April or May, after which the shoots will soon show flower. If the Roses are for show, disbud to the best bloom on each shoot, though the Roses look so much better if all the flowers that show are left; disbud the shoot 6 inches or 9 inches below the selected bloom, after cutting the first crops of blooms about 9 inches or 1 foot below the first flowers. The shoots under this concentrated mode of culture speedily break again into a second, or even third, harvest of blossom, as such concentrated culture and fairly liberal feeding and a loose surface flood of Roses with the renewed beauty and vigour of youth every year.

TWO STRINGS TO OUR BOW FOR HASTENING AND HEIGHTENING THE FLORIFEROUSNESS AND HARDINESS OF OUR ROSES. My second string runs in quite the opposite direction. Give Tea Roses their heads, and let them run up trees or scramble over houses, buildings, rocks, and enjoy and gather Roses when you may. The only pruning needed may be removal of exhausted shoots and the training out of killing crushes among the branches. There is plenty of room for these opposite systems of growing Roses in most gardens, and few of us can recall any garden that was over-rosed unless those of a few exhibitors who had strowed them into something like bullock-sheds. D. T. FISH.

TEA ROSES AND THEIR HARDINESS.

WHILE I do not profess any special knowledge of Roses, I may be allowed to remark that the different views expressed on this subject by your correspondents are not incompatible with each other. I have gone rather carefully into the question of the hardiness of the Tea Rose in Scotland, and have formed the opinion that the views taken by Mr. D. T. Fish are practically correct so far as they apply to the greater part of that portion of the kingdom Mr. Fish's knowledge of the Rose and its ways is wide enough to enable him to speak with some confidence upon it so far as regards a great part of England, and I confess to being surprised that Mr. Grahame does not seem to be

acquainted with him, by reputation at least. I have not had the pleasure of meeting Mr. Fish in person, but I know his work in the field of gardening literature.

I entirely agree with what he says regarding the hardiness of the Tea Rose in the east and north-east of Scotland. Those who have seen it in the Aberdeen nurseries cannot but express their concurrence with Mr. Fish in his references to this Rose as grown there. I may add that when I had the pleasure of visiting the Royal Gardens at Balmoral in 1897, Mr. J. M. Tromp, Her Majesty's gardener, told me that he thought the Tea Roses were fully hardier there than the Hybrid Perpetuals. I remember that I asked particularly if the Teas were hardy there. I have a note of some of the Roses, but as I made no inquiry as to which varieties were the hardiest, I will not venture to name any. I think that a Rose which stands the severity of the climate of that part of Deeside can hardly be considered tender in the ordinary sense of the word.

Yet, I think that there are some parts of Scotland where it needs some care. In close, sheltered gardens where there is not a free circulation of air it does not thrive so well, and I know some gardens which, to all appearance, are much more favourably situated and are in the south-west, where many plants are lost. I would not like to commit myself to the bare proposition that the Tea Rose is hardy everywhere in the United Kingdom, but I go the length of saying that it is much hardier than is generally supposed. S. ARNOTT.

Carschoorn, by Dumfriess, N.B.

GARDENING OF THE WEEK.

KITCHEN GARDEN.

GENERAL WORK.

THE heavy fall of snow in the southern part of the country will have put a stop to digging, manuring, and such work; on the other hand, it will have preserved tender growth of such plants as Lettuce, Endive, and the small spring Cabbages, the snow protecting from the cold north-east winds. During such weather other work may be taken in hand that will save time at the busy season. Pea and Bean stakes may be prepared and tied in bundles for use when required; labels may be prepared, also manures turned and soils mixed, and rubbish charred to wheel on the ground when required. Advantage should also be taken to note any defective drainage and remedy the same at an early opportunity.

FORCING DEPARTMENT.

There will now be more demand than formerly. Seakale should be introduced into its forcing quarters in quantities, according to the demand, every three weeks or oftener. The same applies to Rhubarb, as it is of much better quality when not forced too hard at the start. Asparagus will need to be grown near the light to get the growth nicely greened. Roots placed in a frame with a temperature of 60°, with 15° to 20° more at the roots, will give good shoots for cutting for three or four weeks. Fresh material should be placed in heat at least every three weeks to keep up a regular supply. French Beans may now be sown, and with a certainty of a fair return if the grower can give a liberal temperature, say 65° to 70° at night, with a rise by day. Larger pots may now be used

7-inch or 8-inch and the soil should be of fairly light character with ample drainage. I like to fill the pots to within 2 inches of the rim, as I find the top dressings needed are best given in the shape of fertilisers or liquid manure. Avoid overcrowding; five plants are ample in an 8-inch pot and little moisture is needed till the plant shows well above the soil. Cucumbers should now be growing freely. Maintain a genial temperature of at least 65° at night and 40° more by day, and afford ample moisture in all parts of the house, syringing three

or four times daily; also cover the glass at night-tall to avoid having to overheat the hot-water pipes. It is well to fruit sparingly at the start, so that the plants continue to strengthen. As growth increases feed freely and top-dress the roots every fortnight with good loamy soil mixed with a little bone-meal or Thompson's manure.

TOMATOES.

Seed sown early in the year will now be large enough to pot off, and few things need more careful handling. The seedlings are best potted up in the house where they are growing, and a rich but light soil employed at this stage, placing the plants near the light and in a genial temperature till new root growth is made. Plants sown last autumn may now be planted out in their fruiting quarters or potted on. The latter is advised to get early fruit, but the quantity does not equal that borne on those planted out. Seed may now be sown for what is termed the main crop supply from July to September, and also for plants for the open ground, but these latter when once the roots reach the sides of the pots after their first shift—should be grown near the glass in frames to prevent drawing, and, failing frame room, I would defer sowing for three weeks. For open-air fruit our best Tomato last year was Sutton's Earliest of All, and the Conference, though not large, is a splendid cropper grown thus.

FRAME VEGETABLES.

Under this heading must be mentioned such useful roots as Carrots, Turnips, and Radishes. The last need so few cultural directions that I will take them first, and here let me advise giving them a separate space, as I find that when sown to precede Carrots they do that crop much harm. There is no lack of forcing varieties of Radishes, Sutton's Earliest of All will mature in four or five weeks after the seeds have germinated, and having such a very small leaf growth may be grown much closer than others. Crimson and Carmine Forcing are both excellent; also the French Breakfast, one of the best of this type. No matter what variety is grown, it is well to have a little bottom-heat at this season of the year, as growth is then much quicker. We use manure and leaves mixed, but with hot-water pipes as the heating agency beware of dryness of soil. This is fatal to good quality, and the temperature of the pit or frame should not exceed 60° in cold weather, with ample ventilation on all favourable occasions. G. WYTHES.

FRUIT GARDEN.

MELONS.

As soon as plants raised from seed sown during last month have attained a suitable size for planting, let it be done. They are sun and heat-loving plants; therefore the house in which to plant them, if the best results are to be obtained, must receive full benefit from the sun and be well provided with hot-water piping. Bottom heat from hot-water pipes is essential, or well-sweetened hotbed material, such as leaves and stable manure. I always think the fruit is of better flavour when grown over the latter. Suitable soil is heavy loam, cut from pasture land 4 inches to 6 inches in thickness, freshly cut, or which has been previously stacked for a time. I have used both many times, but cannot say which is the more suitable. By using it freshly cut, the labour of carting from the soil heap is saved.

Soil to the depth of 6 inches is sufficient if placed on a hotbed, but if on timber or flat stones over a dry hot-air chamber, 8 inches or 9 inches is more suitable to their requirements. The soil when being made up should be moderately moist, and made as firm as possible. Let two days intervene between getting in the soil and planting, so as to give the bed time to warm. Suitable distances to plant are 3 feet apart and with two rows of plants opposite each other. If the length of latter is 6 feet and upwards, plant on small hillocks, leaving the seed leaves about 1 inch free above. Place a stick to each plant, with one end in the soil and the other tied to the trellis; let there be not less than 1 foot of space between the trellis and glass, whether formed of strained wire, or portable hurdles made of 1 inch flat iron and $\frac{1}{2}$ inch rod iron. The latter

system is convenient when all the head room possible is required for plants after the Melons are ripe. After planting give an application of tepid water and a loose tie of raffia to each plant. Suitable temperatures are from 65° to 70° by night, 75° in the day from fire-heat, with a rise of 10° to 15° from the sun. Maintain a sweet growing atmosphere, not too humid, by damping all surfaces by the syringe early in the afternoon during fine days. In the early stages not much ventilation will be required, and none at all if the temperature is not likely to exceed 90°; as the season advances more will be required, when the first chink may be put on at 80° at the apex of the house.

Sow seeds for a successional crop, and use 5-inch pots filled to within 1 inch of the top with sifted loam. Scatter eight to ten seeds in each, cover with soil to the depth of $\frac{1}{2}$ inch, afford water through a rose, and protect with a piece of glass to keep away mice. A light position in the Melon or Cucumber house is suitable for them. Pot off after the formation of the first natural leaf.

CUCUMBERS.

Plant the earliest seedlings and sow more seed if a further supply be desired. The soil must be light and open and made up of three parts loam to one of old Mushroom bed manure. If the latter is not at command, use horse droppings, sweetened previously by lying in a shed and being occasionally turned. Half a bushel of soil is ample for each plant at the time of planting, to be added to afterwards in small quantities as often as it becomes permeated with roots; water liberally throughout the season from the time the roots have taken hold of the soil, and maintain a moist atmosphere by syringing once or twice daily. The temperatures given for Melons are amenable to Cucumbers.

PROPAGATING VINES.

Put in eyes if not already done of varieties according to requirements. If for forcing, Black Hamburgh is still the best, and Foster's Seedling the most satisfactory. The best eyes are those from the base of side shoot prunings. Prepare them by cutting the wood through 1 inch below the eye and $\frac{1}{2}$ inch above, insert them down to the eye in loam pressed firmly into 3-inch pots, plunge these in bottom-heat in the Melon or Cucumber house, and water as often afterwards as the soil shows signs of dryness. G. NORMAN.

The Gardens, Hatfield House, Herts.

INDOOR GARDEN.

GLOXINIAS AND ACHIMENES.

EARLY batches may now be started, and seeds of the former may be sown, dealing with the seeds in the way recommended in a former note for Streptocarpus and Saintpaulias. Achimenes lend themselves readily to treatment under which they flower in successional batches, so that to cover a long season we may commence now with a portion of the tubers, dealing with the remainder at intervals up to the end of April. It is best to start the tubers, after shaking them free from the old soil, in boxes or pans, in which they may be inserted thickly in light sandy soil, transferring them to the pots or baskets in which they are to be flowered after they have made a couple of inches of growth. Water must be cautiously used to commence with, gradually increasing the supply after growth begins. The soil for final potting should be equal portions of peat, leaf-mould, and sandy loam, adding sand and decayed cow manure freely. From the start until the plants begin to flower they should be grown in a stove temperature; afterwards, cooler and more airy structures suit them very well. Gloxinias, too, may be grown in successional batches, but are never seen in better condition than they reach after being started just about this season, as when the tubers are kept dormant till late they appear to lose something of their vitality, so that it is best to raise seedlings for late work. A compost similar to that for the Achimenes is suitable for these plants, and a heavy sprinkling of silver sand should enclose the tuber, which may be potted with its crown just a little way beneath the surface soil. Use the soil in a fairly moist state, and avoid giving more water until growth begins. Look out sharply from the first

for the tiny thrips which plague these and nearly allied plants, for they mean ruin to any plant on which they are allowed to develop. Keep the house at about 65° at night, and syringe freely with tepid water on the surface and round the pots.

CUTTINGS.

of various stove plants, Crotons, Dracaenas, Panax Victoria, Acalyphas, and the like, may now be put in, as they will strike readily in the propagating boxes, which should at this time of the year be kept filled with young stock to replace leggy and worn-out specimens. Dracaenas of many varieties may be easily raised from "toes" or from stem cuttings, these being made from plants that can be spared. Crotons of strong growth can be best raised by "ringing" the tops and mossing them up till roots form in the moss. This method is especially suited for those varieties with very long leaves, as these are difficult to place in narrow quarters without injury.

REPOTTING PALMS.

Those which require potting had better now be overhauled, but it will be found in many cases unnecessary to give the plants a larger-sized pot, for really good plants may be grown in quite small receptacles if they are well treated in other ways, and they are so much more useful for house work when the pots are small. It is often found that Palms grown in pots larger than their needs demand get into a sickly state from the soil becoming sour. Fibrous peat and fibrous loam in equal proportions and mixed freely with sand form a good compost for most Palms; the pots should be well drained, so that water may be given freely without injury, and the roots should be as little as possible cut or broken in repotting. J. C. TALLACK.

Shipley Hall Gardens, Derby.

PUBLIC PARKS.

ACREAGE OF SOME LONDON PARKS AND RECREATION GROUNDS.

AT a recent meeting of the Ealing Gardeners' Society, Mr. Gingell read a paper upon "Parks and Gardens," and gave the following interesting statistics. Speaking of London, he said: Boston has a common, and Chicago has two fine parks in their centres, but there is no other town on either side of the ocean which can show such a list of public open spaces entirely surrounded with houses, and over ten acres in extent, equal in number and in size to that of the following parks and gardens situated within our own metropolis:

	ACRES.		ACRES.
Battersea Park	198	London Fields	26
Blackheath	267	Meath Gardens	11
Bishops Park	17	Myatt's Gardens	14
Clapham Common	229	Paddington Recreation Ground	25
Clissold Park	53	Peckham Rye and Park	113
Deptford Park	12	Ravenscourt Park	34
Dulwich Park	72	Regent's Park	473
Finchley Park	115	South Hackney Common	29
Greenwich Park	185	Southwark Park	63
Green Park	54	St. James's Park	93
Hackney Downs	41	Thames Embankment Gardens	14
Highbury Park	27	Victoria Park	244
Hilly Fields	43	Waterloo Park	30
Hyde Park	351		
Kensington Park	19		
Kensington Gardens	275		

Those in the following list are partly surrounded by houses:—

	ACRES.		ACRES.
Acton Green	12	Ladywell Recreation Ground	47
Acton Recreation Ground	25	Maryon Park	12
Back Common	12	North Mill Field	23
Barnes Common	100	Petersham Park	111
Bostal Heath and Woods	111	Plumstead Common	190
Brookfield Park	78	Richmond Green	10
Bushy Park	994	Richmond Park	2358
Ealing Common and Green	50	Royal Victoria Gardens	10
Ealing Lammas Lands	25	South Mill Field	26
Eel Brook Common	11	Streatham Common	66
Epping Forest	5348	Sydenham Recreation Ground	17
Hackney Marshes	335	Tooting Beck and Grave-ney Common	207
Hampstead Heath	595	Wandsworth Common	183
Hampton Court Park	752	West Ham Park	80
Highgate Woods	79	Wimbledon Common	1412
Kew Gardens	246	Wormwood Scrubs	193
Kew Green	11		
Kilburn Park	20		

(Approximately 17,000 acres.)

WALL GARDENS. II.

THE beauty that the Divine Artist bestows with so lavish a hand upon the world may, in some lesser measure, be reproduced by man about his own dwelling-place. Instead of naked, blinding walls, why not cultivate rock plants so as to mitigate the displeasing bareness of the stone, and why not, in the many cases where it might be done, do away with the barren look by having flowers and foliage? Architects will tell you that it is prejudicial to the well-being of the walls, a statement which admits of some doubt. But in any case, even admitting this to be a fact, is it not better to put up with a little injury in this direction in order to gain an abundance of wholesome joy of mind and eye?

I remember to this day how deep an impression I received from the sight of an artificial rock wall covered with plants and flowers in M. Edmond Boissier's far-famed botanic garden at Vullyres-sous-Rance (*Suisse Romande*). I was then only ten or twelve years of age, but my mind retains the remembrance of that flowery wall as clearly imaged as on the day when I first saw and admired it, with its large rosettes of *Saxifraga longifolia* more than 10 inches across, and its tufts of *Haberlea* from Mount Rhodope.

It was, and still is, a wonder, for the plants have survived their illustrious collector. And yet how little has the example of this immortal botanist been followed, for, except in the case of some veteran plant growers and of the few people who love what is beautiful and pictorial, there are but a small number who care for old walls enlivened with flowering plants. Alphonse Karr, at St. Raphael, preached in vain by his writings and by his example; there were none to understand his teaching. Still, during the last few years the taste for alpine and rock plants has spread, the ornamentation of rough walls has begun, and the importance of this way of gardening is now acknowledged. We learn from Nature that there is a whole range of species that actually prefer to be placed vertically in rockwork, the better to thrust in their roots, and there are even some that will only live and thrive in such conditions.

One often wonders how these pretty plants can live, that drive their roots deep into the clefts of the barren rocks without an atom of soil or humus for their organic structure to feed upon. To account for this one must learn something about the part that stones have to play in Nature's economy, for it is one of the largest and most important. All stone, hard or soft, or of whatever nature it may be, is porous and absorbs water by capillary attraction. The rock acts exactly as does the lump of sugar when one of its surfaces touches water and it fills itself with the liquid. During the seasons of rain or fog or damp the rocks act as sponges and absorb water by their sides till they are completely saturated; the more porous the rock, the more quickly is the absorption effected. The structure of the stone comprises a quantity, more or less numerous, of minute fissures that mineralogists know as *diachuses*. They are formed imperceptibly under the influence of frost and thaw in the very heart of the hardest stones, producing in them important effects as much from the point of view of the disintegration of mountains as of that of their property of sucking in water, in order to give it out again at the foot of the rocky masses. These *diachuses* constitute so many canals, which conduct and carry off the water which is absorbed by the innumerable pores which compose the internal texture of the stone; they are larger and more numerous in calcareous rocks than in granitic, which accounts

for the fact that limestone vegetation is more interesting and varied than that of granite. Now, these rocks soaked with water are reservoirs of coolness and moisture that Nature uses with due circumspection for watering and irrigation. Copious waters often spout from the heart of the most arid rocks, and it is at the foot of the mountain whose craggy head is wholly barren that the richest springs are found. It is also in the heaps of *Schists*, the barren-looking *lappin*; that the most delicate

Thus we see that in Nature a rock-mass plays the part of a sponge; it absorbs superabundant moisture and gives it off to the atmosphere or to the roots of plants—often, indeed, to the atmosphere through the medium of the rock-loving plants, and just as the need makes itself felt. This is the reason why so many delicate plants succeed perfectly when we grow them in rocky crevices, whereas if we tried to cultivate them otherwise they would be burnt up by the rays of the sun.

WALL PLANTS IN THE JARDIN D'ACCLIMATION, GENEVA. VELLA SPINOSA, SAXIFRAGA LONGIFOLIA, EBENUS, PHYTEUMA COSMOSUM, ETC.

and often the most brilliant flora is displayed. The roots ramble far through the heaped-up pebbles or into the deepest fissures in search of the coolness and life that they communicate to the organs spread out upon the surface. That surface itself gives off a constant vapour which surrounds the tender foliage and the dainty corollas, protecting them with a delicate veil from the sun's scorching rays. It is also this that allows the tender Fern fronds to spread over the rocks in full sunshine, for it is well known how much these plants fear exposure to dry air.

This being so, it shows how much interest is attached to the cultivation of plants in walls, for not only are they delightfully pictorial when so placed, but it also allows us to grow a whole range of delicate plants that are certain to die if they are given a position vertical with their axis (horizontal with their surface), on account of decay, brought about by water stagnating among their crowded branches and favouring harmful parasitical growths. Some walls so covered with flowering plants form true botanical gardens—won-

drons, ever changing pictures that one examines and admires with even more enthusiasm than those of the greatest artists, for they are painted by the Great Artist Himself, the Master whose work is above all others.

Now the means whereby these delightful results may be obtained is within the reach of all. It is only needful to secure that the wall shall be thick enough to allow the moisture to condense within it. The retaining walls are the best, because the soil that is supported by one of their sides stores a constant supply of moisture in immediate contact with them. In such a wall you have only to make a little opening, unless you find one ready, and to introduce the roots of your plant, and to fix it in position with a little Moss or Sphagnum, or a little rather stiff mould; then you make it all firm by means of a few small angular stones that you can even secure with cement if it should seem desirable. Often it does quite well to sow the seeds of such plants as are easily raised from seed, such as *Erimus*, *Linaria alpina*, &c.; these you introduce into the fissures by means of some rather stiff soil with which the seeds have been incorporated. In a very few years you will have a wall so superbly bellflowered, that it will draw enthusiastic expressions of admiration both from yourself and from your friends. In our own case it is a simple greenhouse wall that has been furnished, both inside and out, with an abundant variety of rock plants.

The views of the wall, kindly taken by Miss Willmott, give a good idea of it. We grow in it a number of delicate things: *Androsace imbricata*, *helvetica*, and *pyrenaica*, *Antirrhinum glutinosum* and *sempervirens*, many *Primulas* from the Tyrol, *Edraianthus*, *Jankaea Hel-dreichi*, *Haberlea*, *Vella spinosa*, *Campyloclatone excisa*, *clatinoides*, *car-niola*, *Ra'neri*, *ceusis*, *Zoysi*, *mirabilis*, *serotina*; *Scelopendrium Hemionitis*, &c. It is a delightful manner of making use of old walls, and the only way of cultivating a certain number of difficult plants.

Geneva. H. CORREVOX.

COLD WEATHER NOTES.

FIRES IN THE FROST.

It is always satisfactory when one has to light a fire in order to get rid of those aggregations of dead roots and rubbish which seem for ever accumulating in all gardens. It is an excuse for a bonfire, for which I retain the most childish affection, and which never seems to wear a more familiarly endearing aspect than upon the afternoon of a winter's day. The sharp smell of burning stuff; the red eye of flame in the heap; the smoke rolling slowly and heavily away; the sudden crackling of a dry stick resounding in the frosty air—all these bring with them trains of association, which have been accumulating much longer, I suspect, than the course of any one single lifetime. Reminiscence, who can tell, of that remote day when the human hearth was for the most part not an indoor, but an outdoor one.

A friend of mine has improved upon such casual burnings by having what may be called a permanent bonfire in her grounds, and I wonder more people, who love their gardens, and spend whole winters in the country, do not adopt the plan. That in one respect it is an inferior bonfire I am free to admit, for its main constituents are not leaves and sticks, but

anthracite coal. To make amends, it burns away merrily night and day, only needing to be replenished, I am assured, once in twenty-four hours. Her garden lies in the very middle of a big Pine wood, and the fire has its home in an open lodge, a *gazebo*, supported by Larch poles, without door or window, but made possible to sit in in cold weather, by being match-boarded on three sides, the south one alone being widely open. Until one has actually tried, it is difficult to believe how comfortable one can be in such a spot even on a very frosty evening; both feet extended to the blaze, and a rug tucked round to keep off stray draughts. As daylight wanes the red glow increases, lighting up the big Pine trunks, and awakening in one's mind vagrant suggestions of camp fires and forest settlements,

produced by any really strong atmospheric variation. Crackling grass and glittering ice-bound trees awaken one set of suggestions. Roaring winds, a drenched earth, and inky clouds tumbling wildly over the sky, arouse quite others. Even things inside the garden, plants that have been perhaps put there by one's own hands; clumps, say, of Bamboos and reedy grasses, *Arundo donax* and the like, assume suddenly new and slightly savage aspects when one sees them sweeping to and fro, or buckling like so many fishing-rods under the lash of a sudden tempest. The commonplace is not absolutely unescapeable, though it often seems as if it were. There are wider, freer notes, which only need awakening to stir and thrill us with their presence. The imagination leaps to meet them, and feels them to be its right. For we are all heirs to a large inheritance, though we are apt, as a rule, to be forgetful of the fact.

EMILY LAWLESS.

"IN A SMALL WAY."

NOTES FROM AN OBLONG GARDEN.

ONE of those delectable gardens, enclosing a large acreage, where knowledge and wealth have coaxed Nature into every manifestation of beauty of which she is capable, is my own little private dream of a heavenly mansion. Meanwhile I am doing the best I can with an oblong in a country town! Fortunately, it is on a hill, and out of the way of smoke and dust, having the inestimable advantage of being quite away from a road; still, it is painfully enclosed as to its two long sides with walls of like oblongs belonging to the next-door houses. And in most of these houses there are cats, which seem to prefer a garden where the owner is enthusiastic to one where, as on my left side, the house is empty and the garden in the perfunctory charge of the jobbing gardener who lives opposite. This morning, as I went round my oblong, I found a dear pussy had drawn diagrams all through and over a group of Cottage Maid Tulips, which are planted in front of the bit of rockery running up to the sloping roof of a little tool-house in the sunny right-hand corner against the house. On this rockery, which is made in little terraces and of crumbly yellow sandstone, I have planted all the enervated Saxifrages I could get hold of in the neighbourhood, and they seem very happy. I was tempted by some delightful lists of many varieties of both enervated and mossy Saxifrages and Sempervivums, intending to plant the mossy ones in another little rockery I have in partial shade. But luckily I consulted a Scotch friend who is clever in all ways horticultural, though chiefly interested in *Carti*. "Down here in the west," he said, "some of the most beautiful Saxifrages which succeed very well up north disappear the first winter. They don't mind frost, or the snow which in their native haunts covers them up all through the winter, but they can't stand our mild, damp, muggy winters." After this I confined my ambitions to the few he had tried and found willing, and I am glad to say one of them was the Spider-web Sempervivum which is spreading its little rosettes bravely, but at this time of the year is webless. Some big tufts of *Saxifraga hypnoides*, which seems to be very cheap, judging by the mass of it I got for 6d., I pulled into little bits in October, and dibbled out over a clump of

GYPSOPHILA REPENS IN THE WALL OF THE GARDEN, D'ACCLIMATATION, GENEVA.

while at other times it has the practical advantage of making many garden operations possible which, without such a speedy refuge to fly to, would in this chill-evoking climate of ours scarce be practicable.

It is odd what minute deviations from the every day stir the mind, and help it to shake off that dull crust of routine which it ought to be the aim of all of us to try and get rid of. It is one of the few merits, I think, of winter that places, at other times tame to flatness, seem in fierce or exceptionally cold weather to revert to an older and a wilder condition. Snow admittedly recreates everything—our most familiar paths and shrubberies, may, our very stable runnels, growing quite arctic and hyperborean-looking under its disguise. Apart from snow something of the same impression is

Watsonias, which in this mild climate will do very well in the border all winter if they have a little protection of some kind. Down each side of my oblong I have a wide border, shady one side and sunny the other: along each of these is a gravel path in the most approved plan of the builder, who lays out the garden with as little thought as possible, and in the middle is a rather nice long lawn with an Apple tree at each corner. I bless the planter of these four trees. They are always charming, whether loaded with bloom, with red and green Apples, or leafless, for one is a hoary veteran, gnarled and lichened in the most picturesque way, and in spite of age produced a vast crop of excellent Blenheim Oranges last year, while another, his opposite neighbour, is a cobby little Codlin just old enough to bear plentifully. The two at the other end are very old and not profitable. One, I fancy, is a Tom Putt, and bears very lovely bright red fruit, which was hard and wormy last year; the other only looked pretty and bore little but pink blossom. I put grease-bands round them in September, and on taking them off the other day, found them perfectly crusted with divers insects, which the robins, hedge sparrows and tits, who abound here, ate up immediately off the bands on the ground. I shall put these bands back in June to trap the codlin moth and confiscate its eggs, but I am too fond of the beauty of silver-lichen and green moss to smother the trunks and branches in powdered slaked lime or cover them with a wash of the same and paraffin, as I suppose I ought to do if I were a proper utility gardener. I have hung suet in the branches, and the ties of three sorts hang about and make our garden a *rendezvous*, while numbers of other birds, even a tree creeper, who is so shy, delight in the trees, and seem to find endless employment in picking them over.

There is always something to do, even in an oblong, and the boy who helps me is kept hard at work rolling the lawn and paths whenever the weather is the least fine. To-day I have had a bit of the shady border dug out 5 feet deep, then the soil at the bottom of the excavation was loosened, and a little old hotbed manure worked in with some good loam: over this 2 feet of peat, loam and sand; and when they arrive, a quantity of *Lilium pardalinum* will be planted here, with some Trimardeau Pansies, sown last August close by and pricked out in March, as carpeting. The border here gets a couple of hours' sun, from two to four, and I think these lovely tiger-like Lilies with their spotted yellow, green-tipped blooms, which remind one of that rather misnamed stove plant, *Gloriosa superba* (which is so much less glorious, being so much smaller than they), ought to do well. The Tiger Lilies are of all the autumn flowers the most splendid.

Bath.

GARDEN DESTROYERS.

GARDEN PESTS: THEIR DESTRUCTION.

COOPERATION AMONGST GARDENERS.

It has often occurred to me that the destruction of garden pests, whether insect or fungus, particularly where gardens belonging to different proprietors join one another, would be rendered much easier if there were a certain amount of co-operation among the latter in this respect. What I would suggest is that every owner of a garden in a given district should agree together to use in the destruction of pests the same means and at the same time of year, for it is certain that most pests are able to travel considerable distances with the greatest ease. Take for instance such a common pest as the Goose-

tree to another during a high wind on pieces of the cotton-like substance that they secrete so freely. Even scale insects, the females of which are never winged, and so are incapable of moving from one plant to another unless these touch at some point, may, while in the egg state, be carried about by the wind, as the eggs are small and laid loosely under the body of the female. Thus it is very necessary, if our gardens are to be kept free from insect pests, that we must be sure that our neighbours are doing their best to keep theirs free. It is exactly the same with fungi, except that the only means for their dispersal is by their spores, which are so easily carried about by the wind, as they are so small and light, and in rarer cases on the clothes of persons or on the feet of birds. They are, as a rule, produced in enormous quantities, in many cases each little pustule formed on a leaf producing hundreds of spores. Everyone knows that when a ripe puffball is touched a

SAPONARIA OCYMOIDES, Gypsophila repens, ETC., IN A WALL IN THE JARDIN D'ACCLIMATATION, GENEVA.

berry sawfly, whose grubs do so much injury to the foliage of Gooseberry bushes. The sawflies can easily fly from one garden to another, so that however careful A may be in endeavouring to destroy this pest, and perhaps has succeeded in stamping it out on his premises, yet if his neighbour B is careless in this matter, A's bushes will in all probability be infested by grubs hatched from eggs laid by sawflies bred on B's domain.

It seems to be a law of Nature that every kind of animal or plant should be provided with means of migration or dispersal, otherwise there would be a great risk at times of the species becoming extinct through failure of their food, or from some other cause. Nearly all insects are winged, or some other means are provided for their transport from one plant to another. In the case of aphides, though the majority of individuals are wingless, some, particularly in the spring and autumn, are winged; the American blight, or woolly aphis, besides certain individuals which, being winged, are liable, also their eggs, to be carried from one

quantity of a dust-like material comes from it, and that you may knock it about for some time before you can get it all out. All this smoke-like dust is composed of spores, each of which is so small that it is quite invisible to the naked eye. It is much the same with many of the smaller fungi, so that the air at times is full of these minute spores, which may be carried for long distances. It is very fortunate, however, that only a very small number comparatively ever find a suitable locality in which they can germinate and become fungi, but it is quite certain that, as in the case of insects, if a gardener wishes to keep his crops free from fungoid pests, he must have neighbours that are of the same mind in this respect. It seems to me that it is a matter that might well be taken up by local horticultural societies. Instructions might be printed and given to each member, showing the best means of combating the various pests, and each member should promise when his crops are attacked, however slightly, to use the appropriate remedies at the proper time. Anyone that does

not belong to the society, but possesses a garden in the district, should be pressed to use the same remedies, and everything should be done to render it easy for him to do so. If there were, as probably there would be, several persons who might not be able to purchase knapsack sprayers or other spraying machines, the society might do so, and lend or hire them out to the members; and though at first sight such expenditure might not appear to come within the province of a horticultural society, on second thoughts it will be seen that it will conduce greatly to the quality and abundance of the fruit, flowers, or vegetables grown by the members, and so cannot be otherwise than a proper disposal of the funds of the society. I should much like to see this idea carried out by some enterprising horticulturists, and I feel certain that it would soon prove to be such a success that it would be commonly adopted. G. S. SANDERS.

THE FLOWER GARDEN.

THE HARDY PHYSALIS AS A POT PLANT.

THE Physalises were noted and illustrated at p. 28, and as a grower's views may be interesting, I find the newer variety, P. Franchetti, the one most admired, but, like other plants, it well repays good culture. As regards its growth, the first year from seed it is not a great success, but replanted in good soil with ample room to develop, it is a beautiful decorative object. There are few plants more telling in the autumn in a herbaceous border, and they are useful, as described at p. 28, for decorative work. These plants may be made to answer a better purpose if potted up for cool-house decoration. For this purpose the strong roots should be lifted now, potted up, and the shoots as they appear restricted to half a dozen of the strongest. Plunge the pots during the summer, and by the early autumn the plants will be excellent, and, as they last so long, are most useful. I do not advise seedlings in pots the first year of growth; they are too weak, but these answer well for potting up the second year, and as the plants increase so rapidly at the roots, stock is soon obtained. The plants during growth at any stage need ample moisture and should not be crowded.

G. WYTHES.

SCILLA SIBIRICA ALBA.

WHEN in the spring of 1892 it became known that the stock of the pure white *Scilla sibirica* was about to be offered for sale at one of the public bulb auctions which are regularly held in the Dutch bulb-growing districts every spring, the event was considered to be one of much importance. The blue Siberian Squill had for long been grown in large quantities by the Dutch bulb growers, and for its free-flowering qualities and bright blue colour had always found a ready and ever-increasing sale. Its value as an early-flowering forcing bulb, the happy colour effect it creates in the spring garden, either when grown in masses, by itself, or associated with other early-flowering shrubs or bulbs, all tend to make this Squill one of the most popular of the Dutch bulbs. Like the Hyacinth, it can be grown indoors in quite a number of ways, and it even lends itself to cultivation in water in glasses of small size made specially to suit the purpose, a way of growing this bulb which finds many admirers in Germany. No wonder then that a pure white-flowered sport of such a useful bulb was eagerly bought when offered for sale. This white variety was first found about sixteen years ago among a lot of two year seedling bulbs of the ordinary blue-flowered *Scilla sibirica*. A workman on sorting the bulbs in the autumn for planting chanced to observe one with a satiny white skin. The bulbs of the type being of a deep purplish-black colour, it was at once surmised that this albino bulb would also produce white flowers. The pleasure of the owner (the late Mr. Groenewegen) was great when in the spring this founding variety turned out to be a snowy white-flowered variety of great beauty. Unlike many

other cultural varieties of bulbous plants, the white Squill reproduces itself perfectly true from seed, and by this means gradually a stock was being worked up. In consequence of the death of Mr. Groenewegen the bulbs were put up to auction, and the whole lot, consisting of some hundreds of full size and yearling bulbs, realised about £100—a fairly large sum, it must be admitted. The bulbs were bought by several of the best Dutch bulb growers, who multiplied them as fast as they could, so that now they can already be had at a very cheap rate. Grown out of doors, the white of the flowers, though pure as snow, is apt to get discoloured by rain or spring frosts, and it is, therefore, best to select a somewhat sheltered spot for this dainty bloom. Under glass, however, the white of the flower is exceedingly pure, contrasting well with the luxuriant deep green of the foliage. In order to get the best results in growing this pretty Squill in pots, the bulbs should be planted quite early; they can then easily be had in flower very early. Later planted bulbs when forced not only have a somewhat stunted growth, but they also come into bloom very unevenly. A well-flowered batch of it makes a really beautiful group in any conservatory. JOHN HOOG.

Haarlem, Holland.

CROCUS IMPERATI.

A REFERENCE to this charming Crocus (p. 53) recalls a bright day in February last when we unexpectedly came upon it in one of its native habitats. A little bit of rocky woodland, nestling under the shelter of the towering walls of the Medicean fortress of Siena invited a hunt for sweet blue Violets, nowhere sweeter or bluer than in Italy. Amongst them, piercing through the withered grass of the last season and partly shaded by the leafless boughs of the low Oak scrub, were numbers of our old garden favourite, wide opening their pretty buff and lilac flowers in the sunshine. These were growing, not in clumps, but dotted singly or in twos or threes over the broken ground. To-day (Jan. 25), since this note was begun, a handful of the same lovely little harbinger of spring, brought from the gardens of the Villa Pamfili Doria, has testified to its still earlier appearance about Rome. Many years have passed since Crocus Imperati used to be reckoned one of the earliest ornaments of our unheated greenhouse, for which purpose I can heartily recommend it. It was never tried out of doors in our garden, and it is good news to learn that it is hardy enough to take care of itself in the borders. The flowers of the wild plant, as we find it in Italy, are seldom so large as they used to be under cultivation, but it is identical in all other respects, and here and there specimens equally fine reward a careful search. ROME. K. L. D.

GALANTHUS IMPERATI ATKINSH.

WERE I asked the names of the best dozen Snowdrops I had grown or seen, I should have no hesitation in including among the number the fine variety of *Galanthus imperati* which bears the name of the late Mr. Atkins, of Painswick. Its bold and beautiful flowers are remarkably fine, and it proves a good grower in this garden. In his paper on the *Galanthus*, read at the meeting of the Royal Horticultural Society in March, 1891, Mr. F. W. Burbidge gives some interesting details about this Snowdrop, but it does not seem clear how it first came into cultivation. One would like to know whether it was a seedling raised in this country or a selection from imported bulbs. It was, I learn from Mr. Burbidge's paper, sent out by Mr. Barn at 2s. 6d. per bulb in 1875. Mr. Wheeler, of Westminster, was the only trade purchaser, and it grew well with him, although it died out at Totting. A fresh perusal of Mr. Burbidge's paper shows that he thought this plant different from that *G. imperati* which was sent out by Messrs. Backhouse, of York, in 1877, which is said occasionally to bear misshapen blooms. I got my bulbs of G. I. Atkinsii from Mr. Allen some years ago, and I have little doubt but that they are true to name. While they generally bear blooms of perfect form, they have a tendency to produce

blooms with an additional segment, and thus present a most peculiar appearance when fully expanded. They give an effect like what one might imagine of a number of pure white butterflies poised on the stems. This is, however, certainly a defect, but whether it is due to the soil, the season, or to some inherent defect in the flower I cannot understand. Atkins' Snowdrop is exceedingly fine with its tall stems and usually shapely flowers.

Carsothora, by Dumfries, N.B. S. ARNOTT.

PLANTING FOR SHELTER.

FARM CROPS.

BY shelter is here meant more particularly protection to live farm stock of any kind, and there is only one way in which that can be afforded effectively. It has yet to be proved that much good, if any, is afforded to farm crops by planting trees in the vicinity of fields, except where the plantations are placed to the north of the crops, and then the value of the protection is more apparent than real, unless the sheltering belt is so placed that it does not chill and shade good land behind. It was pointed out to the writer many years ago by a very observant farmer that trees planted in any position where they obstructed the sun's rays at any time between sunrise and sunset did no good, but, on the contrary, injured every kind of crop, and he instanced particularly belts of trees that shut out the sun in the morning or afternoon—that is to say, belts running north and south. Their effect on crops on both sides was bad. The question arose in connection with planting on an estate, and for many years after I watched the fields that had been instanced, and found that the farmer's conclusions on the subject were borne out to the full every season. It was found also that other conditions being equal, more harm was done by shutting out the afternoon than the morning sun, whatever might be the reason. A belt of tall trees ran along the western side of two large fields. These trees began to cast a deep shade on the fields soon after three o'clock, and the shadow lengthened as the sun declined until it reached at least half-way across the fields, which were about 150 yards wide. On the fields on the other side of the belt the sun shone warmly in the long summer days till late in the evening, and the quantity of direct sunshine lost to the crop on the eastern side of the belt, measured by hours after the sun touched the tree-tops in the afternoon, was about five hours. The effect of the shade was very apparent on all crops, but especially upon Turnips and wheat. Stock was taken of the Turnips when they were got in, and it was found that for about 40 yards from the trees they were barely half a crop compared to the crop on the other side of the field where the sun shone all day. The further from the trees the crop got the better it was, and perhaps some would hardly believe that the long shade cast by the trees influenced the crop for nearly 100 yards. The corn grew rank next the wood, but was always longer in coming into ear than that on the other side and never so good. A perfectly open country is undoubtedly best for farm crops, and divisions by means of plantation belts should be avoided except under special conditions. Those who have travelled through the fine corn-lands of the north of France have been struck by the almost total absence of fences and shelter belts. Footpaths only divide the crops as far as the eye can reach. It is the same in Germany, where in well-farmed parts there are no trees nor hedges, and the lands are wind-swept enough, quite as much so as anywhere in Great Britain. I have alluded at length to this part of the subject because in England many estates

are cut up by narrow strips of trees that never yield a crop of timber, nor afford protection to farm lands. London and the landscape gardeners of the past have been responsible for much of this kind of work.

SHELTER FOR LIVE STOCK.

Shelter to cattle and other live stock on farms is undoubtedly provided by plantations laid out in a certain manner. They afford shade in summer and protection from cold in winter; but it is not the extent of such plantations so much as their character and distribution that give them their value. Plantations to shelter live stock need not cover much ground, nor necessarily good ground: they should consist wholly of Firs or evergreen species, and they should be dense and so laid out as not only to afford shelter from cold winds, but to give overhead shelter as well. In ninety-nine cases out of a hundred tree shelters afford protection from cold winds only when the cattle huddle up against the plantation fence on the lee side; whereas to be of real value the cattle should be able to get underneath the trees, but on the warm side only. The plantation need not be very wide, and it should be crescent-shaped with its back to the north. On the north side it should be kept dense and close and protected by a fence, with narrow openings here and there for the cattle to get through to the open south side. Another fence should run from end to end of the plantation, perhaps 10 yards or 15 yards from the outer fence, the object of the two fences being to keep the cattle out of the back part of the plantation. All shelter belts should be close and impenetrable on the cold side, as when the wind can blow through the plantation its warmth is gone. On the south side there should be no fence, and the cattle should be allowed to get under the trees up to the inner fence. A shelter of this kind, consisting of Spruce or Scotch Fir, or both, is soon got up high enough for the cattle to get under the branches. When the trees are that height the lower branches may be trimmed off, but in thinning the trees care should be taken to preserve the overhead canopy. A shelter of this kind is one of the most comfortable that can be devised in all sorts of weathers. The dense packing at the back keeps out the wind and cold currents, and the roof of branches prevents radiation from above. Deciduous trees afford shade in summer, but protection from cold in winter is what is most wanted, and they are next to useless for that purpose.

J. S.

LIBONIA FLORIBUNDA.

This Libonia is a remarkably free-flowering subject, whose bright-coloured blossoms are freely borne throughout the winter months. For some reason or other it is far less popular than it was a generation or so ago, for what reason it is somewhat difficult to say, unless the fact that it needs very careful watering has something to do with the matter, for a batch

of good healthy plants can be soon ruined by an excess of moisture at the roots. Besides this the heavy fogs frequently experienced in the neighbourhood of London quickly play havoc with the plants. This Libonia can be readily struck from cuttings in the spring, and if grown on freely during the summer months, will by the autumn form neat little specimens full of flower buds. They need the temperature of an intermediate house in order to develop their blossoms. Though an excess of moisture, especially during the winter, is fatal to the well-being of the plants, drought is just as injurious, and in the summer overhead syringing is of great service, otherwise they are liable to be attacked by red spider, which quickly injures the foliage and permanently disfigures the plant. As the pots get full of roots, liquid manure is of considerable benefit, with additional doses of soot water, as this latter tends to keep the foliage in good colour, a very important item in the case of the Libonia, whose leaves are apt to turn yellow unless carefully attended to.

treated in the same way. Azaleas can be readily struck from cuttings of the young shoots, particularly if they are produced in a little heat. All that is needed is to take them off at a length of 3 inches to 4 inches, dibble them into well-drained pots of sandy peat sifted fine, and keep close and shaded on a slight hotbed till rooted.

DAFFODIL MME. DE GRAAFF.

It is probable that very few readers of THE GARDEN have ever seen so many flowers at once of Daffodil Mme. de Graaff as are shown in this beautiful photograph of a beautiful thing. It is now nearly a score of years since this, still unapproachably the finest of all the Dutch seedlings, was raised by Messrs. de Graaff, of Leyden; but it is still comparatively rare and valuable, though a vigorous plant and of fairly rapid increase. No exact account of its parentage has ever been given, and it was

DAFFODIL MME. DE GRAAFF AT WARLEY PLACE.

AZALEA DEUTSCHE PERLE.

There is no other variety of Indian Azalea grown to anything like the same extent as this is, for white flowers are always in greater demand than those of any tint, and, apart from colour, this variety possesses many desirable qualities. It is of good free growth, while the semi-double blossoms are, when partially expanded, like little Rose buds, owing to the edges of the petals being somewhat reflexed. In addition to all this it is one of the most amenable to forcing into bloom, and where a collection is grown and treated as ordinary greenhouse plants, it is the first to expand its blossoms. Nearly all the Azaleas flowered in this country are grown in Belgium, and sent here as little bushes fit for 6-inch pots, or as larger specimens. They are invariably grafted on some strong-growing variety, but though this mode of propagation is so generally adopted, it by no means follows that such is the best, as plants on their own roots are infinitely more pleasing than when mounted on a stem a foot or so in height. I have even seen the delightful little *A. roseiflora* which grows naturally in a horizontal manner

in all probability a chance seedling, that is to say, the product of a seed-pod not artificially fertilised. But it is certain, from the character of the flower, that *N. albicans*, the largest of our older white trumpets, was one of its parents, and some large "bicolor" the other. The variety named Dean Herbert is suggested by the form and substance of its perianth and its somewhat late bloom. If it is not ungrateful to find any flaw in so lovely a flower, the one failing of Mme. de Graaff is that it retains too long something of the yellow of its bud stage, and is in danger of fading before its clear ivory-white is developed. Those who are fortunate enough to possess an ample supply of its bulbs should lengthen the season of this Daffodil by blooming a few under glass without any fire-heat. Its delicacy of waxen texture and purity of colour are greatly enhanced by such slight protection.

G. H. ENGLEHART.

AN ARTIST'S NOTE-BOOK.

GARRYA ELLIPTICA.

THE drawing shows male catkins of the Garrya in bloom, and represents also one of the most precious of winter-flowering shrubs. The cutting from which the drawing was made came from a warm corner in a Thames-side garden, where the plant is happier than in many northern places. Few wall shrubs are so leafy and luxuriant as the Garrya; and placed against a sheltered sunny aspect, it bears a profusion of catkins through the winter months, and to gather for the house. They possess a fresh, wholesome fragrance, and upon the plant have a strangely picturesque beauty. Occasionally the Garrya will cover a house front, but only in favourable situations. It is hardier than many suppose, as a plant in my garden was little harmed by frost during the last severe winter. T. E.

MORÆA
IRIDIODES.

WHEN properly treated this is a useful garden plant, but it is rarely met with, notwithstanding its beauty and its early introduction from the Cape, where it was found by Thunberg. Philip Miller grew it at Chelsea, having received seeds of it from the Cape as a white-water Lily. "It is of the easiest culture, and will grow many years together (without parting or removing) in the same pot; requires plenty of water; blooms several weeks in succession during the summer months; produces seeds in abundance, owing to which and its long standing in the country it is now one of the commonest of its tribe in our collections; has no smell." This was written nearly a century ago, when a figure of the plant was published in the *Botanical Magazine* (t. 693). It is grown in pots in a cold house at Kew, where it flowers every summer, but in an early volume of *The Garden* there is a notice of its behaviour in the open air in the Botanic Garden, Glasnevin. "This lovely and distinct looking plant has proved quite hardy at Glasnevin, where it is now (August) in bloom, as it has been through

MALE CATKINS OF GARRYA ELLIPTICA.

(From a drawing by James Cook.)

Vioussenia, and *Diets*. The most remarkable species, and by far the largest of all the plants of the great Iris order, is *M. Robinsoni*, the Wedding Flower of Lord Howe's Island, which forms a large tuft of strap-shaped leaves 6 feet or 7 feet long, and equally long-branched spikes of large beautiful white and gold flowers. There is a good example of it in a sunny greenhouse at Kew, where it has flowered several times.

The difference between this genus and Iris is mainly a geographical one. Mr. Baker says, "The line of limit between Iris and *Moræa* has been differently drawn by different authors, but the two genera are extremely close. I have followed Bentham, who limited Iris to plants of the north temperate zone, and *Moræa* to those of the Cape and Tropical Africa, with one species Australian." The Peacock Irises, formerly called *Vioussenias*, are dainty little bulbous plants with flowers in which the arrangement of colours justifies their name.

W. W.

A VILLA GARDEN. - I.

(WITH SUGGESTIONS ABOUT TREE AND SHRUB PLANTING.)

THERE are so many of these in the country, and so many mistakes are made both in planting and maintaining them, that it seems worth while to point out how easy it is without any material increase of expense to have even in a small space a varied, interesting, and well-assorted collection of hardy trees and shrubs. It usually happens when a small garden is to be planted that the proprietor, even if he be interested in Roses, Carnations, or herbaceous plants, looks upon the

TREES AND SHRUBS

as mere necessary furniture, about the special characteristics of which he is quite indifferent. He therefore makes a contract with the nurseryman to stock his garden for, say, £10, £20, or £30, according to the size. Naturally the latter supplies him principally with those plants of which he has a large stock, and naturally, also, he keeps in stock plants which are easy to cultivate and of rapid growth, and for which there is always a demand, but which are by no means necessarily suitable for planting in large quantities in a small garden. As illustrations of this class of what are called "bread-and-butter" goods I would mention among trees the common Elm, Oak, Ash, Horse Chestnut, Lime, Sycamore, and the London or Occidental Plane; among shrubs, Privet, common Laurel, Portugal Laurel, Spotted Aucuba, and Yew. Of course, the nurseryman will probably add to these a sprinkling of other plants which do not grow quite so freely, and Laburnum, Scarlet Thorn, common Lilac, Ribes, Laurustium, Golden Elder, Almond, and others will be found in the collection. Be this as it may, and however well selected and planted the garden may be, it is quite certain that nursery stuff if left to itself will in a few years be completely spoilt. The stronger-growing trees and shrubs will kill the weaker and will severely injure themselves in the process. Ultimately the big forest trees will grow together, forming a dense mass 30 feet or 40 feet up, darkening the windows and forming a blind where very likely no blind is required, while lower down, where an obstruction to the sight of the road is really wanted, they will have lost their lower boughs. At the same time the unhappy shrubs beneath them will have died, or, if hardy enough to survive in the struggle for existence, will have rambled up in search of light and air, showing twisted, unsightly stems 8 feet or 10 feet long with a bunch of green on the top. Probably during this process of degeneration it will be found that the mischief has not been confined to loss, and some uninvited newcomers will have sprung up in the garden who will not, however, add to the beauty of a shrubbery. They will prove to be probably Elm suckers, self-sown Sycamores, White or Black Thorn and common Elder, and perhaps the stools of two or three deciduous trees which, having been merely cut down instead of being stocked up by the roots, will have vigorously asserted themselves. Now, doubtless during the progress of the above events the owner or owners will have done some thinning out, but will have been prevented from doing so efficiently by the fear of laying his place bare to the road or to adjoining neighbours. How, then, is this state of things to be avoided? and how should a small garden be planted and maintained? In the first place, the owner must realise that if he is to have

AN INTERESTING SHRUBBERY.

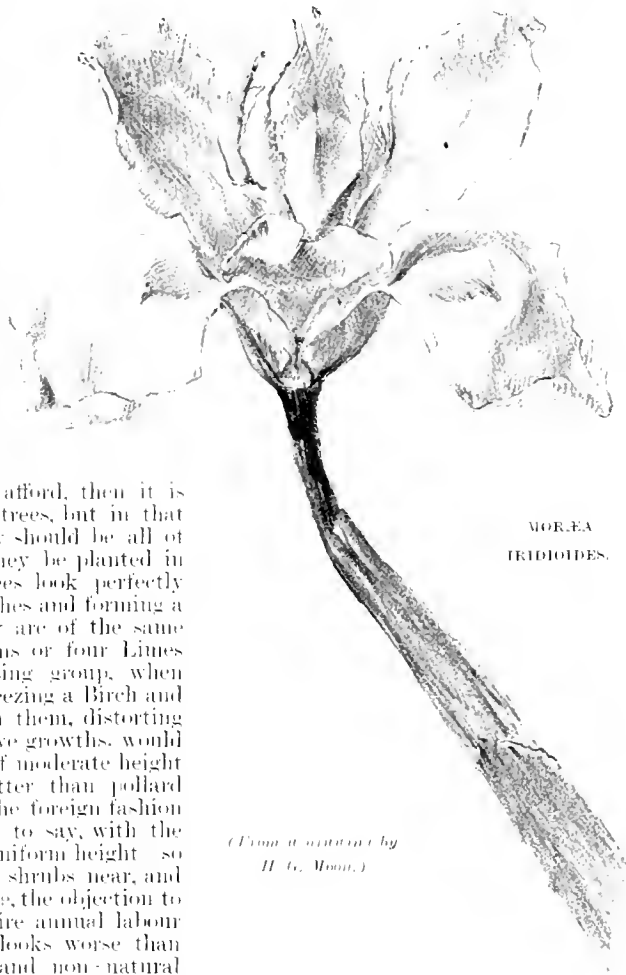

he must not look upon it as a screen, but must make his screen independent thereof. The

proper screen is a hedge, and the material used must be in accordance with the height of screen required. Let us imagine an ordinary villa garden with its two gates and semi-circular sweep, a block of shrubbery between the gates, expanse of turf between the shrubbery and hall door, belt of trees and shrubs on either side of the house and lawn behind, with the space to plant some trees at the end. Let us now consider how to deal with a garden of this kind. First and foremost, it is essential to shut out the road for the sake of privacy and with a view to the exclusion of stray dogs, who are not good gardeners. It may be hoped that the gates will be found to be of solid wood, and not open work. Between these gates I would plant a Yew or Holly hedge: Yew for choice where no cattle are in question, because, taking all kinds of soil together, it can better be relied upon to form a uniform and solid hedge, and because, though neither are bad in that particular, it stands the drip and shade of trees somewhat better than Holly. If it be necessary (to obscure another house that overlooks you, say, on one side of the garden) to obtain a screen much higher than Yew or Hollies can be expected to afford, then it is necessary to fall back upon trees, but in that case it is essential that they should be all of the same kind. Whether they be planted in rows or in groups, most trees look perfectly well commingling their branches and forming a compact mass, provided they are of the same sort. For instance, four Elms or four Limes together may form a pleasing group, when one Lime and one Elm squeezing a Birch and an Acacia to death between them, distorting and disfiguring their respective growths, would look very bad. If a screen of moderate height be required, nothing is better than pollard Limes cut and trimmed in the foreign fashion like a wall on legs—that is to say, with the lower boughs removed to a uniform height—so as to admit the planting of shrubs near, and the top cut square. Of course, the objection to such trees is that they require annual labour and trimming, for nothing looks worse than trees treated in a formal and non-natural manner if they are neglected. If as high a screen as possible be required, no doubt the most rapid grower easily and cheaply obtainable is the Balsam Poplar, but at the same time it is to my eye very weedy and unattractive, and personally I prefer the Lombardy Poplar for this purpose. However, none of the strong-growing deciduous trees, with the exception of the Oak, are suitable for this purpose, and it is very much a matter for individual taste, although I should be inclined to give the preference to the Hornbeam on account of its multitude of very small branches. If a high evergreen screen be required, then I unhesitatingly recommend *Pinus austriaca* on the ground that it is cheap, hardy, dense, warm-looking, and does not readily lose its lower boughs. If an evergreen screen of less height be desired, the *Thuja Lobbi* is not unsuitable, but in that case the hedge should not be cut off, as is sometimes done for the purpose of making them grow more thickly, as in my judgment it deforms them and makes them most unsightly. Assuming, therefore, the necessary screen to have been planted, and, space being an object,

obviously as near the boundaries as possible, let me now say a few words on the

PLANTING.

First and foremost, it will be well to choose the places for the forest trees: by these I mean such as may be expected to reach a height of about 50 feet or 60 feet. Probably in the small area contemplated it will be impossible to have more than about half a dozen of these in such positions that they can attain their full and perfect proportions without let or hindrance from others. And probably out of these six

(From a drawing by H. G. Moore.)

not more than two will have the good fortune to stand perfectly clear as specimens, say one in the centre of the grass plot before the hall door and one at the far end of the lawn behind the house. As it is only in this way by planting a tree singly, so that it shows all its fair proportions clear against the sky, that its full beauty can be realised, it becomes immensely important to consider in a small place which trees shall be selected for this special honour. Of course, the choice is almost boundless, but I will give two that have special advantages, and later on a list of others not quite common, from which selection may be made to suit particular tastes. Of course, I am very far from decriing common trees. None in the world can be more grand than Oak or Elm, but, setting aside the objections to an Elm in a garden, which are strong, one would naturally wish, if a lover of trees, to plant those in one's own little place which have some distinction from the rank and file one is likely to meet in the first field that comes in view. Therefore, I would suggest for the plot before the house a Copper Beech,

principally on account of its conspicuous foliage, and also because it is long-lived and fairly rapid in growth after it is once established. Moreover, it is more tolerant of a heavy clay soil than the common type, although in such a case it is necessary to stimulate its growth at first by a good supply of light soil and garden mould to its roots. At the back I would place a Weeping Lime, because it is hardy, fairly indifferent as to soil and situation, tolerant of smoke, and has a most graceful habit. It is just sufficiently pendulous to make it striking and attractive without being so much so as to have the unnatural, umbrella-like form which makes Weeping Ashes and Elms distasteful to some judges. Should there not be room either back or front for specimen forest trees, then *Pyrus Malus floribunda* with its wealth of pink blossom in the spring and a *Cercis Siliquastrum* with its even more striking flowers may very well take the places of honour.

Now, as to the trees and shrubs that I would exclude from a small garden: The Elm, because of its dangerous habit of letting fall without warning heavy branches, and because of the enormous quantity of surface roots that it makes, sucking out all the good from the top soil and shrivelling up shrubberies and flower borders to an incredible distance: the Oak, because it is intolerant of town atmosphere, and because it is difficult to establish—that is to say, unless the soil be both deep and well trenched you are not likely, except after many attempts, to get a free-growing and shapely tree: the Ash, because it is peculiarly deadly to any undergrowth in its vicinity: the *Sycamore* and common Horse Chestnut, because of their rank growth and coarse, unyielding branches, which render them such bad neighbours in the crowd that is likely to occur in a small space, however much the owner may struggle to avoid it. As to shrubs, I would eschew absolutely the common Laurel, for it grows most rankly to the detriment of better things, is subject to be killed to the ground in hard frosts, and even when it escapes that danger large pieces of it often die off suddenly and without apparent reason. If Laurels are wanted—and their glossy foliage is certainly attractive—plant *caucasicus* or *rotundifolia*. Both of these have the merit of being hardier and more compact than the type. Portugal Laurel should be planted sparingly on account of its free growth, and the variety *myrtifolia* has the advantage of being more elegant in leaf and less vigorous. I do not like Yews in any number in a shrubbery, as they tend to give it a very gloomy appearance, though they are admirable for hedges, or, when old, as single specimens.

COMMON PRIVET SHOULD BE AVOIDED.

unless it be planted merely as a nurse with the irrevocable intention to remove it as soon as it impinges on choicer plants. I should, however, have mentioned that it makes a very fair hedge where the expense necessary for Holly or Yew cannot be afforded. To say a little more about the planting of the garden, I would suggest your planting deciduous flowering shrubs and small trees and evergreen shrubs in the proportion of two deciduous to one evergreen. Do not make the common mistake of planting all your big things at the back and graduating down to the verge, but break your front line at intervals with small trees, such as Cherry or Mespilus. In this way you will gain space for a larger number of trees, and you will also add to the apparent depth and effect of your shrubbery.

VICARY GIBBS.

Alldonham House, Elstree, Herts.

(To be continued.)

THE PRIEST'S GARDEN.

A grey day in Italy—no wind, no sound—as seemed as if the world had forgotten to awake. The day after Christmas we drove along the narrow valley, up into the Olive-covered hills.

Vines hanging from pergolas; long-necked, long-haired sheep sauntering down the dried-up watercourse, full of wild Hellebore and Oleander bushes; cottages, buried in Fig orchards, hanging on the sides of rocks. No sign of bird or any living being, except an occasional peasant hacking at the Olive trees or a row of crouching women picking up the berries. Just now and then a breath passing through the dry Chestnut leaves made a slight rustle and showed that Nature was just alive.

Circling round and up the steep ravines at length we stopped, and saw the little grey clustering village away above our heads. From the rough-paved mule-path we passed into the village street, and found ourselves, after many strange turnings, out upon the little open *piazza* in front of the great white church, surrounded by a sentinel guard of graceful Cypress trees. Standing proudly up on its narrow *col*, with its splendid *campanile* pointing to the skies, the great church seemed to dominate the whole countryside, overlooking on either side the deep valleys below.

As we stood drinking in the great view around us, bounded by distant sea and mountain-range, a young priest, with great courtesy and dignity, stepped silently towards us in his dark, flowing robes, and, with that peculiarly graceful speech of the educated Italian, asked us if we should be pleased to visit his *crèche*. We followed him through a green door adjoining the church, and, entering first, he lighted a tiny lamp which hung in front of the *Bambino*. Gradually as we became accustomed to the semi-darkness we made out the figures—the infant Christ, with a white dove above him, lying in a most realistic manger, with a large cow on one side and on the other a wooden ass. The whole scene, which breathed a devout, simple, and religious feeling, depicted a crowd of modern peasants in gay *festa* costume, bringing various quaint and homely objects as sacred gifts to the Holy Family.

The picture of Bethlehem behind was really beautifully and most tenderly painted, with a flush of early dawn upon it. We asked the priest how he came by the painting, and who had made the little cottages and various objects in the scenery. "Myself," he said, "and the peasant people help me—we have done it all. A lady who was here the other day had just come from the Holy Land, and she said the view was very true to Nature. She took some photographs of my *crèche*." The long, coloured coats of the men and the pretty holiday costumes of the peasant women all came, he said, from Naples. They are made in the convents. He had himself carved the various animals and the little carts full of local merchandise, and to make the whole scene more realistic to his flock he made a model of the old ruined Lombard tower of Sta. Anna, which we had passed upon our road.

As we stepped from the darkness into the light a boy held out a box of *Limosina*. I dropped into it the few coppers I happened to have with me. Presently he ran after me and said, "You need only give me one *solito*, *Signorina*, and you have given five; it is a mistake." Then we strayed to the silent *Campo Santo*, lying amongst the Olive trees on the hillside; facing the east that it might catch the earliest sun, and sheltered by a grove of dark, delicious *flexes*. A Monthly Rose strayed over the wall and lightly clasped the

figure of the Virgin over the ancient door. As we came back down the village street, where the women were making lace, sitting in front of their bright-coloured cushions, rocking a cradle with one foot as they held their little tables steady with the other, the priest came again towards us and asked us if we should care to enter his little garden.

We followed him through another green door adjoining the church on to a tiny Vine-covered terrace, the deep valley dropping sheer

blue hills, the presiding genius of the spot, a magnificent, tall *Camellia* plant in fullest bloom—large, beautiful, rose-pink blossoms, standing out in fresh glory amongst their glossy leaves—the only spot of bright colour in the grey countryside.

"Pick, pick," he said; "I should feel honoured if you will accept them;" and he filled our hands with the lovely blossoms, mixed with a few early *Narcissi* and sprays of *Rosemary* and *Lavender*.

A MOUNTAIN PATH IN ITALY WITH YOUNG CYPRESSES.

below and the great mountains opposite. Scrupulously clean and neat was the little garden, with its paved paths beneath the pergola, its Lemon trees and Vines, its Orange trees and Myrtles, its round bushes of *Rosemary* and *Lavender*, Violets in shady corners; a row of uneven bisent boxes placed beneath the windows in the sun full of seed just beginning to appear; the well of water with the little figure of a saint placed above it half hidden behind the tall plants of *Oleander*. Then suddenly we saw, clinging to the corner of the pergola, gracefully defined against the

As we drove into the common world again down the narrow valley we saw the figure of the lonely priest dark against the sky standing on the lofty terrace beneath the pointed Cypress trees. Father, doctor, confessor, lawyer, scribe of all the *contadini* round, no one is learned or knows anything in San Massimo except the beloved *Signor Prete*. M. C. D.

Winter Aconite and Siberian Dogwood. These form a pretty combination. Flatly noticed a bed of the crimson-stemmed Dogwood, at the base of which the Aconite was flowering. T.

CHRYSANTHEMUMS.

JAPANESE KINDS FOR EXHIBITION. - I.

THE popularity of Japanese Chrysanthemums for exhibition, either as trained plants or otherwise, and also exhibited in a cut state, is still as keen as ever, and there is no doubt that the ever-increasing novelties will keep alive the interest and enthusiasm for a long period yet owing to their great diversity of form and colour. That the newer kinds are much superior to some of the older ones I cannot admit, for when one remembers the magnificent flowers of Mme. C. Audiguier exhibited by Mr. E. Molyneux at Kingston, Belle Paule by Mr. Munro, and E. Molyneux by Mr. Mackenzie, at the Aquarium and Crystal Palace some years ago, I doubt if any varieties of the present day can surpass these; and again the old *Boule d'Or*, *Yellow Dragon*, and *Viviani Morel*, among many others, were as fine as one could wish. But, unfortunately, the Japanese Chrysanthemums deteriorate surprisingly after a few years and become worn out, and with all the new sorts now before us there are none to take the place of some of these. E. Molyneux, for instance, one of the finest coloured Chrysanthemums ever raised, cannot yet be replaced, and I do not think there is any Japanese variety that has held its own so long as this, for even now we find it included in many of our best collections on the show table, though of very poor quality compared with former years.

Scores of articles and books have been written on the cultivation of the Chrysanthemum, and I can add but little to what has already been said, neither do I wish to attempt to teach the successful cultivator; nevertheless, to the amateur and beginner I may be able to afford some useful information. No amount of writing can make the intending competitor successful, as so much depends upon the indomitable pluck and courage of the individual himself. Constant care and attention for a whole twelvemonth must be cheerfully borne if the best results are to be achieved, for, as in many other pursuits, there is no royal road to success. How many times have I heard it remarked, "Yes, so-and-so ought to win; see the convenience he has got;" but depend upon it chance avails but little without determination. Only last year, for instance, the prize for the premier Japanese bloom in the large November show held at the Aquarium, which was probably the finest collection of Japanese blooms that has ever been brought together, was won by an amateur with only one small greenhouse, and this I happen to know was only one of the many grand flowers grown by this enterprising young man.

Forming a collection is often a great difficulty to the inexperienced, which is not surprising considering the immense number of kinds now catalogued, and I propose giving a list of what I consider fifty of the best standard varieties in order of merit, and twelve of the most promising new sorts, as this is of the utmost importance; it is far better to grow a few of the most reliable kinds than a large number of uncertain varieties.

LIST OF SUITABLE KINDS.

Mrs. W. Mease, Madame Carnot, Mrs. Coombes, Mrs. H. Weeks, G. J. Warren, M. Chemon de Leche, Oceana, Phobus, Mutual Friend, R. H. Pearson, Fair Maid, Emily Towers, Miss Nellie Pickett, Lady Hanham, Henry Weeks, Mrs. Barkley, Australia, Chas. Davis, Edwin Molyneux, Lady Ridgway, Mrs. G. W. Palmer, Mrs. W. H. Lees, Souvenir de Mme. F. Rosette, Viviani Morel, Soleil d'Octobre, James Bidenscope, Mrs. J. Carpenter, Chatsworth, Lady Crawshaw, Mrs. Fursden, Simplicity, Rivers H. Langton, John Pickett, Le Grand Dragon, Mrs. J. W. Barks, Mrs. White Popham, Edith Tabor, Emily Silsbury, Louise, Mrs. E. A. Bevan, Pride of Madford, Thomas Wilkins, Mrs. J. Lewis, Mme. P. Rivoire, Mrs. James Bryant, Mrs. W. Seward, Matthew Hodgson, J. R. Upton, Helen Shrimpton, General Paque.

NEW VARIETIES.

Miss Alice Byron, Lord Salisbury, Mme. von Andrée, Mr. H. E. Fry, Mrs. A. Tate, Mme. R. Cadbury, Mrs. W. Morgan, Souvenir de Marquise de Salisbury, Florence Molyneux, Edith Pilkington, Vicar of Leatherhead, W. H. Whitehouse.

Having determined on the number of plants to grow, all of which can be purchased at a very small outlay, excepting the novelties, rooted plants should now be procured and potted firmly in clean well-drained 3-inch pots. The compost should consist of three parts good light fibrous loam, one part well decayed leaf-mould, one half rotten manure or old spent Mushroom bed manure, with a liberal supply of coarse silver sand and a small quantity of wood ashes and bone-meal. This should be thoroughly mixed and used in a moderately dry condition, so that the young plants can be potted firmly without the compost setting together in a pasty mass.

The plants will require a little coaxing for a few days until the roots begin to push through. There is no better place for them than a pit with a hot-water pipe running through, but only sufficient heat should be given to counteract frost. Arrange them on a bed of finely sifted coal ashes quite near the glass; a slight syringing night and morning with tepid water will greatly assist them to recover from the check which they will have received; very little air will be needed the first week, but as soon as the plants show signs of making new growth, give air more freely and dust the points occasionally with tobacco powder to ward off attacks of green fly. After about a fortnight the majority of the young plants should be transferred to cold frames in an open position facing south, nursing on the weaker and later struck plants until they are in a fit state to join the more forward ones.

No matter how careful one may be, some of the best and more delicate kinds will be sure to lag behind in the early part of the season, but one should always try to have the whole of the stock as nearly in the same condition as possible when the time arrives for their final potting.

As regards airing at this season when in cold frames, we are much at the mercy of the weather, and one must use common sense. During spells of cold north-easterly winds very little ventilation indeed will be required, but on the other hand, when the wind is in a genial quarter air may be given freely, removing the lights entirely till last thing in the evening. One must be on guard against frost, as, though comparatively hardy, the slightest frost will injure the young plants at this season.

No hard-and-fast rule can be laid down for the time of the next potting, but many will be found to require shifting on before the others. The whole should be transferred to 6-inch pots, except the very weakest, using 5-inch pots for these. The pots should be thoroughly drained and always used perfectly clean and dry, and it is of the utmost importance that the soil should not be allowed to mix with the drainage, or the latter will become blocked, and the plants becoming water-logged will never be satisfactory. I know of nothing more suitable for placing over the drainage as fibre taken from the loam heap from which the soil has been rubbed out. If a thin layer of this is laid over the drainage, providing worms are rigorously excluded from the soil, the drainage should be as perfect when turned out as it is on the first day.

The soil for this potting should consist of three parts of good fibrous loam, choosing that of medium texture, and one part old Mushroom bed manure passed through a 1-inch sieve. To every barrow-load add a 9½-inch potful of bone-meal, the same amount of wood-ashes or finely crushed charcoal, and an 8½-inch pot of fresh soot, with sufficient coarse sand to render it porous. This should be prepared a week beforehand, thoroughly mixed and turned over every day till used. When everything is in readiness the potting should be carried out as promptly as possible. Never leave the plants standing about, but take out only those which can be dealt with at once and return again to the cold frame. The soil should be made firm at this potting; generally speaking, it can be made sufficiently so with the thumbs, but should the compost be extra light or dry, the potting stick may be used to ensure the whole going together firmly.

The lighter the soil the more firm it should be made. Each plant should be neatly tied to a small stick; well sprinkle overhead and keep the lights closed for a few days. The stronger plants will generally require to be watered on about the third day, but the weaker and more delicate not for a week, or even more, a syringing morning and evening keeping them sufficiently moist. Abundance of air must be given as the plants become established, entirely removing the lights on all favourable occasions, and leaving them off till bed time whenever the weather will allow.

E. BECKETT.

NOTES FROM N. WALLUF, RHEINGAU.

I AM very pleased to see in your issue of January 13 that Mr. W. E. Gumbleton calls attention to *Mischanthus nepalensis* or *Eulalia japonica gracillima univittata*, under which name it is better known in trade catalogues. As Mr. Gumbleton is doubtful about the hardness of this lovely ornamental grass, I am pleased to be in a position to state from many years' experience that it is perfectly hardy, even in our severe winters here in Germany. It is as hardy as a brick, and stood 20° R. with only a slight covering of moss round the roots. If cut back in spring the young shoots spring up very rapidly, and by the middle of June it forms a most ornamental bush about 6 feet to 8 feet in height. Unfortunately, the graceful golden feathery plumes are generally cut down by early frost before they can develop their full beauty. It seems to delight best in a heavy loamy soil, and, if left undisturbed, will soon form large clumps of a most graceful appearance. For imparting a tropical effect in the flower garden, for isolated positions on the lawn or on margins of lakes or streams, it is one of the most ornamental grasses I have ever seen. Its great commercial value, however, is as a pot plant in a cool greenhouse. If well grown in small pots it is a most striking and graceful plant for conservatory and table decoration. The thin wiry stems are clothed with long, slender leaves of a light green, with a conspicuous silvery band running through the centre of each.

Eulalia japonica zehriana stricta is a very handsome new variety, and the finest of all the *Eulalias* ever introduced. It is of a sturdy, compact growth, reaching only about 4 feet in height. The stems are thickly set with stiff, erect leaves, having bars of a clearer, brighter yellow than its parent, *E. japonica zehriana*. As I do not find this charming novelty offered in any of the catalogues of hardy plant growers, I believe it is still scarce in English gardens, but when shown at any of the London horticultural meetings, I have no doubt it will soon find its way into every garden where hardy plants are grown. C. SONNTEG.

FERNS.

BEST BRITISH FERNS.

TO the large majority of people who devote a corner of their garden to hardy Ferns the fact that our British Ferns, in their varietal capacity, are the most wonderful Ferns in the world is entirely unknown. Hence we find that only a few species are used, and of these only the common forms, as vended by the costermonger on his barrow; by the plant dealer, in boxes ignominiously exposed outside their shops like seedling cabbages; or by the local Vandals, who deplete the surrounding country, in ferny districts, to supply per post. Meanwhile, it is only here and there that collections proper exist of the hundreds of far more beautiful forms of these plants, which have been found wild in the first place, and in many cases subsequently highly improved by selective culture. At Kew, thanks to contributions and bequests, there is a magnificent collection of these varietal forms, and as they are in all cases perfectly hardy and easy of culture, we cannot too strongly advocate their extended introduction and adoption as decorative plants for

cool conservatories, cold frames, and sheltered rockeries out of doors. To this end we propose giving a brief outline of the finest varieties, and in this connection we may mention that the large majority of them are obtainable from the nursery-men who make these a specialty at such moderate prices as place them within the reach of all, especially when it is considered that they are all perennial, and once established last a lifetime. Nature, in fashioning these varieties, distributes them usually solitarily among the common forms wherever these are fairly abundant. Of "how it is done" we know absolutely nothing; all we know is that the Fern hunter who assiduously inspects the masses of Ferns which grow in many places so abundantly—in hedgerows, on old walls, in woods, in shady glens, and on the hillsides and moorlands—every now and again comes across a specimen which is altogether differently fashioned from its neighbours of the same species. All the tips may be elegantly tasselled, all the divisions

feathery; the crested, or tasselled; and the multiform, or "curio" types. Of these we incline to the belief that the plumose are the most beautiful. In these the normal simple grace of the species is maintained, but enhanced by such an amplification of the foliage as to put the common forms far in the background. In the Lady Ferns (*Athyrium Filix-foemina*) and Shield Ferns (*Polystichum aculeatum* and *P. angulare*) we have the grandest forms of these. *A. F. f. plumosum* Horsfall and *A. F. f. p. Axminster* are two wild finds of great beauty, and quite distinct from each other. The first, there is reason to believe, is the parent of *A. F. f. Kalothrix*, an uniquely delicate Fern, with fronds like spun silk or glass. *A. F. f. p. Axminster* has, however, proved itself the mother of not merely an individual gem but of a queenly race, sporting first into *A. F. f. p. elegans* Parsons, a refined edition of itself, and then through that into the glorious strain of *A. F. f. plumosum superbum*, a beautifully tasselled form,

lengthens out all its tips into mossy-looking tails to cap the climax. In addition to these raised forms we have some charming original finds. *P. a. p. Pateyii* and *P. a. p. Wollastonii* are both gems, while in the allied species *P. aculeatum*, *P. a. pulcherrimum* is really the plumose form of that species, but does its spitting in a slender, graceful fashion entirely its own. Among the Buckler Ferns, there is not so much in the plumose way, as *Lastrea Filix-mas Bollandie*, though good, is defective in make. *L. p. m. cristata* has given us a silky form in *L. F. m. fimbriata cristata*, and *L. montana* has yielded several beautiful plumose forms, Airey's and Whitwell's being the finest. The common Polypody (*P. vulgare*) has given us many forms of *P. v. eumbricium*, known as the Welsh Polypody, though found in other places as well. All these are beautiful, the finest being *P. v. c. Hadwini*, Barrowii, Oakleyæ (a dwarf), and *Prestonii*, the last incomparably the best. Even our little Black Maiden-hair Spleenwort (*Asplenium Trichomanes*) has given us several lovely plumosums (*A. T. incisum*), of which Clapham's form excels all. The plumose form of the Sea Spleenwort (*A. marinum plumosum*) is a grand variant of that simple species. Our true Maiden-hair (*Adiantum capillus-Veneris*) in the same direction has done its best to imitate *A. Farleyense* in *A. c.-V. comubiense*, and quite succeeded except in size and tint, and finally among the divided Ferns, *Blechnum Spicant* has given us *B. S. pl. Airey*, a fine three-divided plumose form of that pretty species.

The Hart's-tongue, despite the normal strap-like simplicity of its fronds, has managed to yield some exceptionally fine things by frilling and fringing. *S. v. crispum*, the plumose variety of this species, has been repeatedly found, and a well-grown plant of the kind is a decoration worthy of any post of honour. As all the barren *crispum* are good we need hardly name them, except that *S. v. c. grande* Wills is the finest. The frilled and fringed varieties have been raised by selection. *S. v. crispum fimbriatum* Staunfield and Cropper constitute the finest strains, which include some which are tasselled beautifully to boot. Naturally this species forms a delightful foil to the divided ones, and as it is quite evergreen pays its rent, so to speak, with interest.

With regard to the tasselled varieties their name is legion.

In these the tips of fronds, side divisions, and, in the best forms, even the ultimate divisions, are tamed out into tassels, giving a peculiarly rich and ornate appearance to the plants. The best of the Lady Ferns are *A. F. f. sup. pericristatum* and the whole of the *superbum* section, *A. F. f. pericristatum* Consens, *plumosum pericristatum* Consens, *regule gemmatum*, *Victoriae kilnshiensis*, *Elworthii*, *setigerum* (many forms) *Vernoniae cristatum*, *congestum cristatum*, and *corymbitermum*; but this by no means exhausts the list of gems.

The Shield Ferns in their various grandiceps forms *Abbotte*, *Talbot*, *Jones*, and others are splendid; *P. ang. cristatum* *Wollaston*, *pericristatum* *Moly* and ditto *Grey*, are beautiful, and typical of many others which run them close. The Buckler Ferns have given us the king of the male Ferns (*L. p. m. cristata*), a tasselled giant, and, if properly treated, a fine Tree Fern. *L. p. m. ramosissima*, *L. p. m. polydaetyla* *Wills* and *Dadds* are grand companions to it, and by selection and crossing we have a number of smaller crested ones, such as

DOUBLE SEA CAMPION (SILENE MARITIMA FL. PL.)

may be cut and recut into extra laciness, or crimped or crisped in many different ways; sometimes the whole plant is dwarfed and congested into a miniature edition, and sometimes enlarged into a grander one. Furthermore, these varied types may be combined, and, in short, since two such finds are rarely identical, the accumulated distinct forms are very numerous.

Then, too, it has been found that spores of such forms not only yield their type truly, but are apt to vary still more, and, finally, that if two types be sown together, they are capable of crossing and affording progeny in which the two characters are combined. All this, of course, apart from its indication of an interesting diversity, means that there is an absorbingly interesting field of culture open to those who take up Ferns as a hobby, and do something more than merely buy plants and take care of them.

To come now to the best, as space is limited, we may say that the varietal forms may be classified roughly into three types, the plumose, or extra

which in its turn yielded two distinct sections, tasselled and plain, among which *A. F. f. plumosum* *Drucery*, *uncrested*, and *A. F. f. sup. pericristatum*, in which even the fourth divisions are prettily tasselled, rank as the finest amongst a score of distinct and charming forms. Keeping still to the plumose forms, we come now to the plumose Shield Ferns. Some of these can only be compared to *Todea superba* for exquisite division of parts. A wild find of Mr. Moly's (*P. a. decompositum*) yielded, in the hands of Col. A. M. Jones and Dr. E. F. Fox, a number of densely divided plumose forms such as described; of these, *P. a. plumosum densum*, *P. a. p. laxum*, *P. a. p. robustum*, and last, but by no means least, *P. a. p. Baldwini*, excel all exotics in feathery loveliness. Of equal rank, but of less distinct origin, is *P. a. p. Esplan*, a plumose starfish, so to speak, and *P. a. p. Pearson* ranks but little lower. Finally, there is Messrs. *Burkenhead's P. a. plumosissimum*, a seedling probably from one of the foregoing, which, after doing the apparent utmost in feathery divisions,

L. p. m. crispa cristata, angustata cristata, and a host of others. *L. dilatata crispa cristata* Oseroff and *polydactyla* are both good native finds, which, however, the Azores have eclipsed by *L. d. foliosa cristata* and *L. d. f. digitata*, which have the advantage of being evergreen. *L. montana* (the Lemon-scented Fern) has provided a regiment of good things, tasselled and otherwise. *Asplenium Trichomanes cristatum* is a pretty dwarf. *Polypodium vulgare* has decked itself similarly in *P. v. cristatum*, *P. v. grandiceps* Fox, ditto Forster, and ditto Parker—the last all crest; and finally the Hart's-tongue has eclipsed every other species by the multiplicity and multiformity of its tasselling, ranging from merely forked tips down to a transformation into a seeming tuft of the finest moss (*S. v. densum* Kelway). Space utterly precludes an abstract even of the good forms of this species; it would be too invidious, and we can only say that those listed for sale may fairly be assumed as constituting a selection of the best, on the theory of "survival of the fittest."

CHAS. T. DRURY, F.L.S., V.M.H.

PTERIS SCABERULA.

This is one of the daintiest of small-growing Ferns, and is also suitable for small glasses in rooms. In almost any arrangement its pretty fronds may readily be singled out, and when grown in a cool house it is valuable for the way it endures after being detached from the plant. Though not at its best in mid-winter, it may be had in good condition with a little care. Formerly it was usual with some growers to water this plant freely overhead, but when so treated not only was disfigurement of the fronds more readily brought about, but the fronds were less useful for cutting and decoration generally. Grown in a large way for its fronds alone, it is a good plan to plant it out on the front stage of a greenhouse. For this purpose 3 inches of soil are ample, as it is not a deep-rooting plant, though covering much surface space with its freely spreading rhizomes. In this way it is surprising the amount of good material a square yard will produce, and no one having such a corner to spare and once having tried it thus would go back willingly to culture in pots. Little warmth is required to grow this Fern successfully. The most suitable mixture is one of peat and loam in equal parts and a very liberal dressing of burnt earth or broken brick rubble, the former being excellent and more easily obtained of the required size. During growth water may be freely given, and in such a mixture of soil as that suggested will do no harm. The objection to planting out comes when small plants are required for furnishing. For this purpose the plants are best kept under pot culture, though even then occasional pegging of the growths may be requisite.

E. J.

DOUBLE SEA CAMPION.

(*SILENE MARITIMA* FL.-PL.)

THE Sea Campion is a pretty thing even in its single wild form, as it grows widely trailing over rocks close to the sea, with its root thrust deeply into the rocky clefts. But its double garden form is a much better plant. The doubling of the flower makes it surprisingly large, and gives it almost the look of some good smooth-edged Pink. It is a plant that adapts itself readily to the wants of the rock garden, being handsome both in general effect and in detail, and has the partly hanging habit that is so valuable among well-placed masses of stone. The milk-white bloom and smooth bluish leaves are delightfully harmonious in colour.

Coreopsis verticillata. This perennial sort has something of the feathery lightness of the annual *Coreopsis*, and makes very pretty clumps in good deep soil. The foliage is thread-like in fineness of division, and the flowers, though small, are borne in abundance. They are of a clear yellow without any markings. As it grows only about 2 feet high, it is never straggling. It is perfectly hardy, and increases by underground stems in a moderate manner. The effect of a good clump is very distinct among bolder-leaved things. —T. J. W.

THE FRUIT GARDEN.

APPLES UPON WALLS.

THIS mode of growing the Apple is not often adopted where it succeeds under ordinary treatment, but in cold northern and elevated districts where standard and bush trees are unsatisfactory it may be carried out successfully and with advantage. An instance to bear this out may be cited. At Crimmoigate, Aberdeenshire, which is situated about three miles from the sea-coast, and is far from being a favourable position for hardy fruit culture, Apples as standards and bushes were a failure (I am referring to upwards of thirty years ago). The trees that were grown certainly sometimes had crops of fruit of inferior quality, but were scarcely worth the space they occupied. There were in the same garden two walls devoted to Apples, from which full crops of good fruit were obtained. The trees were excellent examples of skilful culture, being beautifully trained in the fan and horizontal methods, and when thickly clothed with blossoms or carrying crops of fruit they furnished a rare spectacle in that district.

At Goodrich Court, Ross, some varieties are splendidly grown upon walls by Mr. Spencer, viz., Cox's Orange Pippin, American Newtown Pippin, Margil Melon Apple, American Mother, King of Tomkins Comty, Lane's Prince Albert, &c. Fruits from some of these have been successfully exhibited at the Royal Horticultural Society's Crystal Palace shows, and perhaps the best dish of Melon ever exhibited in England was amongst them, and secured a first prize for Mr. Spencer in 1896. This points to the fact that even in our best Apple counties something is to be gained by this mode of culture. By it at least the colour and size of the fruit are improved, while it is easily protected from birds and is less exposed to wind than when grown in the ordinary way. It must not be inferred that I recommend this way of growing the Apple in a general way. Most varieties can be grown well enough in ordinary Apple districts without the assistance of walls, which are too restricted in extent in most gardens to be profitably utilised by the Apple, and delicate kinds, such, for instance, as Calville Malingre and Melon, can be very well dispensed with. It is in districts unsuitable to ordinary culture that I advocate its adoption, and in such a climate as that of Crimmoigate it is certainly deserving of being carried into practice.

In warm situations east and west walls or fences answer well for this purpose, but in cold and elevated places those with south aspects are preferable. The form of the trees is of secondary importance. Fans, horizontals, and cordons answer equally well. In choosing varieties, however, preference should be given to those upon the Paradise stock, as these freely form fruit-spurs and are not too robust in habit. Varieties that bear most of their fruit upon the points of young wood, of which Cornish Gilliflower, Lady Sudeley, and Gaseigne's Seedling are types, are unsuitable. Young trees planted upon rich garden soils are liable to make strong, unfruitful wood, but this can be checked by root-lifting and pruning, and a free-bearing state is thereby brought about.

THOS. COOPER.

LATE APPLES.

THE more fine rich-coloured Apples are seen in January and February, the more is manifested on tasting them how little have they repaid their keeping. Of some twenty or more varieties put before the fruit committee at the Drill Hall the other day as late fruit, not more than two or three had proved to be worth the trouble bestowed on them. All the rest should have been consumed in December. That is not what the public want. Those who desire to have really good fresh, juicy, brisk-eating Apples now and for the next two months should for kitchen purposes secure Prince Albert, Hornsea's Pearmain, Newton Wonder, Northern Greening, Wellington, and Norfolk Beaufin. There are probably no better half-dozen keepers in brisk,

plump condition than those named. All are good, but Prince Albert and Wellington are specially so. Myriads of fruits that in January and February look splendid and firm are found when tasted to be lifeless, mealy, and devoid of flavour. They are several weeks past their best, and beyond that best no variety should be kept. Then of eating Apples for late work, that delicious variety Cox's Orange Pippin, when allowed to hang late and kept in a cool place not too dry, keeps excellently up to the end of January. To follow that there is no better one than Cackle Pippin, one of the very best flavoured of Apples, which has nice crisp flesh. Adams' and Mannington's Pearmain will keep good till the end of February generally, and Rosemary and Brownlee's Russets, Duke of Devonshire, and Sturmer Pippin make up ample for the latest table supply. We get in new Apples very few additions to the latest ones, but many quite early, of which almost worthless section we have so many, and mid-season varieties. Of these latter we have enough to satisfy all needs for the next twenty years. But in that time we must expect to see some fifty new varieties added.

A. D.

TREES AND SHRUBS.

PTEROCARYA CAUCASICA.

SEVERAL tree-lovers, after seeing at its best our remarkable specimen of the above tree, have said that the sight of it was well worth a long journey, an observation that doubtless applies to anything that is the best of its kind, and I think we may claim this for this particular specimen, as all inquiry has failed to discover anything to equal it. It is still growing away rapidly alike in bulk and the spread of its branches, the latest measurements giving the circumference of stem and spread of the branches respectively at 16 feet 6 inches and 315 feet. The fact that the habit of growth of many of the huge branches is not far from horizontal, and about equally balanced on the north and south sides, caused the stem to split at the point from whence the branches sprung. It was not deemed advisable to spend the amount of money that chains and bands would have entailed, so the mischief was partially checked by placing huge props beneath the lower branches. As the latter, however, continued to grow rapidly until the tops touched the ground, the leverage naturally increased, until there was a strong probability the tree would split asunder, so with the view to prevent this I was reluctantly compelled to remove some of the lower branches and so release the strain, I say "reluctantly" because one does not like to remove even a small branch from a handsome tree. But it was absolutely necessary in this case, and the operation was performed so as to interfere as little as possible with its level outline. So far as its summer appearance is concerned, it has not been seen at its best for several seasons, and last year was no exception to the rule, a late spring frost nipping both the young growth and the catkins. The foliage broke again later, but the catkins were nearly all destroyed except a few in the central part of the tree. The early development of leaf and susceptibility to frost are naturally somewhat detrimental to the species as an ornamental tree; but as when seen at its best it is quite unique, it ought to find a place in all large collections.

E. BURRELL.

Chermonth.

GOLDEN ELDER AND PURPLE HAZEL.

ONE of the most effective combinations of hardy foliage trees in the garden can be made by the employment of Golden Elder and Purple Hazel. The only condition needed to make this quite effective is an open situation fully exposed to the sun, so that the full golden leafage may be perfectly developed. If there is the least shade from overhanging trees, the Elder then assumes a dull green and is quite ineffective. No plant that I know will grow better under what might be termed

unfavourable conditions as to soil: it will grow in any kind, heavy or light, and as to its propagation nothing is easier. Stout cuttings 1 foot long of the current season's wood taken off in October, cut square across below a joint, and firmly dibbled into sandy soil, will make nice plants in one year.

Instead of "dotting" the plants here and there in the shrubberies, as is too often the case, mass them together, not less than a dozen, giving them just enough room to make their annual growth. In front of the Elder plant a single row of the

Hazel, giving them sufficient room to stand clear of each other. An annual close pruning of both subjects down to within an eye or two of the base will induce a vigorous growth of young shoots every year and larger leaves, which will be more intensely golden than those coming away less vigorously. During the summer, when the shoots are, say, 2 feet long, nip out the point of each; this also emphasises the colouring. The Hazel, too, may be served in the same way. This yearly pruning ensures a compact growth.

E. M.

PALM HOUSE AT STREATHAM HALL.

THE accompanying illustration represents a view in the famous Palm house at Streatham Hall, Exeter, the residence of Mrs. R. Thornton West. This Palm house is one of the finest in the west of England, measuring 71 feet long and 40 feet wide. It is delightfully planted, Ferns, Palms, and foliage plants being associated with rare judgment and artistic effect.

BOOKS.

A book about lawns and cricket grounds.

We have received a book about "Garden Lawns, Tennis Lawns, Putting Greens, and Cricket Grounds," written by Messrs. Sutton and Sons, of Reading. It is a book fit for the library, well printed, well illustrated, and charmingly produced in every way. The information is thoroughly practical, and should prove of great value in the treatment of garden lawns and cricket grounds. The following extract about "Improving Old Lawns" (p. 25) will show how sound and practical is the information:

"IMPROVING OLD LAWNS.

"Old lawns become thin and bare from various causes, such as poverty of the soil, the encroachment of weeds, overwear, or because the seeds originally sown were not suitable for the land. Stimulating the surface by a vigorous use of the rake is one means of improvement, and the work will be more effective after the lawn has been mown. The immediate effect is apparent ruin, but the grass will speedily recover from the rough treatment and look the better for it. Over the loosened surface sift or lightly press some loam mixed a few days before use with Sutton's lawn manure in the proportion of 7 lb. to 10 lb. of the manure to a medium-sized barrowful of soil, and lightly rake the surface to ensure even distribution. After an interval of ten or fourteen days, sow a mixture of renovating seeds; rake these in, put the roller over the entire surface twice in different directions, and keep birds off.

"The work can be commenced at the end of January or beginning of February, supposing the weather renders it possible; and as the old turf will protect the young grasses from injury by frost, the seed may be sown early in March. An autumn sowing of renovating seeds can, however, often be made immediately the grass can be spared from play at the end of the season, but as a rule it must not be later than the middle of September. After that period sowings have occasionally been made with success, but they are not to be relied on. The possibility, already alluded to, of losing the clovers in winter applies here also, and the sward should be examined in spring to ascertain whether another sowing of seeds is necessary.

"A weak-growing sward may be stimulated by the application of 1 lb. of lawn manure stirred into 10 gallons

"Garden Lawns, Tennis Lawns, Putting Greens, Cricket Grounds." By SUTTON & SONS, Reading. London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd. Price 2s. 6d.

PALMS AND FERNS AT STREATHAM HALL, EXETER.

of water. This quantity will suffice for a rod or perch of land, and it should invariably be administered in the evening. Dry artificial manure scattered over the surface in hot weather will certainly scorch the grass.

"We have occasionally been asked whether a lawn which is thin might not be allowed to thicken its herbage by seeding. A more disastrous course could not be pursued. It has exactly the opposite effect to that desired, by weakening the standing plant without any compensating advantage. The little seed that is produced will be shed by the coarser varieties, and if these seeds, instead of being blown by the wind on to the nearest border, take root in the lawn, the herbage will be deteriorated, and it may take years to remedy the injury."

CORRESPONDENCE.

NARCISSUS PALLIDUS PRÆCOX.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Mr. Arnott, in your last issue, asks for experiences of *Narcissus pallidus præcox*. I have had it growing here for some seven years, since I made my rock garden, and although it took a little time to establish, it has for some years been very happy, and is increasing. I have it planted on north slopes, more or less steep. The soil is fairly light, and our climate here is a very moist one, so that it gets an abundance of moisture. Encouraged by its growth in the rock garden, I have more recently planted it on a grassy bank with the same aspect, where, so far, it seems to be doing well.

SAMUEL TAYLOR.

Bicknall, Harborough, via Leicester.

THE WISDOM OF ROOT-PRUNING.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—I should not have troubled you with further remarks upon this subject had not Mr. Wythes (see page 106) evaded mentioning the real point that I took exception to in his article, viz.: "It is an easy matter to check gross growth at this season, and by so doing ensure a full crop next year." The fact of this having been written, as Mr. Wythes states, early in October instead of at the time published, viz., December 30, does not in the least detract from the misleading nature of the sentence, for, supposing root-pruning is done early in October, it does not ensure a crop the next year. As I before stated, root-pruning, if executed in the autumn, does not guarantee or promote fertility the following year, but it invariably ensures a good show of fruit buds at that time. Your correspondent's remarks about nurserymen's practice of making up their fruit quarters in March or April are not relative to the real question. Surely Mr. Wythes knows that this is not done with a view to ensure a crop of fruit the following autumn, or because it is considered the best season for transplanting, or root-pruning fruit trees for that matter, but simply to fill up vacancies caused by lifting trees to supply customers, and by so doing save wasting ground.

AN OLD PRACTITIONER.

DWARF POINSETTIAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—In reference to Mr. Crawford's note and question on the above in *THE GARDEN* (page 91) I am induced to send the following remarks: When the plants have finished flowering, they are dried off and stored under the stage of the geranium house, and are removed in April to a heated pit, gradually exposing them to full light and sun. A few cuttings are rooted in June and kept on until September. The old plants are placed outdoors during July, August, and September, keeping them in full sun. The early plants or cuttings are potted on into 2½-inch pots, they grow about 3 feet high with

bracts 20 to 21 inches across. July and August cuttings are put into 6-inch and 4½-inch pots, and they grow from 1 to 2 feet high, with bracts 18 to 20 inches across. The September cuttings are rooted and grown in 4-inch and 3-inch pots, and are from 3 to 9 inches high, with bracts 12 to 18 inches across. Several plants are grown in 3-inch pots, and have bracts 14 inches across. The plants are only shaded while rooting in the propagating pit; at every other stage of growth they are exposed to full sun and cool treatment until early in December. The cool temperature in which they are grown makes them most useful for house decoration. I may add that a quantity of them were exhibited at the Royal Aquarium last December. After being three days there and two nights on the road, I used them out and in pots for house decoration until about a week ago, when the plants were stored away. The Poinsettia is an old plant in our gardens, but a most useful one, and is always admired whenever it is well cultivated. The secret if any is to avoid shade and strong fire-heat and give air freely.

JOHN FLEMING.

Wycham Park Gardens, Slough.

DEEP CULTIVATION OF THE SOIL.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—The discussion which has arisen over Mr. E. Beckett's reference to his method of deep trenching his garden soil at Aldenham shows how much stress gardeners lay upon deep culture. There seems to be two reasons why this deep trenching is not popular in many, and especially in amateurish, directions, the first being the arduous nature of the labour involved, and second the dread lest manuring subsoils should be productive of more harm than good. Now it has been shown that the important element in the Aldenham drastic method of trenching is found in the liberal dressings of manure which such exposed subsoils receive there. That is a feature which too few can adopt; hence those who have brought crude subsoils to the surface too often have, because no special food applications could be furnished, found failure. Now by far the safest course for all who have indifferent manurial means is when trenching, let the subsoil be what it may, to break it up deeply with a fork, or even, if need be, with the aid of a pickaxe. They will thus enable air to penetrate, sweeten, and even to help fertilise such low soils, though left where Nature found them. But if, in addition, there can be added on the surface of these low broken soils a dressing of manure, decayed garden refuse, or other vegetable material that will gradually decay before the topsoil of soil from the next trench is cast on to it, then very great good is done. The manure dressing washes into and becomes gradually incorporated with the crude subsoil, and in that way greatly promotes fertility. In the summer, when the air is heated and the surface soil is dry, root crops are encouraged to go deep into this subsoil, because it is now loose and porous, finding there both food and moisture, so that the gain is then great. But such trenching and manuring benefit the crops for some two or three seasons, and at the end of that period, when trenching again takes place, the poverty, crudeness, or sourness existing in the subsoil in its virgin state has largely disappeared, and a portion of it may be brought to the surface and be incorporated with the surface soil. In that way and by judicious treatment all subsoils are in time made fertile and sweet for some 24 inches in depth, and where soils are naturally deep even to 36 inches. To so great a depth vacant soiling-class kitchen gardens is invariably trenched each winter, and where cropping is judiciously managed, all the vegetable area is thus deeply trenched about every three years. It is only by such gradual process that kitchen gardens, the most productive of all soil areas, have been brought up to their high pitch of fertility. The work was not of one year, but of many. One of the remarkable results of this constant deep working is that areas continue to be wonderfully productive for generations—aye, even for centuries. There is no such thing as soil exhaustion such as we hear of so often in connection

with agriculture to be found in the gardener's vocabulary. The gardener understands that soil is, after all, but a rooting medium, and that it is but needful to replace in it what crops have taken from it to enable it to be productive for ever. But to enable so much, whether temporarily or permanently, to be done, deep cultivation is indispensable. The cause of decay in agriculture is found in lack of deep culture. Gardening, on the other hand, owes its success to deep culture more than to any other cause. Large trees send their hard woody roots deep down into hard subsoil and there find sustenance. Break up and manure these subsoils and the tender roots of garden crops can do the same. That is the basis of the gardener's cultural practice.

A. D.

SIR.—I would advise all those responsible for the articles appearing in *THE GARDEN* on the above subject to endeavour to keep in the proper groove of this interesting subject. I certainly fail to see what part "big Oaks and Beeches" play in this subject (see "E. H. J.," *Hampton Hill*, p. 88) of quick growing kitchen garden crops; also turning up a meadow and getting a good crop of Potatoes (see D. B. Crane, page 89). May I ask if the readers are to take it that this good crop of Potatoes was produced from the bottom 2 feet or 3 feet of clay or sand suddenly brought to the surface and immediately planted? What the readers (including myself) would like to know is how the quick change is brought about in such a wholesale way for immediate planting, especially for the small seed departments. I doubt whether anyone advocating "deep cultivation of soil" has practised it more than myself, as far as my means will allow. The present writers on the subject seem to ignore the chief point, viz., draining. I know what it was some years ago to deal with a plot of ground that had been trenched so many feet deep in clay without draining. When I was called in here it came to my lot to let off tons of water bottled up through this injudicious trenching—this, too, on a hill. In the advice laid down in *THE GARDEN* (January 13), in bringing a London clay to the surface, naturally strikes any practical reader as rather a drastic measure, viz., bringing up about 2 feet of such stuff to be afterwards rendered fit for immediate cropping. To deal with a plot of ground such as stated, consisting of so many inches of top soil, the rest London clay, broken up to a depth of 3 feet, any practical person knows that this so-called London clay must have a considerable amount of opening material added, or it must run together again. I may suggest that it is quite likely that very few would have such an amount at hand necessary to render such clay porous. The most practical way to go about repairing the difficulty is, first, to roughly drain such land, not less than 3 feet deep; secondly, portion off that part of the garden you can spare for burning. Turn this right over right down to drains, then start a fire built with a quantity of faggots and cordwood in the shape of a huge sugar loaf, fill up the opening with fine wood, then build the London or heavy clay 1 foot thick all over this, adding small coal to each layer when you have covered the whole pile of wood in, except one side where you intend starting the fire at top. It will astonish a novice the amount of material or clay this class of fire will burn. These fires are governed by feeding or adding the clay as the fire shows through, and adding the coal-dust more or less according to the way it is burning. It should leave the clay a mild ballast material, not burnt to a hard ballast. Burn about half the clay that is brought to the surface. This should again be well mixed back through the remaining part of the clay as the trenching again proceeds with other light material at hand. The workable surface will again be brought back to the top again, to be dealt with in the ordinary way. One will now have from 3½ feet to 4 feet of good a-rated soil, and the roots of kitchen garden plants will go well down amongst it. Deep cultivation of suitable soils is quite different to that of dealing with a London clay. Let any practical person consider the amount of opening material it would take to render 2 feet of heavy clay brought to the surface workable for any ordinary kitchen garden, &c., and also consider

what sort of a pincushion look the quarters of a kitchen garden would appear like, also what the walks would look like after a storm. I maintain that the only practical way to deal with a London clay is to well drain, and otherwise render it workable by fire, but on no account prefer the bottom clay to the existing workable top spit, otherwise the plot will be ruined for some considerable time. I have just recently had to deal with a so-called London clay where the men could hardly relieve their tools. Now, to bring such conditions to the surface would be nothing short of madness. However, I dealt with this special plot quite another way, which I hope to convey by permission later on, the success of which has been a great pleasure to more than myself. I can only again add that no practical person can ever run against good deep cultivation, but to try to convey such drastic measures as some would suggest is absolutely unjust to any novice. It cannot be too strongly impressed that a London clay is quite different to a strong loam. The latter is a gold mine compared with the former. I thank Mr. Beckett for his reply (page 109). I hope to be clearly understood. My objections are burying a good top spit, to be replaced with what is known as a London clay, which Mr. Beckett now informs us is very simply dealt with, by drawing drills in it and filling the same with fine soil for seed sowing. Now I wonder what practical gardener would ever bury a good top spit 3 feet deep, and expect it to have the magnetic power to draw down roots of kitchen garden material through 2 feet of the so-called London Clay. Now I am quite sure Mr. Beckett would not have us believe that he pursued this practice to produce the long tapering roots of Carrots, Beetroots, Parsnips, &c., which he so well exhibited in London last autumn.

JAS. R. HALL.

For Warren, Cobham, Surrey.

NOTES OF THE WEEK.

Gardeners' Royal Benevolent Institution and the annual dinner.

We are pleased to know that the Duke of Bedford has consented to occupy the chair at the sixty-first festival dinner of this association, to take place at the Whitehall Rooms on May 18 next.

Veronica spicata. The term "spicata," as applied to a *Veronica*, is not particularly determinate, hence it is not surprising to find in trade catalogues that an illustration of *V. longifolia* usually does duty for *V. spicata*; and so does the plant. The difference between the two, however, is well marked. *V. spicata* is really a dwarf, evergreen, slowly-creeping plant with somewhat broad dark green leaves, whence arises a stout spike of blue flowers in summer. It can be readily increased by division, as the stems root as they grow, and makes a good edging plant, always neat and tidy. It seems to me to do best where it can get a rather moist soil. T. J. W.

Leucopogon lanceolatus. In the days when hard-wooded plants were more generally grown than they are at present, this *Leucopogon* figured among the popular members of this class, but now it is rarely seen, though when in good condition it is a charming little greenhouse shrub. It forms a freely-branched bush, clothed with bright green lanceolate leaves, while the little pure white blossoms are borne in nodding racemes, and in such numbers that the plant is quite veiled with them. This *Leucopogon* is nearly related to the *Epacris*, and needs much the same treatment. It forms effective little flowering specimens in pots 5 inches or 6 inches in diameter. T.

Seeds of Crinum pensense. In the issue of THE GARDEN for January 6 I read the short note by Mr. Thompson, of Ipswich, on his experience with the seeds of *Crinum pensense*. This interested me the more, as but a short time previously I had read the similar experience that had come under the notice of Dean Herbert, an account of which was set out at some length by him in his letter on "The Production of Hybrid Vegetables," in the fourth volume of the Transactions of the Horticultural Society. In this he mentions that the seed capsule gathered from a

bulb of *Panercatium amboinense* which he had given to Lord Milton on being opened by that nobleman's botanic gardener was found to contain perfect turgidated bulbs. Dean Herbert said he greatly regretted not having had the opportunity of opening the capsule himself, as he suspected the bulbs to have been attached to withered seeds that had sprouted prematurely in the capsule. He mentions also that one of these little bulbs before it had sprouted produced within the outer coat an offset as big as itself, or rather it had divided itself into twin bulbs of equal size. Mr. Thompson does not mention whether the small bulbs were contained in the capsules or whether they were growing with the old seeds attached, there being some interest on this point, as Lord Milton's gardener was very positive that there was no other body in the seed-vessel.—REGINALD R. CORY, *Duffry, near Cardiff.*

Notes from Baden-Baden. Winter has passed mildly, but mostly sunless, dull, and rainy; in consequence bulbs in and outside have not done so well as usual. Nevertheless, *Crocus Boryi*, *C. marathonicus* and *C. atticus* began to show their buds in November, and readily opened after a glimpse of an hour's sunlight. The flowers of the first are pale lilac, feathered with violet-red, those of the second are large and pure white, and those of the last are bright blue, shaded red. All three are best kept either in a frame or in pots to adorn the greenhouse. Since December *Galanthus Whittallii* has been in bloom; it seems a very robust species which stands the inclemency of the season. Now the loveliest of bulbous Irises opens its buds; it is most likely a new species or a very distinct variety of *T. histrioides*; the flowers are large, of a pure satiny white adorned by an orange-yellow crest. Now also begins the blooming period of *Cyclamen libanoticum*. I beg to draw the attention of specialists to this new species, which, besides other qualities, is also hardier than persicum. I am convinced that, by cultural evolution, after a few generations *libanoticum* is likely to supersede or at least rival *C. persicum*, my conviction being based on the comparison of the flowering or collected wild bulbs of both species. The heart-shaped, comparatively large leaves of *libanoticum* are of a glossy blackish green, broken by a well-defined greyish zone; the flowers are very broad in shape and variable in colour, from white to deep rose, with crimson blotches on each of the segments. MAX LECHTLIN, *Baden-Baden.*

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

UNEXPECTEDLY, the frosty weather prevented many would-be exhibitors from bringing their flowers to the first February meeting of the society. Usually the exhibition at the Drill Hall on the occasion of the annual meeting is one of the most interesting of the whole series, but in spite of weather trials there was a good display, as the following report testifies.

FLORAL COMMITTEE.

A large and very effective group of the stellate form of the Chinese *Primula* was exhibited by Messrs. Cunnell and Sons, Swanley, Kent. The collection was awarded a silver Flora medal; it contained several varieties, among which were Miss Irene, rose; Purple Star; Lady E. Dyke, having pretty white flowers and bright green leaves; Mrs. H. Cunnell, also pure white; Queen of Roses; and Princess Eva, almost white, but with a slight tinge of pink.

A bright and pleasing show of colour was made by a group of Persian *Cyclamens* belonging to Mr. John May, St. Margaret's, Twickenham. The plants were splendidly flowered and the individual blooms exceptionally fine. This group also obtained a silver Flora medal.

Another pretty group was that of the useful evergreen greenhouse *Clematises*, *C. indivisa* and *C. indivisa lobata*, which won a silver Flora medal. The plants were in pots. We have never seen a more charming display of this climber, and such a display should increase its popularity for pot culture. One usually finds that the plant is grown simply as a climber. Shown by Messrs. William Paul and Son, Waltham Cross.

A silver Banksian medal went to Messrs. John Laing and Sons, Forest Hill, S.E., for an excellent display. It included a variety of foliage plants, *Crocus Webbiana*, some fine *Lilies of the Valley*, *Azaleas*, &c.

Messrs. Barr and Sons, King Street, Covent Garden, staged a small group of miscellaneous plants, among which were *Lachenalia Garnet*; *Lachenalia pendula*, a red form; *Narcissus minutus*, the pretty *N. cyclaminus*, both the white and sulphur-yellow; Hoop Petticoat *Narcissus*; *Primula obconica grandiflora*, and *Galanthus Elwesii* var. *Whittallii*, figured in THE GARDEN for January 20.

Messrs. J. Veitch and Sons, Chelsea, were again the exhibitors of a stand of their pretty greenhouse *Rhododendron* hybrids, showing a variety of delicate tints.

Two plants each of *Astilbe* W. E. Gladstone and *Astilbe* H. Whittier were brought before the committee by Messrs. van Waveren and Kruijff, Haarlem, Holland.

Mr. William Smythe sent a small semi-double mauve zalea named *Mauve Queen*.

Colonel Platt, C.B., Cordinog, Llanfairfechan, North Wales (gardener, Mr. W. Coates), showed specimen blooms and leaves of Chinese *Primulas* Princess May, Lady Sarah Wilson, Red Stem Queen, all having large white blossoms, Lady Sarah Wilson being new; Cunnell's Pink and Improved Holborn Blue, of a somewhat deep colour. The committee requested that plants be sent.

Sir Trevor Lawrence, Bart., Burford, Dorking (gardener, Mr. Bain), sent trusses of bloom of *Begonia semperforens* *Boule de Neige*, white, and *Triomphe de Lorraine*, bright red, both semi-double. In this case also plants were asked for. We think these *Begonias* will create considerable interest; they are quite distinct and fresh in colour.

Three fine new *Camellias* were exhibited by Messrs. F. Sander and Co., St. Albans. They were *Lady Buller*, rose, and almost single; *Lady Roberts*, pink, edged with white; and *Lady White*, white with splashes of red; both the latter are semi-double.

Mr. William Bull, 536, King's Road, Chelsea, showed specimen blooms of his strain of Chinese *Primulas*, including the new *Blushing Beauty*, a pink, semi-double form, and *Duke of York*, deep crimson.

ORCHID COMMITTEE.

Mr. R. E. White, Ardarauch, sent several good cut racemes of *Odontoglossums*, including *O. crispum*, *O. Histro*, three fine spikes of *O. Andersonianum* and a variety of *O. triumphans*, which resembled to a great extent the natural hybrid *O. excellens*.

Captain Holford, Westonbirt, Tetbury, Gloucester, sent a remarkably good form of *Cattleya Trianae*, *Cypripedium Calypso* Oakwood variety (a superior form of *C. nitens* variety), and *Mons. de Carthe*.

Mr. C. J. Lucas, of Warham Court, sent *Dendrobium macrophyllum* *Richardii*, a somewhat distinct variety of this shy-flowering species, to which a botanical certificate was awarded. The sepals are pale green, the petals yellow, the lip green, spotted with brown on the front lobe, lined with brown on the side lobes.

Mr. F. A. Rehder sent *Cypripedium Favarger*, a hybrid raised from the intercrossing of *C. Charlesworthii* and *C. concinnum*. The dorsal sepal is white, suffused with rose at the top, deep brown at the base; the petals greenish yellow, suffused with brown; the highly-polished lip deep brown, shading to green at the base.

Mr. W. Cobb, Dulcote, Tunbridge Wells, sent a fine form of *C. nitens*, *Laelia anceps*, *Stella*, and *L. Sanderiana*, each with five flowers on the raceme.

Mr. Chas. Maron sent *Laelia-Cattleya Ernestii* var. *pallida*. The sepals and petals yellow; the lip yellow, veined with maroon. It was derived from the intercrossing of *Laelia flava* and *Cattleya Percivaliana*.

Mr. E. W. Moore, Glasnevin, was awarded a botanical certificate for a cut raceme of *Zygopetalum Murrayanum*, a curious variety with green and white flowers.

Mr. J. Gurney Fowler, South Woodford, sent cut flowers of *Cattleya Trianae* (Glebelands variety), the flower having a very bright-coloured lip; *Laelia-Cattleya Miranda* (*Trianae* × *guttata* Prizii), with a five-flowered raceme, showing the intermediate characters of the parents; *Cypripedium woodfordense* (*Chamberlainianum* × *beechense*) and *C. Chamberlainianum*, showing the influence of the parents indicated in the name.

Messrs. Heath and Son, Cheltenham, sent a pan of finely-flowered plants of *Dendrobium barbatulum*.

L'Horticole Coloniale sent a grand form of *Odontoglossum crispum*, a finely-spotted *Odontoglossum Ruckeraeanum*, and *Cypripedium Schusterianum* (*villosum* × *volonteanum*). The influence of the combined parentage is most pronounced in the offspring, the yellow of *C. villosum* being particularly prominent.

Mr. N. Cookson sent *Calanthe Sybil*, pure white; *C. Phoebe*, bright pink; and the remarkable *Odontoglossum crispum* *Cooksonii*, with white and purple-spotted flowers of fine shape and substance measuring 4 inches in diameter.

FRUIT COMMITTEE.

The chief features before this committee were the two very fine collections of Apples from Kent and Herefordshire and a splendid exhibit of Rhubarb, Seakale, and Asparagus from Twickenham. A good number of seedling Apples were also shown, but all failed to get an award.

An award of merit was awarded to Rhubarb *Daw's Champagne*. This variety has a very good stalk, and is the result of crossing *Victoria* with *Hawke's Champagne*. It is earlier than the last-named excellent variety, is of better colour, and larger. This valuable forcing Rhubarb was sent by Mr. W. Poupert, Marsh Farm, Twickenham.

Messrs. G. Bunyard & Co., Maidstone, exhibited 100 varieties of Apples, all excellent as regards size and variety. There were some splendid cooking kinds. Mention must be made of the Afriston and Stone's, very fine dishes also of New Hawthornden, Annie Elizabeth, Peasgood's Nonsuch, Bismarck, Lane's Prince Albert, Royal Jubilee (an Apple well worth extended culture), and Mère de Ménage, the latter being highly coloured. There were also some grand dessert fruits, these being perfect in shape and colour. Among them were several good russets, such as Egremont and Royal, the newer Mrs. Phillimore, Lord Burgley, the Mother Apple, Winter Pearmain, Winter Ribston, Golden Reimette, and others, well meriting the silver-gilt Knightian medal awarded.

From Mr. John Watkins, Pomona Farm Nurseries, Withington, Hereford, came such a collection of Apples as is rarely seen in the metropolis, as there were some beautiful local varieties well worth notice; and to the fruit grower this collection was most interesting, as it shows what a wealth of

really beautiful fruits we have in the western portion of the country. Out of a hundred varieties it is impossible to name many. In the dessert section the colour was superb, and there were splendid dishes of Stoke Edith Pippin, Cowarne Seedling, a beautiful fruit, Lord Rindlip, Frankins Golden Pearmain, Emily Child, and Napoleon. In the cooking class were beautifully coloured fruits of Lord Beaconsfield, Newton Wonder, Beauty of Kent, Rymer, Tyler's Kernel, Bramley's Seedling, Hollandbury, Nelson's Codlin, and others. A silver-gilt Knightian medal was deservedly awarded.

Mr. W. Pompart staged four varieties of Rhubarb, a splendid example of culture, the varieties being Hawkes Champagne, the Victoria, Limons, and the new Daws Champagne, given an award of merit. He also sent some splendid heads of Senkale and Asparagus. A silver Knightian medal was given to this collection.

Some excellent Asparagus was staged by Mr. F. W. Campion, Reigate, in two varieties, Conover's Colossal and a newer kind, Sutton's Perfection.

A new seedling Apple, Melndoe's Russet was sent by Messrs. Veitch, Ltd., Chelsea. It is a New Zealand fruit, and of great merit on account of its good keeping qualities.

From Messrs. Lane & Son, Berkhamsted, came also a new Apple, a sport from the old Blenheim Orange, excellent in quality and quite distinct, being of a deep red colour. This just missed an award, some of the committee thinking it resembled the parent too closely.

The Duchess of Cleveland (gardener, Mr. Camio), Battle Abbey, Sussex, sent excellent Apples under the name of Sturmer Pippin, but they were thought to be Lord Banghley.

A new seedling Apple named Aurora, a pretty small dessert variety, was sent by Mr. W. Bull, Ramsden, Essex.

Apple Nancy Jackson was sent by Mr. Geo. Holmes, Acomb, Yorks. This is a favourite north country fruit, and an excellent cooker and keeper.

Mr. P. Crowley sent Quince jelly to show its value as a preserve. It was of excellent quality and good colour.

A hearty vote of thanks to the chairman (Mr. P. Crowley) for his services to this committee during the past year was proposed and suitably responded to, and he also thanked the members for their kindness and assistance.

ANNUAL MEETING.

There was a large attendance at the annual meeting on Tuesday, and it was certainly the most interesting and pleasant gathering that has been held for many years. The president (Sir Trevor Lawrence, Bart.) was in the chair, and near him were Sir John T. D. Llewelyn, Bart., M.P., Mr. J. T. Bennett-Poe, Mr. F. Du Cane Godman, F.R.S., Mr. T. E. Hayward, Mr. Frederick Lloyd, Mr. R. McLachlan, F.R.S., Dr. Müller, Mr. A. H. Pearson, Mr. Charles E. Shea, and the Rev. W. Wilks.

The minutes of the previous meeting having been read and confirmed and candidates elected, Mr. Bunyard said the best thanks of the members were due to the retiring members of council, and he mentioned that one had kindly consented to act again, namely, Sir John T. D. Llewelyn, Bart., who through many years has proved a true friend to the society. Sir Trevor Lawrence, Bart., the president, then reviewed the work of the past year set forth in the annual report. He first alluded to the completion of the catalogue of the Lindley library, and that the books are now encased in glass covers, which is, of course, in London in particular, a great gain, and referred to the part played by Mr. Elwes in making this change. Mr. Elwes had promised a valuable addition to the library if the books were protected. Sir Trevor incidentally mentioned that he knew the Fellows would sympathise with Mr. Elwes in his anxiety concerning his only son severely wounded in the war. There was a growing demand, he said, for gardeners who possessed a sound practical and scientific knowledge. The shows at the Drill Hall had fully maintained their character, and the exhibition that day would have been of greater extent if the weather had not been so unpropitious. The chairman referred to the new plants, fruits, and vegetables shown at the meetings, and that many plants almost new, so rare had they become, were exhibited, and displayed signal excellence of culture. A large number of awards was given, and the various committees devoted much labour to the work of adjudication, coming frequently from long distances to be present. Sir Trevor Lawrence said the warmest thanks of the society must be given to the members.

Reference was made to the Temple show and the demand for space, but the chairman said that the benches considered that sufficient tent room was provided according to the size of the gardens.

Then mention was made of Mr. Wright's good work at Chiswick and amongst the young men there, and this called forth considerable applause from the audience. The hybridisation conference was alluded to, and in feeling terms the chairman referred to the death of M. Henry de Vilmore.

Sir Trevor Lawrence Bt., hoped the Fellows would make up the £100 required to be raised by subscription to continue the fruit show at the Crystal Palace. The examinations, he said, help young men to further endeavours, and said that the possession of one of the society's certificates was of great assistance to a young man in obtaining a place. Then the new charter was touched upon, and it is interesting to know that now retiring members of the council can be re-elected the same year. The bye-laws must be drafted, and the work had been confided to a special committee.

We should have mentioned previously that the labours of the committee dealing with Orchids received warm praise. The centenary was approaching, and such matters as the new garden were touched upon. A garden had become necessary, as Chiswick was now surrounded by houses. The new garden must be within reasonable distance of London, with proper soil, water supply, etc.

Sir Trevor Lawrence then said that this was the only Western European country without a school of horticulture, and thought, with co-operation from county councils, it was a work the Royal Horticultural Society could pursue.

The financial position of the society was satisfactory, there

being a surplus this year of £1764, the largest that there has ever been in its history. The chairman paid a hearty tribute to the Rev. W. Wilks' good work, to the treasurer, Mr. Philip Crowley, and others.

Professor Henslow moved the adoption of the report, and spoke of Mr. Wright's good work and kindly consideration at Chiswick. He said he was gratified with the success of the lectures he had given to the young men last winter, and hoped to again speak to them next season.

Mr. Cheal was pleased to know the society was prospering, and hoped that an opportunity would be given for discussing the bye-laws before they were passed. He drew attention to the sum of £47 for Orchid pictures.

Mr. Geo. Paul said he hoped the new garden would be freehold, and Sir Trevor Lawrence said that it was the intention of the council to obtain the ground under this condition.

Mr. E. Dean also spoke, and Mr. Cheal proposed that a hearty vote of thanks be given to the president. The report was a splendid record, and the Fellows should feel grateful to the president. In reply, Sir Trevor Lawrence heartily thanked the members for their kind vote of thanks, and said that the council and the Rev. W. Wilks deserved unstinted praise for the work they had performed.

The vacancies of retiring members of the council were filled by appointing Mr. E. Du Cane Godman, F.R.S., Sir John Llewelyn, Bt., and Mr. Arthur J. Sutton.

Mr. Bunyard moved, and Mr. Geo. Paul seconded, that a vote of congratulation be sent to Sir Michael Foster upon his election as M.P. for the London University.

[Novelties certificated or given awards of merit at the Royal Horticultural Society's meetings are described under "New and Rare Plants."]

HORTICULTURAL CLUB.

A DELIGHTFUL evening was spent on Tuesday last at the Horticultural Club. It was the occasion of the annual dinner. Sir John Llewelyn, Bart., occupied the chair, and we were pleased to see the Rev. H. Honywood D'Unbrain present also. Several speeches were made, relieved with music. Mr. Bunyard was responsible for the arrangements of the dinner and music.

CARDIFF GARDENERS' ASSOCIATION.

ON Tuesday, February 6, Mr. T. Malpass gave an extensive lecture on the use of the Begonia for decorative and bedding purposes before the members of this association. Mr. H. Farmer occupied the chair. The debate was of a lengthy character, and many hints were thrown out as to a safeguard to rust and yellow thrips.

AUTUMN SHOW OF THE ROYAL CALEDONIAN SOCIETY.

THIS will be held in the Waverley Market on September 12 and 13, 1900, and there is little doubt that it will prove a great success. There are 261 classes in the schedule, with prize-money to the amount of £381. A large fruit class should prove interesting; it is for the best decorated table of dessert fruit, 10 feet by 4 feet 6 inches, 16 dishes of fruit to be staged, the kinds being Melons, Grapes, Apples, Nectarines, Peaches, Pears, Apricots, Figs, Plums, Cherries, and Strawberries. The prizes presented by the Corporation of the City of Edinburgh are £7, £5, and £3, for first, second, and third prizes respectively.

BRISTOL AND DISTRICT GARDENERS' ASSOCIATION.

THE fortnightly meeting of this society was held at St. John's Parish Room, Redland, on Thursday, 8th inst. Mr. W. Graves presiding over a good attendance. Mr. Rogers, of Stapleton Hill, supplied the paper, which was on the subject of tuberos Begonias. Dealing with the culture of the plant, he said seed should be sown in January in a temperature of 60 to 70°, pricked off as soon as possible, and kept potted as growth proceeded. The soil recommended for all purposes was loam, leaf-mould, and sand. For the greenhouse the plants should be kept in a light house and as near the glass as possible, a damp atmosphere being the best for them. Mr. Rogers strongly urged the use of Begonias for bedding purposes, and gave much valuable information regarding the culture for this purpose. A good discussion followed, and Mr. Rogers was accorded hearty thanks for his attendance. Prizes for Orchids in bloom were awarded to Messrs. Bannister and Newberry, and a certificate of merit to Mr. Maddock for a well-grown pan of Cyclamen.

ENGLISH ARBORICULTURAL SOCIETY.

WE have received from the secretary, Mr. John Davidson, part 2, vol. iv., of the transactions of this society. It forms a volume of considerable interest and importance, and contains accounts of the annual general meeting held in August last, excursions to English gardens. "The Pruning of Trees," by Mr. H. C. Lock, of Perth, and Mr. W. Forgan, of Alhwick; "The Different Kinds of Fences (Dead and Alive), their Cost, and the most Suitable Place for each kind of Fence," by Thos. Bewick, Ravensworth; "The Preparation of Land for an Estate Nursery, and the steps to be taken in starting the same," by Wm. Forbes, Swinton; "Notes on Larix leptolepsis," by J. R. Brown, Atrincham; "The English Arboricultural Society's recent Excursion to London and Neighbourhood: What was seen, and what advantages the members derived therefrom," by J. Ed. Dalgleish, Bishop Auckland; "Scale Insects," by A. T. Gillanders, Alhwick; notes and comments, subjects for essays for the present year and various other details. The book is illustrated. There are views of the Rock Garden, Kew; of the River Thames, from Richmond Hill; of the Terrace, Richmond; of Windsor Castle, East Front; The Long Walk, Windsor; the illustrations being of the places visited by the association.

COMMONS AND FOOTPATHS PRESERVATION SOCIETY.

AT the usual monthly meeting of the Commons and Footpaths Preservation Society, recently held at 4, Great College Street, Westminster, the Rt. Hon. G. J. Shaw Lefevre presiding, the report of the society's solicitor, Mr. Percival

Birkett, on the private Bills to be dealt with by Parliament during the current session was considered. It appeared that 42 Bills come within the purview of the society, which in the aggregate threaten to absorb nearly 3000 acres of common land and a large number of rights-of-way.

Among other Bills to which exception was taken by the society, and which it was resolved to vigorously oppose, in the event of satisfactory terms in the public interests not being forthcoming, are the Huntingdon Corporation Bill and the Hoylake and West Kirby Improvement Bill. Under the former Bill power is sought by the Huntingdon Corporation to deal with 336 acres of common land in its area. Of this large extent of open space it is proposed to allot only 10½ acres for the purposes of a public park, the remaining land to be sold, let on building leases and otherwise dealt with. This Bill was felt by the society to be a serious attempt to avoid the machinery constituted by Parliament under the Commons Act, 1876, for the safeguarding of public interests, and it was unanimously resolved on the motion of Sir John Brunner, Bart., M.P., to oppose the Bill in Parliament. The society also determined to oppose in its present form the Hoylake and West Kirby Improvement Bill, on the ground that its provisions are likewise contrary to the principle of the Commons Act. It is proposed under the Bill to allot about 108 acres of the common lands in the Manor of Great Meods to the persons legally interested in the land for building and other purposes. A further 88 acres of land would be devoted to recreation grounds and the provision of public streets, while 45 acres (partly reclaimed) would be developed to defray the cost of the construction of a sea-wall.

Exception was also taken to provisions in the Great Northern Railway and London County Council (General Powers) Bills. The former Bill proposes to give the company power to absorb 42 acres of Hexthorpe Ings, Doncaster, and under the latter Bill, an effort is being made to enable the Battersea vestry to deal with 11 acres of allotment land set out under an Inclosure Act (4 & 2 Will. IV., cap. 42). Part of the land is to be utilised for workmen's dwellings. In 1888 the Battersea vestry promoted a Bill to enable it to build on the land, but in face of the strong public opposition evoked, the Bill was withdrawn.

Amongst the water-schemes proposing to deal with common land are the East London Water, Exmouth and District Water, Paignton Urban District Water, and the London Water (Welsh supply) Bills. These affect over 1700 acres of common land, and the society determined to endeavour to secure the insertion of clauses in the Bills to give the public a right of recreation over the large catchwater areas which it is sought to establish on the commons involved.

THE ROYAL SCOTTISH ARBORICULTURAL SOCIETY.

THE annual meeting was held at No. 5, St. Andrews Square, Edinburgh, on the last day of January, the Earl of Mansfield, the president of the society, in the chair. There was an excellent attendance, and the routine business consisted of the re-election of office bearers, presidents, vice-presidents, council, secretary, treasurer, auditor, honorary scientists, and local secretaries. Votes of thanks and of sympathy by Mr. Mackenzie were proposed for lost members, especially the Marchioness of Lottian. It was then decided not to visit France this year as was intended, but that the excursion should be to Ayrshire or the north. Also that the promised international forestry exhibition in Glasgow in 1901 should not be held. Then two additional orders of members were established, the first to be called honorary associate members to have all publications gratis and pay no subscription; the second, that on the recommendation of the University lecturer, the senior student of the University class on forestry shall be made an honorary associate member. This is to have effect for five years from January 1, 1899.

A motion by Mr. George Fraser, factor, Dalzell, Motherwell, that at all general meetings of the society the members shall be entitled to vote by proxy, was opposed by the council and defeated by vote, with 25 against and 6 for. The council's and also the treasurer's reports were adopted, showing a credit balance on the capital account of £154 15s. 6d., and on the revenue account £130 0s. 0d. Since the close of the year the society had invested £200 of this sum in the Caledonian Railway Company. The death-rate of the society had been heavy during the year, but they had gained many others. At their last meeting the total membership was 892, of which 612 were ordinary members. At the present time there were 834 on the roll, 32 having been admitted during the year.

The Earl of Mansfield then gave a most suggestive and practical address on the training of young foresters; this was in brief to adopt the three years' apprentice system that had proved so effective in rearing good gardeners. He also recommended the better housing of foresters in lodges for fellowship and educational and social stimulus, likewise some training in farm work and the establishment of a registry for foresters, so that they might feel that they belonged to an independent profession.

As Lord Mansfield's curriculum may prove most useful to other landlords, we have pleasure in giving it here:

First year. Instruction in the home nursery, so as to make himself familiar with the different varieties of trees, their propagation and general treatment.

Second year. Instruction in the formation of plantations and their management, including fencing, hedge treatment, rough carpentering, and perhaps road making and bridging.

Third year. Learn something of the felling and management of timber, value of standing and fallen timber, and also the working and management of sawmills. Arrangements might also be made for retaining the apprentices as journey-men or foremen foresters on the same or other estates.

After some remarks by Mr. J. R. Mackenzie, W.S., on the relation between the forester and the gamekeeper, on the motion of Mr. Alexander Milne a vote of thanks was passed to the Earl of Mansfield. Dr. Nisbet, F.L.S., followed with a most interesting and instructive address on the present condition and future prospects of forestry in Britain. The subject at best had received but scant and spasmodic attention. Gracefully advertising to the assistance given by the

society, he went on to contend that the £18,000,000 worth of coniferous wood annually imported into this country could easily be grown in different parts of the British Isles. He then went on to show that the exhaustion of the forests of Germany and the United States were threatening. British supplies from Canada and the Baltic. The days of cheap timber in Britain were nearly at an end. Characterising British woodlands in the language of Sir Herbert Maxwell as largely pleasure grounds and game covers, he condemned dense planting and injudicious thinning. Woods to pay must be managed on some far-reaching plan. The rating of woodlands might also be lowered or abolished, and money lent at cheap rates for extensive afforestation.

Mr. James Kay, of Bute, followed, with a pithy paper on the afforestation of waste places of the country, and suggested that some of the spare time of our soldiers might be turned in this direction to the improvement of the physique of our troops, the securing of more and better recruits from the rural districts than the towns, and doing something to link more of the rural population to the land through bettering the condition of the common soldier.

The members of the society dined together in the Royal British Hotel in the evening, Lord Mansfield in the chair. After the usual loyal toasts, Mr. James Macdonald, the secretary of the Highland and Agricultural Society, proposed the toast of the Royal Scottish Agricultural Society, and in doing so adverted to the connection between forestry and agriculture, and hoped that more attention would be given to forestry in the future. The chairman, in responding, referred to two things that he found so common: profound ignorance of the society and great admiration for it. He invited all to come near enough to become useful members and render them some help at close quarters.

The Master of the Merchant Company, Mr. John Macmillan, submitting the toast of "Forestry Instruction," spoke of the necessity of improved forestry as a matter of national importance. He mentioned that the percentage of the average of the country under forest was smaller in Britain than any country in Europe, not excepting Holland and Denmark. "The small state of Belgium, with the densest population of Europe, had a forestry area of nearly five times greater in extent than this country. Dr. Nisbet, in reply, noted what was being done by the Indian Government, and observed that the failure of crops and constant famines in that country were to a certain extent due to the devastation and clearance of national forests to an extent almost beyond the power of man to replace. He strongly advocated the institution of a chair of forestry in the country, and appealed to the Merchant Company to assist the society in this direction.

Professor Bayley Bolton, professor of the Royal Botanic Gardens, Edinburgh, proposed the health of the president, and other toasts followed, and the forty-seventh annual meeting of the society proved one of the most pleasant and profitable that has yet been held.

Index and Editorial Notices will be found amongst the advertisements.

ANSWERS TO CORRESPONDENTS.

Names of plants. A. Y. Z. I. Begonia Arthur Malei; 2. B. nitida; 3. B. corallina; 4. B. Carrieri villosa; 5. B. Gloire de Semeur; 6. B. argenteo-guttata; 7. Maranta Makoyana. S. W. W. Probably a seedling form in the way of Cupressus Lawsoniana argentea.

KITCHEN GARDEN.

Peas (R. C.). So much depends upon your requirements. For earliest supplies sow early in March such kinds as Bonitaful, Bony or Boston, Unrivaled, these will mature in June. For July use sow at the end of March Shraples Queen, Stratagem, Dr. Maclean or Telephone. For August sow in April at the middle of the month Antocrat or Peedless Marrowfat or any strong growing Marrow variety. For later supplies sow in May and June such kinds as Ne plus Ultra, Windsor Castle, or the Michaelmas Pea. Any of the varieties named sown as advised are reliable.

Early Radishes (J. J.). Very many persons like yourself ask, and naturally so, why, seeing the Early Olive or French Breakfast Radishes looking so lovely in colour and so fresh and crisp in the shops, they cannot also have such in their own gardens. It is easy to do so, as seed is always readily obtainable and cheap. But still, it is all a matter of culture. Place a frame on the soil in a warm border, then throw into it several barrowloads of short, well-mixed stable manure, and level it and tread it down; then strew 2 inches of good fine soil over the surface, sow the seed thickly, and water it. Then, shutting the frame close and covering it up for a few days, the warmth generated in the manure will soon germinate the seed and in about eight days the soil should be thick with plants. Remove the covering and give a little air behind. One other watering may be needed, but in any case there should be plenty of Radishes to pull in about six weeks. If you cannot spare a frame, make a bed outdoors by throwing out the soil 4 inches deep, tilling up with manure and adding soil. Then sow the seed, water and cover it up until growth has begun. Even then give cover at night-time.

Peas for crop (ALFHY). The choice of good Peas is indeed great, for there are scores of good varieties in commerce, nearly all producing Peas of the best marrow quality. We certainly advise you to prefer those of medium height. That is, from 3 feet to 3 feet 6 inches to quite tall ones. Of these Peas of medium height, quite early ones are Gadus, May Queen and Bonitaful, then follow Senator, Magnum Bonum, Peedless Triumph, the Queen and Antocrat. This is really a first-rate selection, coming in in the above order. Peas of this height should be sown in drills fully 3 feet apart and quite

thinly. A quarter of a pint should sow a drill of from 20 feet to 25 feet. This comparative thinness enables the plants to branch as they grow, and they crop longer. Your first sowing of one of the earliest should be made at once on a warm border, the others following in succession once a fortnight.

FLOWER GARDEN.

Seeds of Mistletoe. "Medway, The Grange, Bromden, Cranbrook, asks if some reader of THE GARDEN would be so good as to send him a few Mistletoe berries when fully ripe for sowing.

Sowing Poppies in turf. "K. S. S. asks for advice about sowing Shirley Poppies on a piece of rough lawn. It is not usual to sow Poppies in turf, and we are doubtful whether they will do much if sown among grass already established, although they would be likely to thrive if sown with grass seed on ground otherwise bare. However, to answer the question as nearly as we can, the best way would be to lightly scratch the turf with a rake and sow the seed very thinly broadcast and then to roll the turf. This should be done in the end of August, or beginning of September at latest. The Shirley Poppies, being the most nearly related to the wild field Poppy of all our garden kinds, would be more likely to succeed than any others.

Lawn weeds (GLOSTER). Only persistent extracting weeds from a lawn will keep them down, but the work wants to be done methodically. The proper course is to strain a line across a portion of the lawn, marking off a width of 3 feet; then employ a sturdy woman or girl for they usually do the work better than lads armed with a weed fork and a basket, to begin at one end and clear all the weeds from the yard width. When that is cleared, then clear another yard, and so on until the entire lawn is done. Then topdress with fine soil, well raking it in, and roll frequently. The grass will soon grow over and fill the vacancies created by pulling the weeds. These pests usually give most trouble in dry weather, when the grass is less strong.

Primroses sowing seed (J. S. C.). By the term Primrose we assume you mean all those grown in gardens. Polyanthus as well as Primroses, as all need the same treatment. In ordinary good garden soil and during a fairly moist season it is sufficient to sow seeds outdoors in April or May keeping it just damp and shading until there is good growth. But in the case of choice seed or where the quantity is small, we advise sowing it thinly in a shallow box or pan filled with soil, then if watered and stood in a frame or cold greenhouse and shaded from hot sunshine, good growth soon ensues. Such a sowing may be made in March, as then the plants have become strong by the end of May or early in June, and they may be carefully lifted and be transplanted where they are intended to flower. But the best plan of all is to get seed in August and sow it outdoors thinly about the last week of that month, and then, leaving the seedlings in the bed all the winter, to plant out in the spring.

Filling wire baskets (G. S.). The best time of the year to fill wire baskets that are intended for hanging out of doors during the summer is towards the latter part of April, as that will admit of their being kept for a few weeks in the greenhouse in order that the plants may become established before putting them outside. Some of the most useful plants for the purpose may be raised from seed, while others must be struck from cuttings. In the case of those increased by seed it should be sown sufficiently early to allow the young plants to become established in small pots before they are put in the baskets, as they then grow away without any check. The latter end of February or early in March is a good time to sow the seed, which in a warm greenhouse will quickly germinate. Plants that can be raised from seed include Petunias, especially the single-cusped and semi-double varieties. These will flower throughout the entire summer, and if attended to will yield an enormous quantity of bloom. Topodoliums of different kinds may have much the same end of them, except that the middle of March will be early enough to sow seeds of these, as they germinate in a few days and quickly make headway. *Thunbergia alata* is an annual plant of a climbing or drooping habit. There are several varieties of this varying somewhat from each other in the colour of the flower. The showiest is that of a rich orange-yellow with a purplish brown throat. Seed of this is readily obtainable. Lobelias when raised from seeds are often of a loose style of growth, and for hanging baskets they are just the thing. Plants that are propagated from cuttings and kept during the winter in the greenhouse are Ivy-leaved Pelargoniums, which are surpassed by no other plant for hanging baskets. There are several varieties, all of which are very beautiful, but however limited the selection, Madame Grosse, salmon-pink, and Souvenir de Charles Turner, carmine, must be included. Pelargoniums of the zonal-leaved section, though they are wanting in the grace and elegance of the Ivy-leaved varieties, will flower well under such conditions. Some of the looser growing Fuchsias readily lend themselves to this treatment, while tuberos-rooted Begonias, not little seedling mites, but those that flowered last year will make a good display in baskets. Some of the Campanulas, particularly *C. isophylla* and its variety *alba*, are now very popular basket plants, and in their way hard to beat. The Creeeping Jenny (*Lysimachia Nummularia*) will yield a wealth of its golden blossoms throughout the entire summer. In planting these large wire baskets they should be first of all thoroughly lined, if possible, with large closely woven flakes of moss, which are in some districts readily obtainable. Failing this, thin turves with the grassy side outwards may be employed, and the plants disposed at will therein. The soil used should be moderately rough, as if fine it is apt to make its way through any spaces that may exist and be washed off when the baskets are watered. A few flakes of moss pegged on the surface will do much to obviate this. Watering must throughout the summer be carefully attended to, as upon this to a great extent depends the display of bloom. T.

INDOOR GARDEN.

Climbers for greenhouse (C. C.). The climbers must be planted in a border inside the house, as by so doing they are rendered safe during severe frost. A width of a yard is very suitable for the border, and the soil should be taken out to a depth of 2 feet. Six or 8 inches of drainage material, such as old bricks, rubble, and broken pots, must be put in the bottom, and if possible over this a layer of turves, on which the remaining soil should be placed and trodden down moderately firm. By making a border in this careful manner its permanent success is ensured, and a little extra trouble in preparing it is time well spent. As your hot-water pipes are so near the front wall, there is not room to train up the climbers between the two, in which case they may be planted 6 inches from the pipes inside the house and carried up direct to the rafters that they are to furnish. Though most climbers are vigorous rooting subjects, and will require a good amount of water when once established and growing freely, yet care must be taken that they are not kept too wet, otherwise the soil will become sour before the roots have taken possession of it. A good half-dozen climbers for the purpose indicated, omitting Passifloras and Lapagerias, which last would be scarcely likely to succeed under such conditions, are: Clematis *indivisa*, white, February and March; *Golga scandens*, purplish, summer and autumn; *Kennedia Maritima*, scarlet, February to May; *Solanum jasminoides*, white, nearly all the year round; *Taesonja van Volxemi*, magenta-scarlet, summer; and *Tecoma jasminoides*, white with purple throat, summer; besides the above selection, six very desirable subjects for training to a roof, which, though not strictly climbers, are of a loose rambling habit, are: *Abutilon Double de Neige*, whose white bell-shaped flowers are borne from the early part of the summer till the end of the autumn; *Abutilon Golden Flere*, a counterpart of this last, but with yellow flowers; *Fuchsia Monarch*, a fine bold dark colored flower; *Habenarium aurantiacum*, orange, autumn and winter; *Hadrothamnus elegans*, crimson, much the same time; and *Plumbago capensis*, a charming plant, which throughout the summer bears a great profusion of clusters of light blue blossoms.

APOLOGY.

TO MESSRS. SUTTON & SONS, Seedsmen, Reading.

GENTLEMEN. We extremely regret that in our catalogue we should have infringed the copyright of your "Amateur's Guide in Horticulture" by having used two of your original pictures of your vegetables and making use of paragraphs of your text.

We acknowledge that we have thus laid ourselves open to legal proceedings and a serious penalty, and we offer you our apology for what we have done. We also undertake that we will not in future infringe your copyrights, and we will forthwith surrender to you all catalogues or circulars in our possession containing prints of the blocks and paragraphs, together with negatives, negatives, and photographs of the illustrations complained of.

We desire to thank you for your generous treatment in not having taken legal proceedings against us to enforce your rights, and we authorise you to publish this letter in such a manner as you may think fit, and we engage to pay all the legal and other expenses you have been, or will be, put to in the matter.

Yours faithfully,
(Signed) PENNELL & SONS,
Seed Merchants and Nurserymen, Lincoln.
January 20, 1900.

APOLOGY.

TO MESSRS. SUTTON & SONS, Reading.

GENTLEMEN. I much regret I have infringed your copyright in two illustrations taken from your "Amateur's Guide," by making process blocks, engraving them with my name, and printing them in Messrs. Pennell's "Book of Seeds for 1900."

I wish to state that as I made the blocks from photographs supplied to me, the infringements were quite unintentional on my part.

I beg to offer you my apology, and at the same time my thanks for your consideration in refraining from enforcing your rights, and I authorise you to publish this acknowledgment in such manner as you may think fit.

Yours faithfully,
(Signed) W. HOLMES.

TRADE NOTES. APPLES FROM CANADA.

Canadian Apples are entering into serious competition with American fruit in the London market. Shipments during the month of January were particularly heavy, in one day 7524 barrels, containing 22,572 bushels, having been loaded. A fine variety of Newtown Pippin, hitherto exclusively obtained from American orchards, was among the importation. The culture of this variety in Canada promises more extensive shipments in the near future.

THE GARDEN.

No. 1475.—VOL. LVII.]

[FEBRUARY 24, 1900.

A SCHOOL FOR HORTICULTURE.

WE feel a sense of self-satisfaction in the knowledge that horticulture is to receive stronger support in the future than in the past; and if one ponders a moment, is it not discreditable that horticulture, pursued so ardently and successfully by the trade and private individuals, should have crept into the background as if ashamed to reveal its great power and importance amongst the business pursuits of this country?

There must be no hiding a brilliant light under the proverbial bushel in the future, and the good words spoken during the past few days should make the horticulturist think that it is time to act in support of the great industry in our midst.

We know the work that has been accomplished in the Chiswick gardens of the Royal Horticultural Society in forming the nucleus of a school for practical gardening. This foundation, laid, we believe, in a way unknowingly, should become a solid structure. Students have sought the historic gardens to commence their career without any great advertising of the benefits to be received there.

But under kindly and sympathetic superintendence this school has developed, and when the society enters into its new life amidst pleasanter surroundings, from this school will come forth young men with sound gardening knowledge to undertake horticultural duties at home and abroad.

We are not forgetful of the great work accomplished by the director of the Royal Gardens, Kew, in encouraging young men to make positions for themselves at home and in botanic gardens abroad, and this work will be even helped forward more strongly when the school of practical gardening provides a home apart from government supervision for training young men in horticulture.

It will be interesting to watch developments in the future, and those who assist to push forward this new departure may rest assured of our hearty co-operation. The school must be founded in a thoroughly business way, without fanciful conceptions of gardening, but with the firm conviction that practice and science must go hand in hand to fit the man for his work in life. Young men will enter this school to equip themselves for horticultural work at home and in our colonies, and examinations will doubtless take place, as at the present time, under some

authoritative governing board—may be the Royal Horticultural Society, or members of it.

The future is hopeful and full of possibilities, and the next few years should witness a remarkable change in the status, so to say, of horticulture in this land. The sister calling of agriculture has received far greater support than horticulture, but we feel that this will be altered in the near future with distinct advantage to the community.

Surprising ignorance exists even in these days of many of the elements of gardening, and of fruit and its culture our markets display an unpleasant reflection of the methods of the past. An awakening has taken place, and steady progress is preferable to hysterical upsetting of old customs. The school must be upon a sound basis, and for the advance of horticulture alone, with judicious assistance from more scientific pursuits. Horticulture cannot be mastered in a day, nor any branch of it. There are sufficient details in the cultivation of fruit to long occupy the earnest attention of the beginner, who must be drilled in every phase of the business, varieties to plant, their individual requirements, soils, and ways of managing the land to render it profitable over many years. There is only one way to accomplish this, and that is by educating public opinion to the advantages of a thorough horticultural training for those who follow this calling.

Horticulture in many ways is winning friends, and the English garden reflects an altered conception of this pursuit, now followed by many for its own sake, not at the dictates of the prevailing fashion. In the pleasure ground, in the woodland, by the lakeside and upon its surface flowers have their place, and are regarded as essential attributes to life's happiness. There is the other side—horticulture followed for the livelihood it brings, and this industry must excite as deep an interest as the pure enjoyment and knowledge of flowers. Competition in fruit and flower culture at home and through foreign importations must be faced, and the only way to do this is by training men in a school founded for this object.

ROYAL GARDENERS' ORPHAN FUND.

It is satisfactory to know that this fund—a children's fund—is progressing steadily, and this at a time when the purse-strings of the nation are untied for our soldiers at the front

But the gardeners of England must remember that the fund concerns themselves; it is a fund for the benefit of the children left at the mercy of the world when the bread-winner is called away. The annual meeting was held last Friday (February 16), and was a pleasant gathering of horticulturists, trade and otherwise, to help forward a thoroughly deserving institution. Whenever the committee is in the happy position of possessing a healthy report, the annual meeting reflects the satisfaction of the members. It was so on this occasion, for we are pleased to know that the receipts show an increase over those of the previous year of nearly £80, but the report says, "The revenue derived from subscriptions and donations, though showing an increase on the previous year, reveals a sensible decrease in the amount collected by local secretaries, a circumstance which the committee can only regard with some anxiety, though they have reason to believe that the falling off in this source of income is only temporary, the result being due rather to the difficulty experienced in collecting subscriptions than to any slackening of the efforts of those who have hitherto done so much in support of the fund. In common with most other charitable institutions, there is only too much reason to fear that the fund may suffer from the pressure of the times during the coming year, but the committee sincerely trust that the supporters of the institution will assist them to the uttermost in their efforts to avoid such a deplorable contingency. To maintain the usefulness of the fund unimpaired should be the aim of everyone interested in gardeners and gardening, and the committee more especially appeal to gardeners themselves to increase their efforts on its behalf by collecting small sums in their own districts."

We hope gardeners will help this fund, especially young gardeners, for to them it appeals more strongly than to men of advanced age. True, a large annual subscription is impossible, but a shilling a year surely is not too much to ask even from under-gardeners, and every shilling swells the revenue. Since the fund started only one child has died whilst receiving support, and the number of children upon the books is now eighty-two, thirteen having been elected at the last meeting. Since this fund was started, eleven years ago, £7111 2s. 6d. have been distributed among destitute orphans.

Many interesting particulars of the last annual meeting and of those who are working diligently for the fund are given in the usual department at the end of the paper. We give this brief outline here to place the claims of the fund conspicuously before all who are interested in gardens and their gardeners, and the gardeners themselves. It is only by united efforts that the committee are enabled to give relief to more children, and too often children are many, but funds few. It is hard to refuse relief to little destitute orphans, but without funds charity is impossible.

INDOOR GARDEN.

LACHENALIAS.

LACHENALIAS are making a brave show in several Norfolk gardens just now. Several good varieties have been raised in the county, two of the best being *Gunston Gem* and *Vicar of Causton*. Both at Blickling and Gunton these beautiful flowers are well grown, and are invaluable for cutting or for use in ornamental baskets in the drawing-room. Lachenalias frequently get rough-and-ready treatment, but no bulbous plant requires more careful culture. Good fibrous loam, a fifth part well rotted manure—cow manure is best—a sprinkling of leaf-mould, and sufficient sand to ensure porosity form a suitable compost. Mr. Allan pots his bulbs in August, placing ten in a 6-inch pot which is well drained. Good drainage is imperative, as Lachenalias are thirsty subjects when in vigorous growth. Popping completed, they are stood in a cold frame and protected from drenching rains. At the end of October they are placed in a house in a temperature of from 45 to 50, and afforded a position near the glass. The plants are fed with weak liquid manure, and during February and March produce freely the richly coloured flower-spikes. Lachenalias will stand gentle forcing well, but those that are forced one year should not be allowed to come on quite early the next. Careful drying off of the bulbs is an important point in their culture. After flowering, the supply of water must be gradually lessened—not entirely withheld all at once, as is sometimes the case—and in June the pots should be stood at the foot of a sunny wall in order that the bulbs may become thoroughly ripened. Some growers prefer to let the bulbs start into growth before re-potting them, while others equally successful in their culture pot them when dormant. *Lachenalia Nelsonii* is undoubtedly the finest variety in cultivation.

Frogmore, Windsor.

H. THOMAS.

A HEDGE-BANK GARDEN.

THE reason that one sees so few banks well treated is doubtless the difficulty of getting rid of the original inhabitants. I know some five or six banks that have been planted, and with the exception of two they are failures because of the way the Couch Grass and other weeds flourished in the soil put down for the newcomers. Personally I advise the partial pulling down of the bank and the entire removal of the old surface soil, and then a reconstruction on the Devonshire plan of alternate layers of stone and soil; a bank so treated is certain to succeed and is easy to keep clear of unwelcome intruders. The list of shrubs in last week's GARDEN cannot be bettered except that I should exclude the Elder, which has an unhappy knack of monopolising more space than it is meant to occupy, and under which many plants refuse to flourish and some to grow at all. But that is a matter of opinion, and, judging by the large number of the variegated Elder one sees around, it must have many admirers. One thing that should be planted extensively is *Jasminum nudiflorum*. Cuttings stuck into the side of the bank will strike and increase rapidly, and this plant when in bloom looks better with a green background than it does with that of a red-brick wall. Also in places where *Tropaeolum speciosum* will survive the winter out of doors, clumps of tubers should be planted in the soil with the shrubs, and in a little while they are sure to assert themselves.

I also have a few suggestions for the bank-sides. A good strain of *Honesty* should be planted in bold patches and it will soon sow itself perchance, too freely. The flowers in early summer and the seed-pods in autumn are at their best when the plant is grown in a semi-wild fashion. Again, the wild *Toadflax* should not be forgotten and will look after itself, and hard by there should be a clump or two of purple *Liatris*. The wild *Aquilegia* loves a bank, and the shady side suits it best, and it throws up heads of bloom and foliage far finer than when grown in the border. Care must be taken, however, to get seedlings of the right colours, and single above all things. The wild purple, pink, and white are far more beautiful than the hybrid washy colours, and even were the hybrids more beautiful they would be out of place growing in semi-wildness.

Speaking of washy colours as I have above, I of course refer only to the common forms; the hybrid spurred varieties in their many colours are amongst my favourite flowers, but they are unsuitable for bank planting. There are, however, many strains of the commoner forms in which the colouring of the spurred varieties has been borrowed, and much out of place it is on the more robust and less refined type. A few plants of various kinds of *Periwinkles* look well and soon cover a large space, and a few good clumps of *Lily of the Valley* often hold their own and run freely. With the addition of some patches of the wild *Arum* a bank would be well supplied with plants, and there would only remain bulbs to be considered. Of these I recommend plenty of single *Snowdrops* and a few good patches of *Snowflake*. I say a few because they do not always succeed.

Scilla nutans, pink, blue, and white, but in particular white, and *S. campambata* also should be planted in broad stretches, and would make a fine show in spring.

Thirdly, a few *Narcissi* should find a home. The best varieties for our purpose are the common double *Telamonius*, the wild *Lent Lily*, and the charming and once wild *obvallaris*. Thus planted a bank should succeed and be lovely through spring, summer, and autumn.

There still remains winter to think of. Some *Iris foetidissima* would give a bright patch of colour, and should be gay with its scarlet seed-pods until early spring, and if sweetness is wanted and the planter is not afraid of trouble in the future, he might plant some winter *Heliotrope*.

Newton Abbot.

GARDEN THOUGHTS.

WINTER THOUGHTS ON SUMMER FLOWERS.

"He who would have beautiful Roses in his garden, must have beautiful Roses in his heart."—DEAN HOLE.

WINTER is ever a time for reflection—a period when one can take a retrospect of the year's work; but it is not a time of inactivity, as a gardener's duties are never ended. Winter for him is a season of increased watchfulness. There is a hidden meaning underlying the almost proverbial words quoted above. One must not be content with merely admiring our Roses on the exhibition table, or blooming in the garden under the fairest of summer skies, but in the darkest period of the year, when to the casual observer there is no attraction in the garden, they must then be in our thoughts.

We must shelter the weakest from biting winds and long-continued cruel frosts; we must discern in them even now, under their most adverse conditions, the possibilities they possess of future beauty. Our most cherished Teas must be to us, at this unfavourable season, as charming in our mind's eye as when their first blossoms unfold. Thus, after tending, watching and pruning, when winter's storms are over and Nature has relaxed her grasp, they shall yield to the gentle influences of returning spring and again beautify.

But the quotation may be applied in a much wider sense, for he who truly loves his garden often reviews his favourite flowers. The June borders, so bright in their effulgence of blossoms, are "pictured" by the one who has planted them long before the first buds expand. To him the time of waiting is also a time of pleasurable anticipation. Perhaps no profession or pastime makes more claims upon one's thoughts than that of gardening, for to have gardens beautiful there must be exercise of forethought, trials of patience, and perchance at times lessons of failure; but through it all there must also be a steady plodding.

Each month in a garden or greenhouse there will be the allotted tasks of sowing and planting, of tending and watering; and just in so far as we have put our heart into the daily routine there will be an equivalent in the days that are to come, and the highest reward of our labour will be the abundance of ever-welcome flowers.

LEAHURST.

Deep cultivation of the soil. The discussion upon this subject has aroused considerable interest, but owing to pressure upon our space this week several contributions must be held over.

PRIMULA VERTICILLATA.

THIS greenhouse species of *Primula* from Abyssinia may be had in flower the following winter by sowing seed in the month of February. It is a most charming little plant, bearing whorls of yellow flowers, well thrown up above the pretty whitish-coloured leaves, in themselves very attractive. A suitable method of culture is, after the seed has germinated in a pan of light soil, to transfer four of the seedlings to a 4-inch pot, and allow them to remain there until flowers are produced. This number will be found to be quite sufficient to well fill the pots when the plants are fully grown. Very careful watering, a cool, shady pit, and plenty of room in which to properly develop are essentials to their successful treatment. The leaves are extremely liable to decay if either too much or too little water is applied. The soil dries quickly in hot weather, for with four of the *Primulas* in each pot it becomes full of roots. All flowers that appear during the growing season should be pinched off; none ought to be allowed to remain until winter it, as I am supposing, the plants are required for winter flowering.

Frogmore, Windsor.

H. THOMAS.

ERANTHEMUM PULCHELLUM.

NOTHING could be brighter or more attractive in the stove at the present time than the beautiful blue flowers of this acanthaceous plant. These are not only produced freely, but a long succession of them is maintained, two or three dozen plants furnishing a supply of flowers throughout the greater part of the winter months.

There is no difficulty connected with the cultivation of *E. pulchellum*. Cuttings of the young growths, produced from plants cut down after having flowered, are inserted several in a 4-inch pot, and the latter plunged in the stove propagating frame. When rooted, each plantlet is potted off into a 3-inch pot, using for the purpose a compost of loam, peat, and silver sand. If kept near to the glass in the stove throughout the

FRUIT GARDEN.

PEAR DURONDEAU, OR DE TONGRE.

THE fruit illustrated is usually known as Durondeau in this country, and it is a great favourite at all exhibitions on account of its large size and shape and free-bearing habit, even when grown in different soils and situations. This Pear is more at home in a warm soil and in southern counties, as I have seen heavy fruits in Devon and Cornwall. Many of my readers may have noticed the huge fruits of this variety grown in Jersey

THE DURONDEAU PEAR.

and those exhibited at the Crystal Palace fruit show last September by the Jersey Horticultural Society. There it was shown as De Tongre, and under this name it is largely grown in France. Many growers confuse this variety with Grosse Calebasse, a stewing Pear of less value, but an equally large fruit and not unlike it in many respects, being a long fruit much covered with grey-russet, whereas the De Tongre is a shorter fruit, more shining, and with streaks of dark crimson on the sunny side, yellow on the opposite, and covered with cinnamon russet.

This variety is in season early in October from a south wall, and from colder sites the fruits keep good well into November. It is

described in Dr. Hogg's "Fruit Manual" as a first-rate Pear, but no one can class it with Doyenné du Comice or Marie Louise, and I should certainly consider it second-rate, though by no means one of the worst in that section. During the past two seasons I have gathered splendid fruits, as regards flavour, from bush trees on the Pear stock, and though smaller as regards size than wall trees they were of excellent flavour. I have seen fruit from large trees in a wet clay soil crack badly, and this shows it requires a well-drained soil; doubtless such is the soil where this beautiful Pear originated at the village of Tongre Notre Dame, in Belgium. It was raised by M. Durondeau, hence its name in this country. The late Mr. Blackmore, the novelist, a great lover of Pears, who never hesitated to give a Pear a bad character when it failed with him, says of Durondeau that "it is a great bearer, very pretty, but always acid," and doubtless this is correct, as the fruit from some soils has a harsh taste, whilst in others the flesh is sweet, melting and tender. There can be no doubt whatever of its value on account of its cropping and size, and its free growth in any form will always make it a favourite.

G. WYTHES.

APPLE NANCY JACKSON.

APPLES are an important factor in the welfare of the people of this country. Almost everybody likes them in one form or another, and when eaten raw they are known to be beneficial to health. We cannot complain of any deficiency in the number or quality either of the dessert or culinary varieties of Apples, though their cropping abilities vary considerably. In a private garden many sorts can be grown that in a market garden would have to be discarded, as the market grower requires quantity, quality, and size. Whilst not pretending to give a full list of the best varieties, the following

may be relied upon as worthy of a place in any garden. For dessert: Ribston Pippin, Cox's Orange Pippin, Red Juneating, Mr. Gladstone, Adam's Pearmain, Scarlet Pearmain, Worcester Pearmain, Golden Russet, Yellow Ingestre, and Warner Pippin. For cooking: Alfriston, Bismarck, Blenheim Orange, Keswick Codlin, Old and Improved Cockpits, Ecklinville Seedling, Lady Henniker, Lord Derby, Lord Grosvenor, Lord Sutfield, Mère de Ménage, Peasgood's Nonsuch, Chaplin Pippin, Cox's Pomona, Pott's Seedling, Wellington or Damelow's Seedling, and last, but not least, Nancy Jackson. This last variety, although very little known in the south of England, holds a high reputation with the market gardeners in some parts of Yorkshire. It was originally introduced into the York district by Mr. Danley, the York

and Ainsty huntsman of a past generation, who discovered it at Yarm. It has now taken a firm hold in this neighbourhood, and one hears of many young trees being planted every year. In my garden there are about one hundred trees of Nancy Jackson which appear upwards of thirty years of age. They bear a fair crop of fruit every year, and I have gathered three and four large Apples from the end of a branch no thicker than the tip of one's little finger. It has all the points that a good Apple should have, being large, viewly, late, and of excellent quality. Mid-season Apples suffer from the fact that their time of sale corresponds with that of the fallen fruit, which in recent years has been regular and plentiful. Fallen Apples can be bought for 1s. per bushel, whereas the gathered fruit should make 6s. the bushel. With a late variety like Nancy Jackson the fallen fruit makes no difference in the price, as they may be stored the day they are gathered and left in the fruit room for five or six months without being attended to, and then be sold for 8s. to 12s. per bushel. During a storm, whilst other sorts are shedding their fruit in every direction, this variety holds fast to the tree, and even the fallen fruit will keep for months if their skins are not broken. I am told that very few nurserymen catalogue this Apple, but its merits demand that it should be more widely known. I learn that the first shipment of Apples from Tasmania sailed on the 17th of this month. These Apples will make 20s. per bushel, and surely this is a reason why the cultivation of the best Apples, and especially late ones, should be encouraged in this country. GEO. HOLMES.

Accomb, York.

GARDEN CARNATIONS.

THE advent of spring, when it is accompanied by soft breezes and sunny days, irresistibly turns our thoughts to open-air gardening, with the result that we not infrequently suffer loss through over-hurry. Caution in early spring is therefore a great virtue, and we exercise it to its fullest extent with Carnations, which, though hardy when established, are apt to suffer from hard as well as from wet weather when lately planted. In the case of open soils, planting can be proceeded with long before heavy soils are in fit condition, and it is in those of the former class only that this operation should be carried out at the earliest moment the ground is fit. Some dry sandy compost, or even sand alone, mixed with the natural soil, and packed about the roots of Carnations, is of much value in promoting a more rapid root-action, and when the plants are strong it well repays the trouble to attach each growth to a short stick, which steadies it during high winds. Carnations succeed better in firm than in loose soil, and on this account the ground should be treated in the same way as is usual for the Onion crop, by trampling it with the foot or compressing it by means of a roller. Should, however, it be inexpedient to firm it previous to planting, as soon as the ground is sufficiently dry to permit of the operation it should certainly be effected—in these circumstances, of course, by foot trampling. I would advise extreme caution in manuring ground for Carnations, which when ordinarily fertile requires no manure, the evil effects of manuring appearing in gouty stems, and in autumn in the greater susceptibility of the foliage to "spot."

Manurial aid can at any time it is thought to be required be given in the form of surface dressings, sweepings of pigeon coots being suitable, and also fresh soot, than which no material yields better results provided it is applied in sufficient quantity. Soot is also valuable dusted on the foliage of Carnations when wet as a protection against birds, which of late years have become a pest. It is, indeed, advisable

where small birds abound to apply soot to the foliage directly planting is completed, because once they get a taste of the leaves they are not easily stopped from further raiding. Some seasons the weather in spring is so unpropitious, that planting is delayed beyond the period one can expect the plants to do well. Last year was of this kind. The best course to pursue when this happens is to pot on the plants into 5-inch pots, keeping them as quiet as may be, and not attempting to place them in their outdoor quarters until every suspicion that harm may follow has disappeared. I was obliged to plant several clumps with plants treated as above early last summer, and I was not dissatisfied with the result.

No doubt the best method of outdoor culture is to plant them into permanent positions in autumn. Stronger and more free-flowering plants are obtained and there is less labour. These also require attention at the earliest opportunity, when surface weeds should be removed, and the ground slightly stirred and then dusted with a ½-inch layer of soot. Previous to application, however, the plants should be examined carefully and every bit of withered or spotted foliage cut off. If through too late planting any have slightly protruded above the surface, press them gently down to the general level.

Perhaps less thought is given to the selection of varieties best suited to open-air culture than the case demands. There is too much running after novelty without considering whether new varieties possess any greater or equal merit to those we already have. The points chiefly to be considered in an efficiently equipped Carnation are, I think, a vigorous constitution, profusion of flowering, an upright habit of growth, and the possession of decided colour in the flowers. For these reasons, I would choose such old varieties as Raby and Vivid in preference to many novelties. The drooping habit that affects so many sorts I would indeed consider sufficient cause for exclusion from the garden, where much tying is unmitigated by any corresponding benefit. It is, too, perhaps worthy of note that the prevailing methods of arrangement opens to Carnations as decorative subjects a wider field than they formerly held. A dozen, or a score, or a couple of hundred plants of a variety, as we choose, properly selected and judiciously grouped, add a charm to any garden. But against this we have to place the almost certainty of failure following the employment of varieties deficient in any of the points insisted on above.

Some varieties, otherwise valuable, are apt to decline in vigour after a few years' cultivation, and this fact shows us the need of occasionally importing new blood, Carnations undoubtedly being adversely affected by some soils, and being very responsive to a change. Yellow and apricot-coloured sorts are affected to the greatest extent, but the benefit of a systematic introduction of plants from another soil is not confined to these. R. PAGE.

ORCHIDS.

ODONTOGLOSSUM CRISPUM HARRYANUM

ONE of the finest additions that have been made to the *Odontoglossums* for some years, and the fact that it has been artificially raised between the species indicated by the name should dispose of the idea which has grown amongst hybridists that *Odontoglossums* cannot be raised from seed. There must be an

end to the great importations which are annually being introduced. I was struck recently by the similar characteristics of two plants exhibited at the Drill Hall under the name of *O. crispum Harryanum* to those plants which had been previously certificated as being the inverse cross of each other. In the one the segments were extremely long and narrow, very light in colour, and the spots sparingly and evenly distributed, resembling the plant originally certificated at the Temple show a few years ago. In the other (a flower of which I have before me) the segments are much shorter and the flower altogether more compact. The sepals are each about 1½ inches long, pale creamy yellow, broadly barred across with brown spots. The petals are not quite so long as the sepals, deep purple, beautifully margined, marbled and tipped with creamy white, the basal half yellow on the disc, where there is a tuft of prominent bristles. From the disc to the outer margins there is a thick covering of purple of the same shade of colour as seen in the lip of *O. Harryanum*, marbled and mottled with white, the apical half white and much crisped on the margin. This variety resembles greatly the plant exhibited as the reverse cross, which received a second certificate. The raiser, when offering the plants for sale, did not see fit to distinguish the crosses. The question may, therefore, be reasonably asked, Did the two varieties originate from one pod of seed? H. J. C.

CYPRIPEDIUM LORD ROBERTS.

(*C. CHARLESWORTHII* × *C. CREON*.)

LIKE *C. Spicerianum*, the use of *C. Charlesworthii* as a parent in the production of hybrids has been practically a failure. It is, therefore, pleasing to note one exception. *C. Lord Roberts* was raised by Messrs. Charlesworth and Co., Heaton, Bradford, Yorkshire, and was exhibited by this firm on December 19 last at the meeting of the Royal Horticultural Society, being awarded a first-class certificate. The dorsal sepal is 2½ inches in diameter, white at the top, slightly tinted with rose. It gradually becomes more intensely suffused towards the base. There are numerous prominent rich purple veins spreading from the base towards the outer margins. The petals are rather more than 2 inches long and highly polished: the lower half is purple mottled with green, the upper half being suffused with a darker shade of colour, showing the influence of *C. villosum*, introduced through *C. Harrisianum* being found in both parents of *C. Creon*. The lip is deep brown and highly polished, the disc on the column being pale rose veined with green. As stated above, the flowering of *C. Charlesworthii* hybrids has been disappointing, especially when crossed with species of the Eastern section with tessellated foliage.

JOTTINGS FROM CEYLON.

FOR the variety and beauty of its products, combined with the salubrity of its climate, probably Ceylon, compared with any other country of the same size, stands unrivalled. During a recent and somewhat prolonged tour, embracing many countries in tropical regions, and with experience gathered from wide wanderings hither and thither through this wicked, but beautiful world of ours, the writer certainly is very decidedly of the above opinion. The wealth and profusion indeed of the growths of this glorious earthly island paradise are at the first blush somewhat bewildering, for as you skim along in your rickshaw, ride among the outskirts, and through the cinnamon gardens of steamy Colombo, there will speedily be introduced to your enchanted gaze numerous varieties of the Palm, Mango, Bread-fruit tree, Banana and Mangosteen, besides Pine-apples, also Prickly Pears, and countless other growths. Gliding along half-embowered lanes fringed on either side may be with sentinel Cocoa-nut trees, you revel in the grateful shade after the glaring sunshine endured in Colombo itself,

marvelling the while at the extraordinary endurance of your coolie, running mile after mile in such great heat, with no apparent exertion or effect other than a somewhat profuse perspiration on his shiny skin. Returning for a breeze by the open sea, you are, nevertheless, glad that to-morrow will find you out of this vapour-bath, high up in Kandy, than which, though I have sojourned in manifold cities and countries, I know no more peaceful or beautiful spot—an inner oasis, as it were, even in a country so marvellous throughout in its perfections, that it may perhaps claim for itself the title of the very pearl of creation itself.

Up in Kandy then, and higher if you will, to wilder and grander Nuwera Ellia, you will find it wise to make a prolonged stay. The former, however, struck me as being the more fascinating, its beautiful lake, fringed and mirrored with Palms, being not the least of its multitudinous enchanting features. Saunter out in the comparative cool of the mystic scented evening, and in a few moments you will find yourself in a rickshaw being wafted you care not where, so enwrap are you in the romantic spell of a delicious dreamland. Your "boy" may be taking you miles in the country uphill and down dale, with fireflies dancing all around and fragrant perfumes all about, beneath canopies of exquisite foliage, with glints of the departing gloaming now and again peeping through the trees; or you may be skimming around the fairy lake and flitting past the little Buddhist temple without a sound to break the wondrous repose and gladness in which your soul is revelling. No other place, methinks, exceeds in subtle charm and perfect rest this beautiful spot at evening. For a study of India's growths and tropical productions in general you will find yourself making repeated trips out to the far-famed Perideniyeh Gardens, lying as they do but a few miles outside Kandy. I must confess to being less enthusiastic as to the Palms than a charming American lady, to whom it was my privilege to act as escort on several occasions, and I fear somewhat lost caste in her eyes when more than once I produced my butterfly net and a small boy and entered heart and soul into catching the beautiful and vivid specimens with which these gardens abound. But I think even my fair friend was interested in the very curious flying foxes of which there is a kind of rookery in some tall Eucalyptus trees. Perhaps the most attractive of the Palms, at any rate from an eccentric point of view, was the Sealing-wax Palm.

The road (a broad bowery lane would better describe it) from Perideniyeh is in itself a perfect study of tropical productions. Banana, Durian, Mango, Bread-tree fruit, Eucalyptus, Cocoa-nut, Date and other Palms, Jack-fruit, and a host of others abound in the greatest profusion, while just beyond Perideniyeh a comprehensive idea of the growth and manufacture of tea may be readily and instructively obtained. Some little distance from Kandy may be seen the vast estates of Messrs. Lipton, situate in mountain and valley surroundings of very great beauty. Of the tea and coffee grounds of Ceylon, however, I saw but little, though in my case, having seen the industry on the lowlands beneath the Himalayas between Calcutta and Darjeeling, and the extensive plantations in the Nilgherry Hills around Coonoor, in Southern India, I was well content to rest on my laurels in that respect. But for contemplation generally in Nature and her varied growths, combined with perfect peace and (for the tropics) a comparatively cool climate, commend me to the elevated positions of Ceylon in general, and of Kandy in particular. VIATOR.

NORFOLK ISLAND PINE.

(*ARAUCARIA EXCELSA*.)

How often one hears the remark, "I wish the Norfolk Island Pine was hardy in England." Unfortunately, it is not so; but one can obtain a good idea of it from the specimens in the temperate house in Kew Gardens. The specimen figured was planted in the garden of Mr. Henry Mathew Arderne at Capetown by his late father about fifty-six years ago. The plant at that time was 6 inches high, and was brought to Capetown by an Australian captain. Mr. Arderne paid £5 for the young tree. The specimen is now 130 feet high, and is believed to be the tallest in the world outside Norfolk Island. This fine tree was known in England half a century before Mr. Arderne's tree was planted. It is stated in the second edition of "The Hortus Kewensis," vol. v., p. 412, that it was introduced in 1793 by the Right Hon. Sir Joseph Banks, Bart., K.B. The only other *Araucaria* mentioned is *A. imbricata*, the Chili Pine; it was introduced three years later by Mr. Archibald Menzies.

J. D.

COLD WEATHER NOTES.

THE SNOW PAUSE.

LIKE the people in "The Pilgrim's Progress," we have arrived at a place called "Stop!" Everything is at a standstill. The new paths that we were making through the copse; the ground that was being prepared for grass sowing; the flower beds that had still to be cut to the right shape; the sods that were coming from a distant common where they were to be had discreetly; the whole bustle of the garden is brought suddenly to a state of arrest. Into the middle of our fussy little rhythm Nature has dropped her own big imperious full-stop. Against that full-stop there is no appeal. In vain we protest to her that we are really and truly in a desperate hurry. That unless these particular flower beds are made, unless especially yonder piece of ground is got ready for grass sowing, March will be upon us swiftly, close at its heels April, that the spring is coming on, and that we *must* positively get our work done. To this remonstrance of ours Nature merely opens her eyes with a mildly sarcastic air, and replies, "Must you!" One feels oneself to be precisely in the position of the old woman of the nursery tale, who *had* to get her pig over the stile in order to give her old man his supper. In that case, if I remember rightly, she did, after many repulses, find a complacent beast who undertook the task. The right spring was touched; the spell was broken, and the whole state of deadlock dissolved at once. How in such a case as this to obtain so desirable a dissolution we have yet to learn. We know of no spring to touch, no bird, beast, or element that can be appealed to with the slightest hope of success. The sky, iron-grey, with vicious inky streaks across it, does not seem promising; neither does the wind, which keeps to its beloved north-east. The earth is invisible, and is, therefore, for the moment out of reckoning; while as for the birds and beasts, they are much more disposed to turn to us to help them than to make any friendly propositions the other way.

It may be a piece of mere vanity upon my part, but it always seems to me that the smaller birds recognise their heavy, wingless, two-legged kinsfolk with less difficulty during this sort of weather than at any other time of the year. The fact that we bribe them to such recognition by vulgar doles of breadcrumbs

may have something to say to it, but I fancy that I read a distinctly less-alloof, less-smubbling expression in their eyes. They glance up at us with an air of comparative condescension. They perceive we share their own helplessness; that we are not after all so very different from themselves, only bigger and stupider. For instance, I have been publicly and painfully snubbed this whole winter by the tomtits. Under the eye and in the knowledge of the entire garden I set up a large post, hung over with cocoa-nuts, for their convenience. Some of the cocoa-nuts were sawn into slices, others, more artfully, into

heard that there were sparrows who were less particular, but it had never been *their* custom! I felt—as anyone naturally would feel under the circumstances. To-day for the first time, thanks to the friendly connivance of the snow, this fastidiousness has broken down. With elation I perceived that my disdainful blue friends are not only pecking at, but actually sitting and swinging in the long-despised brown rings. I hope that I am bearing my triumph meekly, and am helped towards doing so by reminding myself of the well-known fact that in times of stress and famine social dis-

THE NORFOLK ISLAND PINE (*ARAUCARIA EXCELSA*), 130 FEET HIGH, IN THE GARDENS OF MR. H. M. ARDERNE, CAPETOWN.

rings, and I pleased myself by believing that they would sit and swing in them as they pecked an unfamiliar, but not unpalatable meal. Will it be believed that not one single tomtit has ever deigned to touch those cocoa-nuts! They hopped to and fro on the boughs almost within peck of them, yet never so much as ascertained whether they were eatable or not. They preferred, in fact, not to do so. In *their* family, they practically sent me word, they never eat victuals that had not been selected by themselves. Other people might do so, and they had

tinctions are apt to break down. I shall have to wait accordingly till the weather relaxes to see whether this amiability is anything more than a sort of truce, born of the hour of trouble, and not intended to last beyond it.

How odd, if one comes to think of it, this whole thickly encrusted, and apparently solid, white setting is, and not at all the less odd for being so perfectly familiar. Looking round me to-day, I begin to wonder why I should have taken the trouble to go and listen to Captain Nansen, or to have followed with such profound

interest the record of his indescribably uncomfortable journeyings. Had I even the slightest desire to share in his sensations, to do as he did, or to sleep as he slept, why I could do so this evening! I will not pretend that I have the slightest intention of doing anything of the kind, and I merely mention it as a proof of how easily experiences which illustrious travellers court at vast cost and peril to themselves come wandering of their own accord quite readily to the very humblest doors. It was the tropical or sub-tropical regions of the globe that not very long ago were good enough to send us specimens of their weather, as enterprising tradespeople enclose samples of their goods in envelopes. There were days last summer—to be accurate, I believe, there were sixty-three of them—when it was by no means necessary to go to the Sahara or the South-eastern Soudan in order to ascertain what a state of almost mendicant drought could be like. For the present I feel that these two samples will suffice me. I cannot, unfortunately, return them, since I do not know their sender's address, but I feel under no obligation to charter either camels or whale-boats in order to go and make their acquaintance upon a larger scale.

As for the mere ferocity and killing powers of Nature even in such comparatively sheltered scenes as these, we are not without a taste of her capacity in that respect. Apart from the wild creatures, which have to look out for themselves, she exacts in weather like this a pretty stiff list of victims from the old, the weakly, and the very young.

My Chow dog insisted upon my taking a late run through the snow this afternoon, and, as we stood for a moment near the stile, there came up a melancholy little chorus of lamentable bleatings from some sheep-fold in the valley below us. I peered over into the white darkness, but could see nothing. My Chow licked his lips, and I earnestly trust he was not thinking of mutton. It may be mere weakness or stupidity, but I have always felt glad that in my various commings with the good green earth I have stopped short at the garden, the wood, the bog, the hillside, the sea-shore, but never once stepped into the paddock or the farmyard. Reading Rider Haggard's admirably written "Farmer's Year," as I have been lately doing, the one drawback to my pleasure, and a very considerable drawback it was, was the eternal and detestable apparition of the butcher! Whenever the small lambs, that frisked so delicately, were beginning to grow pleasantly plump; whenever those Irish bullocks, whose vicissitudes one followed so breathlessly, were pronounced to be certainly not improving as fast as they ought; even when the poor old milk cow, who had given so much good milk and had brought so many calves into the world, had begun to flag—always there was that abominable apparition in a smeared apron waiting for them close by, or peering in at us in a sinister fashion from round a corner. No, whatever other functionaries or local potentates I might be willing to share my pursuits with, assuredly I could never, never consent to share them with Mr. Bones! The objection may be puerile or merely sentimental, but then so are most of our likings and dislikings merely sentiment. Now as for these green clients of ours, it is quite true that they do die pretty frequently upon our hands, and the fact, no doubt, is a very distressing one, the more so as in nine cases out of ten we are quite aware that it is entirely due to our own fault. Still, we are able, as a rule, to take their demise with a remarkable share of fortitude and resignation; there are at least in their case no heartrending

squeals or groans, either heard or unheard. They go to their own place in peace, wafted as it were by slow music towards the gentlest of dissolutions. As for us, if we are their murderers, well, we manage to hold up our heads and take particular care never to allude remotely to the subject. On the contrary, we put on an air of extra cheerfulness and alacrity, and make haste to plant something else!

EMILY LAWLESS.

Hazlatch, Gomshall, Surrey.

ORIGIN OF SOME HYBRID GARDEN FLOWERS.

PELARGONIUM. The home of the Pelargonium is the Cape of Good Hope. Bentham and Hooker record 170 species, of which only two or three come from Australia or New Zealand. In 1855 Pritzl ("Index Iconum") enumerated more than 250 species and cultivated forms which had been figured at that date. Some of the earliest illustrations of species introduced into Europe appear to be about half-a-dozen from South Africa in a work of Rivinus in 1690, of which he calls the largest flowering *Geranium maximum*, and another species *triste*, which (if the same) was introduced into England in 1632. Of species which play an important part in modern floriculture the first to be imported were *P. inquinans*, in 1714, and *P. zonale*, in 1710. These are the parents of our "scarlets" and "zonals." The Ivy-leaved *P. peltatum* arrived in 1701. Other species were imported sparingly during the early part of the 18th century, but a large number came after 1770. In 1794 *P. grandiflorum* was introduced, and this species is the basis of many of our existing large-flowered or fancy Pelargoniums. Numerous hybrids and subsequent crosses have been raised, but those first formed early in this century were insignificant and probably are now lost to cultivation.

With regard to the form of the flower, the original shape is mostly very irregular, the posterior petals being often much the larger, while the stamens are declinate, the sub-genus *Hoarea* having lost the anterior petal. This structure is almost an invariable rule, that when the androecium supports the weight of the insect-visitor the petals below them are lost or atrophied, or at least not specially developed; just as in the Horse Chestnut, the stimulus, due to the weight of the insect, &c., being now thrown on to the stamens, only the posterior petals behind the nectary are presumably stimulated to extra growth.

This theory also accounts for mimetic resemblances in flowers, in that similar insects visiting different flowers, these latter respond to them, and so give rise to forms having a strong external resemblance to one another, but with no real affinity. Thus *P.* (*Hoarea*) *corydalliflorum*, like *Corydalis* itself, is not unlike a Vetch. Similarly we find genera with declinate stamens both in Labiate, as *Colens* and *Plectranthus*, and in Scrophulariaceae, as *Collinsia*, &c., which thus assume a pseudo-papilionaceous form.

PECUNIA. This genus contains about fifty species, chiefly natives of Mexico and South America, a few being found in New Zealand, such as *P. exorticata*. Like *Calceolaria*, it thus points to a former geographical extension from South America to New Zealand. The first species that appears to have been introduced was *P. coccinea*, probably from Brazil. The date is 1788, but as *P. magellanica* (also

called *macrostema*) arrived soon afterwards, it usurped the specific name of *coccinea*, and is now generally known as such. The true *P. coccinea*, supposed to be lost to cultivation, was discovered in the Botanic Gardens, Oxford, and still cultivated in Guernsey in 1832. Loddiges had figured it in 1825, and Sir J. D. Hooker re-figured it in 1868 in *Botanical Magazine*, t. 5740, showing that it was different in several particulars from the common or so-called *P. coccinea* of gardens. As this species is a native of the extreme south of Chili, it is hardy in the warmer parts of Great Britain, forming hedges and even trees in Cornwall, Jersey, &c. Several varieties of this species were imported about 1825, as *discolor*, *conica*, and *gracilis*, while *recurvata*, probably a hybrid, appeared at Glasnevin, Dublin, in 1835. The well-known *P. globosa* was first shown by Mr. Dennis, of Chelsea, in 1832, but whence it arose is not known. It is believed to be a garden variety of *P. magellanica*. There is a hedge of it at Lee, near Ilfracombe. In 1837 came the handsome long-tubed *P. fulgens* from Brazil. This was followed by the large-flowering species, such as *P. spectabilis*, from the Andes, *P. corymbiflora*, from Peru, *P. splendens*, from Guatemala, &c. As all *Fuchsias* appear to cross with each other readily, an innumerable number of hybrids and subsequent crosses have been raised. *P. Standishii* (*Bot. Reg.*, 26, 2) is an interesting one, as being a hybrid between two such extremely different species as *P. fulgens* and *P. globosa*.

CALCEOLARIA. Like the *Fuchsia*, this genus finds its home in South America. According to Bentham and Hooker there are nearly 120 species on the Andes, from the Straits of Magellan to Colombia and Mexico, while two occur in New Zealand. The first to be imported were four species with yellow flowers in 1822. Of these, *C. corymbosa* was soon used for hybridising with the purple *C. arachnoidea*, which followed in 1827. In 1831 *C. crenatiflora* was introduced, having a yellow corolla spotted with crimson and a deeply crenated "slipper." This species, *C. integrifolia* and its varieties, *angustifolia* and *viscosissima*, imported in 1822, laid the foundation of the subsequent innumerable forms. The species are either herbaceous or somewhat shrubby, but they all intermix freely. More than one experimenter raised hybrids from the above-mentioned species. The results were that either yellow or purple became the ground colour, the other forming a large spot upon it, or else they combined, producing scarlets, &c. The additional aid afforded by *C. crenatiflora* furnished the variously spotted forms now in cultivation. The shape of the corolla first aimed at was circular, but of late years this has passed into a more ovoid type, while the size has increased enormously; so that by calculating the cubic capacity of one of Mr. Carter's Japanese and Victoria *Calceolarias* and comparing it with that of *C. corymbosa*, it contains just about twelve times the volume of the slipper of the original species.

PETUNIA. The three species which contributed to the formation of our present garden varieties were *P. violacea*, purple (1831), *P. nyctaginiflora*, white (1823), and *P. bicolor*. They all came from Brazil. The last species is the origin of hybrids of a tender nature and less easy to cross. It originated the dark-mouthed and streaked kinds, having been crossed with *P. nyctaginiflora*. It is remarkable that for many years no doubles could

* For further details on the application of this theory to the structure of flowers, the reader is referred to "The Origin of Floral Structures," caps. xi., xii.

† *Botanical Magazine*, iii., t. 97: Though called *P. coccinea*, it is really *P. magellanica*.

be raised, when they appeared simultaneously both on the Continent and in England.

AMARYLLIS. This name, now appropriated by the well-known and handsome hybrids, is a retention of an old one given to a plant called the Jacobea Lily (*Botanical Magazine*, 17). A. (*Sprekelia*) *formosissima*, named in honour of Dr. Sprekel, a native of Guatemala, and introduced into Spain before 1593. The name *Amaryllis* is now confined to *A. Belladonna* of the Cape. Those species which have entered into the composition of the modern florists' productions belong to *Hippeastrum*, so named from their fancied resemblance to the star of an equestrian knight.

valuable results of hybridisation is the tuberous *Begonia*. Four species have laid the foundation of the innumerable varieties now in cultivation. They are as follows: *B. Pearcei*, introduced in 1865 from Bolivia, has yellow flowers about an inch in diameter (*Botanical Magazine*, 5545); *B. Veitchii*, 1867, Peru (*Botanical Magazine*, 5663), has large flowers, rose-red, and about 2 inches in diameter; and *B. boliviensis*, 1864 (*Botanical Magazine*, 5657), from Bolivia, has an elongated form of flower, the petals being about 2 inches in length and acuminate. These three laid the foundation, then *B. Davisii*, with flowers of a brilliant orange-scarlet, from Peru, 1876,

to lose its beauty. Mr. Veitch has also raised a new series between *socotrana* and the above-described hybrids, valuable for their late blooming. GEORGE HENSLOW.

CROCUSES UNDER BEECHES.

THERE is no statement more frequently repeated respecting garden or woodland planting than that nothing will grow under Beech trees. Like many other sweeping assertions that are in the main erroneous, this one has a grain of truth. For if we wander among the chalk hills, where the great wild Beeches—perhaps the very grandest of our forest trees—stretch

CROCUSES UNDER A BEECH TREE AT SEVERN HOUSE, BEWDLEY.

The foundation of these hybrids was laid in *H. vittatum*—*Reginae*, introduced in 1769 and 1725, respectively. The latter was called the Mexican Lily. The result was called *H. Johnsoni*, raised in 1810. About 1867 the species *pardua* was introduced from Peru, and in 1869 Mr. Pearce brought forward *Leopoldi* (named after the King of the Belgians). From these new hybrids were raised, and, with the assistance of the species known as *Aekermanii* and *puleherrina*, there have appeared the vast array of hybrid varieties now familiar to all. *Sprekelia*, which has a remarkably irregular flower, has always proved very refractory, though it has been crossed with *longifolia*.

BEGONIA.—The latest and one of the most

was used with hybrids between *B. Veitchii* and *B. boliviensis*, and some beautiful results followed. The flower being unisexual, it was not long before the staminate flowers became double, and so added considerably to the value of the hybrid progeny.

In 1879 Professor Balfour introduced *B. socotrana* from the island of Socotra. This has rose-coloured flowers rather more than an inch in diameter and peltate leaves. Crossed with *B. Dregelii*, a white-flowered species introduced in 1839 from the Cape, it has produced a valuable acquisition in the more well-known *Gloire de Lorraine*, a very floriferous plant, and as it is at first entirely male, it lasts long; female flowers are produced later, as it begins

their great arms wide and high, we find beneath them no forest sward, or Bramble tangle, or brake of other bushy growth; nothing but the carpet of dry rotting leaves, this leafy carpet remaining undecayed for a longer time than that of the shedding of almost any other forest tree. But it is to be remembered that gardening is the introduction of plants, for the advantage of their utility or for enjoyment of the gladness of their beauty into places where they would not otherwise occur, and we gardeners have of late years found out that even the dry hard soil under Beech trees may be made to bring forth abundant flower-beauty.

How well Crocuses thrive even under Beech trees is shown in our illustration.

THE ROSE GARDEN.

PAPA GONTIER AS AN INDOOR ROSE.

IN addition to the beautiful pink Roses, such as Caroline Testout, La France and Mrs. W. J. Grant, which will soon be seen in every florist's shop, that fine variety Papa Gontier will undoubtedly be met with in large numbers. Growers for market have not as yet found a better high-coloured Tea Rose for mid-winter cutting than the above. Its buds are perfectly handsome and of a very intense rosy crimson shade of colour. Many who grow this Rose outdoors are surprised at its behaviour under glass, for in summer there is nothing much in the flower. When, however, the growths are developed rather slowly under glass, the petals stiffen and increase in size until the flower assumes a totally different character to what one is accustomed to find outdoors. Anyone desiring a high-coloured erect-growing Rose that is easy to grow and prolific in blossom could not do better than plant out a quantity of this variety. Lord Brougham instances bushes of it at Cannes that have attained the dimensions of some 25 feet in height by 7 feet in diameter. What a picture such a shrub would be growing in the centre of a Rose house! I often wish I had the opportunity of affording plenty of space for such Roses under glass, where they could be planted out and allowed to attain the magnitude alluded to above. We cannot expect such specimens outdoors in our fickle climate, but there is nothing to prevent this consummation in a nice modern-built Rose house, where the plants are enabled to receive a far greater degree of sunlight than in the old-fashioned thick-raftered houses.

PILLOWELL.

NABONNAND'S ROSES.

Of the many continental raisers of Roses, few, if any, can claim so large a number of sterling novelties as MM. P. and C. Nabonnand. To name only a few of the best out of the 157 upon my list will give a good idea of the great service this firm has rendered to rosarians.

I was induced to look up the varieties from Golf Juan through noticing how many of our very best decorative Roses have come from there. It is a singular fact that several really grand Roses have been all but missed by our principal Rose growers here. For example, we have Georges Nabonnand, so prominently mentioned by THE GARDEN a few years back, and which very few were acquainted with. During the present winter we have another Rose on the market that very few British growers stock. This is the deep flesh-rose Paul Nabonnand, certainly one of the very best for winter culture. But to give a little description of what are, perhaps, the twelve best varieties from this firm.

Franziska Kruger (often spelt Françoise Kruger) appeared in 1880. For hardiness and general free-flowering qualities, also for pot work, it is indeed hard to beat this beautiful coppery-salmon Rose, and a more constant variety of its colour does not exist. Papa Gontier was sent out in 1883, and is a truly grand button-hole Rose, especially late in the autumn or when forced. The petals are large, buds extra long and firm, and the colour a deep red. A very free grower and almost always in bloom. The satin white sport from this was introduced in 1894 and is named Fiametta Nabonnand. It is one of our very best light-coloured Roses for any purpose except among what are known as "exhibition Teas." Princesse Vera, Paul Nabonnand (already mentioned), Comtesse de Pansse, and Cannes la Coquette all appeared in 1878. Agathe Nabonnand (1886), Isabella Nabonnand (1874), Marie d'Orléans (1884), Duchesse de Vallombrosa (1879), Bardou Job (1887), Reine Olga de Wurtemberg (1881), and L'Idéal (1887) will give the reader an idea of MM. Nabonnand's success in raising new Roses of merit.

RIDGEWOOD.

THE TEMPLE OF CONCORD AT GIRGENTI.

Al Tempio (To the Temple).

We ask the goat-herd whither leads
The path beneath the silvery leaves
Of Almond woods and wheat-green meads,
"Al Tempio."

With columns slim, enclosed in blue,
Concordia stands against the sky
"Signora, may we come with you,"
A host of eager children cry.

Al Tempio!

They sing and play—they show the way
Picking berries—eating cherries;
In and out amongst the corn
We follow them throughout the morn

Al Tempio.

The mountain range *celesti* lies;
Azzurro sleeps the waveless sea;
Turchino are the cloudless skies,
And gentians blue encircle me.

Al Tempio.

We see Girgenti far away,

On high, mysteriously defined;
Till fall of day we dreaming stay.

With gold in front and blue behind,

Al Tempio.

M. C. D.

[The Temple of Concord at Girgenti, in Sicily, is one of the best-preserved and most remarkable examples of ancient Greek architecture.

The Italian words *celesti*, *azzurro*, and *turchino* all express some degree of brilliant and beautiful blue colouring. Ed.]

While winter's snow is still upon us and we have yet to face the freezing winds of March, it is good to turn our thoughts to those distant southern

beast lived and moved amid the throng of worshippers.

To-day it is roofless and silent, and still it stands, as it may yet stand through other hundreds of years, an undying monument of the earlier ages of a civilisation wherein the sister arts of architecture and sculpture attained to a height that has never since been reached.

And, thinking of how the sentiment of love and veneration for the flowers and the green-growing things that now make the happiness of our gardens was present in the minds of the Greeks of old, we remember how some plants and leaves became identified, as their special attributes, with certain of the gods and heroes of the ancient Greek mythology of Bacchus crowned with flowers, while his servitors bore the *thyrsus* of pine-cone mounted on a ribboned rod, and of the places dedicated to his worship that were hung with branches of Vine and Ivy. And of Hercules, wearing in ancient sculpture chaplets of many kinds; of Ivy or Poplar, of Pine, Bay or Olive, or of interwoven flower and ribbon; while we yet may see the altars where the living laid their offerings, sculptured round with flower-garlands, while the chiselled Ivy still decks the marble casket that held the ashes of the dead.

A VILLA GARDEN. II.

Be careful to avoid an excess of plants, whether trees or shrubs, which have silver, gold, copper, or other unusual foliage. Although they are excellent at due intervals for lightening and giving variety to a shrubbery, they can easily be overdone and produce a garish and unnatural effect. This is particularly the case with the Golden Elder, which, though it has a very fine appearance on a large place when

THE TEMPLE OF CONCORD AT GIRGENTI, SICILY.

shores, where even now there are days of hot sunshine and skies of cloudless blue: where, as on the South Sicilian coast the Almond trees are already in bloom, and century after century the ancient Grecian temple stands, its marble mass gold-lichened against the blue of sea and sky and distant shore.

And we think how, long ago, on the days of solemn festival, the massive building, whose archaic Doric would proclaim its antiquity even if history were silent, had its pillared porch thickly hung with green garlands, and how its flower-crowned, white-robed priests and wreath-decked sacrificial

seen from a distance, is gaudy and staring when you are close by it. I may mention here that all golden plants, as far as I know, except the Aucuba, require full sunlight to make them colour properly. Expense being often an object for those who are planting a small garden, it may be well to remember that money will go immensely further in deciduous than evergreen stuff. It would not be difficult to stock the whole of a moderate-sized garden with 150 varieties of different deciduous trees and shrubs, not spending more than 2s. 6d. on any single

plant, whereas fair specimens of fancy Yews, Cypresses, Junipers, and other larger conifers could not be obtained under 7s. 6d. or 10s. apiece. In giving a list of some trees and shrubs suited to a villa garden I shall not mention any expensive evergreens, but confine myself to some of the cheaper shrubs sufficient to warm up and furnish the garden in winter. One of the principal objects to aim at in any garden is to have a succession of flower all the year round, and this in a mild season can be obtained with a little pains from trees or shrubs,

flowering : Ash, silver variety and flowering ; Beech, Copper, cut-leaved, crested ; Snowy Mespilus, common and canadensis ; Spanish Chestnut, gold and silver varieties ; Nettle Tree (*Celtis australis* or *occidentalis*) ; Cherry, double-flowering, *semperflorens*, and *Padus* ; Judas Tree (*Cercis siliquastrum*) ; Hawthorn, double scarlet, pink, and white, *orientalis*, *crus-galli*, *præcox*, *tanacetifolia* ; Maiden-hair Tree (*Salisburia*) ; *Gleditschia triacanthos*, *Koelreuteria*, *Laburnum Alleghingerii*, *Parkesii*, and *Scotch* ; *Liquidambar*, *Tulip Tree*, *Mul-*

never more than a matter of two or three pence except in the case of quite recent introductions. I calculate that it will be possible for anyone that is going to plant a garden to get one hundred of the above deciduous shrubs, twenty-five deciduous trees, and seventy-five evergreen shrubs for about fifteen guineas ; with the expenditure of another £5 it would be possible to obtain a sufficient assortment of creepers, also some hardy Roses and a good assortment of herbaceous plants, and in this way a collection might be made larger and more interesting than is usually seen in gardens of much greater size and pretension than the one I have tried to describe.

VICARY GIBBS.

Aldeham House, Elstree, Herts.

CLEMATISES AS WALL CLIMBERS.

THE merits of this climber demand many more to be planted than is the case at present. For walls or stems of trees these climbers are unsurpassed.

Clematises are more accommodating as to situation than many suppose. The variety *Jackmanii*, so well known for its mass of violet-purple blossoms, will succeed well on a northern aspect ; coming into flower there later than it does on a south wall, the period of flowering is prolonged. This variety is well worth a place in the centre of a flower bed, where it will annually give an immense crop of flower if it is pruned to within an eye or two of the ground every year in February and its roots freely supplied with manure at the same time. The culture of the Clematis as a wall climber is not at all difficult.

Soil that is heavy and retentive of moisture is unsuitable for Clematises, because it delays growth in the spring too long. A suitable compost would be turfy loam three parts, one part peat or leaf-mould, and one-sixth part of half-decayed horse manure with a sprinkle of road grit, sand, or wood ashes to keep the whole porous. The middle of March is a good time to plant Clematises ; even a month later will do, as the plants are always raised in pots, and they can be turned out of the pots without injury to the roots. After planting, should the weather be hot and dry for a time, mulch the surface 2 feet round with manure or leaves to prevent evaporation of the moisture. Mulching ensures a cool, moist rooting medium. When the plants are growing freely, liquid manure copiously given to the roots will promote vigorous leafage, which means a corresponding return in flower.

Pruning Clematises is perhaps the only point about their cultivation that requires special treatment. The sections require separate treatment.

As previously noted, that popular variety, *Jackmanii*, requires close annual pruning, as the blossoms are produced upon the current year's shoots. The white form of *Jackmanii* requires then the same treatment, and so do the following varieties : *Star of India*, reddish violet-purple, with red bars ; *Rubella*, velvety claret ; *Lilacina floribunda*, pale grey-lilac ; *Tunbridgensis*, bluish-purple ; and *Flammula*, small white blossoms.

Varieties of the *lanuginosa* section produce their blooms from the previous season's growth, therefore require but little pruning. This section includes *Alba magna*, pure white, purplish-brown anthers ; *Duchess of Teck*, pure white, delicate mauve bar when first opening ; *Lady Caroline Nevill*, bluish, mauve bars ; *Grand Duchess*, white, flushed rose ; *Henry*, creamy white ; *Duchess of Albany*, bright pink, deeper down the centre, softening to lilac-pink round the margin of the petals ; *Mrs. Hope*, deep lavender ; *Mme. van Houtte*, white ; *Louis van Houtte*, deep violet-purple, with darker veins ; *Albert Victor*, deep lavender.

The *florida* and *patens* section should be left untouched. Amongst these are *Duchess of Edinburgh*, double white, tree, vigorous, and fragrant ; *John Gould Veitch*, lavender-blue ; *Devoniensis*, bright azure-blue ; *Miss Bateman*, white, chocolate anthers ; *Sir Garnet Wolseley*, pale blue, plum-red bar ; *Mrs. Quilter*, pure white ; *Standishii*, lavender-blue ; and *Mrs. S. C. Baker*, pink.

B.

ALMOND TREES IN BLOSSOM IN SICILY.

As an illustration I would remind the reader that the various kinds of Aster and Hibiscus flower in late autumn, and the Hellebore and the Wych Hazel in the depth of winter, when in many gardens not a vestige of flower is to be seen. I now subjoin a list of plants suited to a villa garden which does not pretend to be exhaustive, and in which preference is shown to plants which are cheap, hardy, of moderate size, of striking appearance, and which flower freely. I cannot in the limits of this article go into details, and the reader, if unimformed, must refer to a nurseryman to see if any one of those here given be delicate or intolerant of smoke or particular soils.

EVERGREENS.

Arbutus Unedo, *Aucuba*, male, green, long-leaved, spotted ; *Berberis Darwinii*, dulcis, *stenophylla*, *Jamesonii*, *japonica* ; *Buddleia globosa*, *Box* in variety, *Laurel* (*caucasica*, *rotundifolia*), *Cistus* of sorts, *Cotoneaster* (*shrub*) *buxifolia*, *microphylla*, *Simonsi* ; *Pyracanthus*, standard or creeper ; *Daphne Laureola*, *Diplopappus*, *Euonymus* of sorts, *Garrya elliptica*, *Holly* of sorts, *Bay*, *Golden Privet*, *Olearia Haastii*, *Osmanthus*, *Phillyrea buxifolia*, *Ruscus Hypoglossus* and *racemosus*, *Skimmia japonica*, double-flowering *Spanish Gorse*, *Veronica Traversii*, *Laurustinus*, *Periwinkle*, green and variegated. All the above can be bought at about 1s. to 1s. 6d. each from any good nursery.

DECIDUOUS TREES.

Maple, *Colehiemum rubrum*, *laciniatum*, *Schwedlerii* ; *Sycamore*, silver var. and purple ; *Horse Chestnut*, yellow and red ; *Alder*, cut-leaved ; *Almond*, white and red ; *Peach*, double

berry, *Parrotia persica*, *Oriental Plane*, *Populus Bolleana*, *Siberian Crab*, red and yellow-berried ; *Pyrus Malus floribunda*, *P. M.*, *John Downie*, *White Beam*, *Mountain Ash*, *Scaveola Tree*, *Silver Birch*, *Scarlet Oak*, *Rose Acacia*, *Sophora japonica*, *Linne*, cut-leaved ; *Elm*, gold, purple, or silver. Good plants of the above can be bought for 2s. 6d. each.

DECIDUOUS SHRUBS.

Dwarf Almond, *Berberis*, common, *Thunbergii*, purple ; *Broussonetia papyrifera*, *Allspice* (*Calycanthus floridus*, *occidentalis*, *præcox*), *Caryopteris*, *Colutea arborescens* and *erecta*, *Dogwood* (*Cornus brachypoda*, *sanguinea*, *Spathii*) ; *Nut*, purple and cut-leaved ; *Cotoneaster affinis* and *Roylei*, *Pyrus japonica*, scarlet, white, or pink-flowered, and *Mauléii* ; *Broom*, white, *Andreana*, *præcox*, and *Spanish* ; *Daphne Mezereum* and white-flowered ; *Deutzias* of sorts ; *Dimorphanthus* ; *Spindle Tree* (or *Euonymus*) of sorts, *Forsythia suspensa* or *viridissima*, *Snowdrop Tree* (*Halesia tetra- ptera*), *Ribises* of sorts, *Hydrangea paniculata*, *St. John's Wort*, *Hypericum androsiumum*, *Moserianum*, *Kerria japonica* and *variegata*, *Lycesteria*, *Lilac* or *Syringa* of sorts, *Negundo* (white foliage), either as tree or shrub ; *Nuttallia*, *Philadelphus* of sorts, *Prunus triloba*, *P. Pissardi* (or purple Plum), *P. flore-pleno* (or double-flowering Sloe), *Rhus Cotinus*, *R. glabra*, *R. typhina* ; *Ribes* of sorts, *Shepherdia*, *Spiræas* of sorts, *Stephanandra*, *Symphoricarpos*, *Viburnum* of sorts, *Weigela* of sorts. All the above can be procured at from 1s. to 1s. 6d. each.

It is well to note that in their young state the difference in price between the more uncommon species and varieties and the most ordinary is

AN ARTIST'S NOTE-BOOK.

SPIRÆA PRUNIFOLIA
FLORE-PLENO.

THERE are few flowering shrubs more charming than the old double-flowered Spiræa, a spray of which is now figured. It is usually in bloom by the middle of April. The plant forms a dense thicket of slender arching stems graceful in habit and attaining some 5 feet to 6 feet in height. The leaves, as the name implies, resemble to a certain extent those of some species of Prunus—the Black-thorn (*P. spinosa*) for instance. The flowers appear very abundantly, three to six in a cluster, and are of the purest white. Each one is about half an inch across and almost perfectly double, resembling, in fact, a small Bachelor's Button. The shrub is an excellent one for the front of a shrubbery, or it may be planted in isolated groups or beds, in which case it is advisable to associate with it some dwarf evergreen, for, of course, it has but little foliage of its own when in flower. It may be propagated by cuttings, but I have found it is a quicker and more satisfactory plan to remove the young side-suckers from old plants in spring, pot them up, and give them a little heat for a few weeks. They soon set up active root-action, and can then be planted out. Whatever pruning is done should be mainly a thinning out of old and crowded stems.

I do not think the

Dr. Siebold's sale, is now in the possession of Louis van Houtte, florist, at Ghent." Plants, to be sent out the following April, are offered at one guinea each.

The single or wild type of *Spiræa prunifolia* is a plant of which but little is known. It is,

blue. It will interest growers of small alpine winter-flowering, hardy plants. W. W.

MERENDERA CAUCASICA.

A CHARMING little Crocus-like plant, which blooms in mid-winter with the earliest Snow-drops, and continues to push up its pale pink-mauve flowers in all kinds of weather. On a border at Kew it has been in flower throughout the trying weather experienced since Feb. 1, and when the snow disappeared the flowers were then as fresh as ever. It is also worth growing in pots, to be taken into a conservatory when in flower. The genus is closely related to *Colchicum* and *Bulbocodium*, but the flower segments are divided to the base, forming a cluster of slender filaments instead of a tube. Ten species are known, and they are natives of South Europe, North Africa, and the Orient. The flowers of all of them are either lilac or white, with bright green stamens. That here figured is probably the best for the garden. Although long known to collectors of choice bulbs, it is not found as often in gardens as its early-flowering habit and prettiness deserve. W. W.

TREES AND SHRUBS.

DECIDUOUS DAPHNES.

THE value of showy hardy flowering shrubs for decorative purposes is becoming recognised more every year, and those whose blossoms are produced during winter are specially welcome. With regard to the culture of the deciduous Daphnes, a cool, moist, rich soil and an open situation suit them admirably. *D. Mezereum* is a British plant, and, strange to say, a sadly neglected one in a cultivated state. Its clusters of sweet-scented rosy purple flowers are borne in great abundance along the entire length of the erect vigorous shoots in February and March. It is a lovely shrub for massing. There are several varieties of much merit, of which one named *grandiflora* or *autumnalis* should be cultivated extensively, as its blossoming period in mild seasons generally extends from autumn to early spring. The colour is a beautiful shade of rose-pink. Another variety, *alba* is noteworthy for its white flowers and yellow berries, but for general effect is less valuable than those named above.

LAURUS-TINUS.

So few are our good evergreens other than conifers, that those that we have are all the more precious. Though barely hardy in our colder midlands, the well-known *Laurus tinus* thrives in all but our worst climates. In mild winters its welcome flowering sprays are indeed precious, and if it is given a well-sheltered place, it will reward the planter's kindness with a bountiful mass of its pretty white

SPRAY OF SPIRÆA PRUNIFOLIA FLORE-PLENO.

(From a drawing by H. G. Moon.)

however, in cultivation, and has, I believe, flowered and fruited on the Continent. But it does not seem likely to ever rival the old double-flowered variety, which by long cultivation by the Japanese has been not only improved, but considerably altered. W. J. BEAN.

MUSCARI PRÆCOX.

THIS is one of the new garden plants that we owe to M. Siehe, of Mersina. It was introduced to Kew last year, and is now flowering in a sheltered border facing south. Strictly speaking, it is not a *Muscari*, but a *Hyacinthus*, and probably nothing more than a pigmy form of *H. azureus*, of which we know of several forms widely divergent from the type, the most striking, perhaps, being that named *H. azureus* var. *gigantens* by Mr. Baker, also one of M. Siehe's discoveries on Mount Muris, in Northern Cilicia, at an elevation of about 1000 feet. This form is the other extreme in size to that here figured, the latter being barely 3 inches high, whilst the former is almost a foot. The typical *H. azureus* was first introduced into gardens in 1856, but it was not generally known until about fifteen years ago. It grows about 6 inches high, and has a conical raceme $\frac{3}{4}$ inch wide of deep blue flowers. The plant here figured has a smaller raceme, and the colour of the flowers is light or Cambridge

value of this *Spiræa* for early forcing is generally known, or, at any rate, taken advantage of. A few batches of it have been forced this season for the decoration of the greenhouse at Kew. The slender wands studded with snow-white flowers are particularly graceful and effective, rising out of a mass of dwarf dark green plants.

Like many other valuable Japanese shrubs and plants, this was introduced to Europe by Dr. Siebold between fifty and sixty years ago. An advertisement in the *Gardeners' Chronicle* for February 20, 1847, states that "the stock of this magnificent Japanese novelty, bought at

A NEW GRAPE HYACINTH (MUSCARI PRÆCOX); FLOWERS TURQUOISE-BLUE.

(Drawn at Kew by H. G. Moon.)

bloom, while as yet there are but very few hardy flowers in the garden. It should be remembered that it is a shrub of Southern Europe, and therefore grateful for as warm and well-sheltered a place as it can have; indeed, it is by no means to be despised as a warm wall shrub, showing when so grown by its wealth of bloom and pretty blue berries how well it likes such good treatment, while its neat foliage and way of growth make it quite worthy of a good place.

It is a very strange thing that the other kind, the Black Laurustinus (*Viburnum hirtus*), should be so little known and grown. It is the hardier of the two, scarcely less good in flower, and more free and handsome as to its really ornamental bunch of berry, which has a remarkable degree of bright blue metallic lustre.

Viburnum lucidum, a native of the Atlas range, is a more beautiful shrub both in leaf and flower than either of the better-known ones, but, alas! is too tender for English gardens in general, though it would do well wherever Myrtle, Sweet Verbena, Fuchsia and Hydrangea stand the winter without protection. It is like our common Laurustinus enlarged and improved in both flower and leaf. It is usually the case that a plant that is an enlargement of a well-known type is made coarser by the increase of size, but though as a rough description *Viburnum lucidum* is a larger shrub of much the same appearance as the one with which we are so familiar, it has distinctly a more refined character in every way. The flowers are whiter and the ovary is somewhat looser; the foliage is also less stiff, of a livelier green, and bears a handsome polish, while the whole shrub is more elegant and free of outline.

TREES AND SHRUBS OF RECENT INTRODUCTION.

DURING the last decade our parks and gardens have been enriched by many ornamental trees and shrubs suitable for open-air culture in the British Isles. The following are a few of the most meritorious that have been put into commerce within the last year or so:

Amongst evergreens, *Ilex Golden King* makes a capital companion to the well-known *Hodgins' Holly*, a vigorous form with broad deep green leaves. In habit, vigour, and form of leaf *Golden King* bears a close resemblance to the last-named; in fact, it might almost be taken as a golden form of it. The leaves are irregularly, but clearly margined with deep yellow. The parents of the hybrid *Escallonia langleyensis* are very ornamental garden shrubs, *i.e.*, *E. philippiana*, a form from Valdivia with an abundance of small white flowers in July, and *E. macrantha sanguinea*, conspicuous for its lovely red flowers. The progeny takes after the first-named parent so far as habit of growth is concerned, but the delicately tinted rosy red blossoms remind one of those of *E. macrantha sanguinea*. It is very floriferous, free in growth, thoroughly hardy, and may be used with good effect in the mixed shrubbery or as a wall shrub, also for training up pergolas, &c. It is a gem amongst hardy evergreen free-flowering shrubs. *Picea (Abies) pungens glauca pendula* is a charming conifer of truly weeping habit. The long, pendulous branches fall close to the main stem, and are clothed with attractive greyish coloured leaves. It is of good growth and well adapted for planting as an isolated specimen on the fringe of the lawn. *Hamelis mollis*, the latest addition to the Witch Hazel family, should prove a fitting companion to the deservedly popular *H. arborea*, from which it differs in having larger leaves and flowers of a brighter hue. *Prunus (Cerasus) pseudo-Cerasus James H. Veitch*, shown for the first time at one of the Royal Horticultural Society's Drill Hall meetings last May, is a precious shrub, and unquestionably the best of the ornamental Cherries. In habit it is similar to *Waterer's Cherry*, but the flowers are larger, deeper in colour, and about a fortnight later in coming to perfection. The foliage, too, is very distinct, the colour being a pleasing shade of bronze-green, which affords additional variety. For

decorative planting it is sure to be in large demand. Another shrub or small tree belonging to the same family is *Prunus (Amygdalus) persica magnifica*, conspicuous for its gorgeous semi-double rosy carmine flowers. It is a splendid subject for forcing into bloom for the greenhouse and conservatory in early spring. *Humulus lupulus foliis aureis* is a fast-growing ornamental Hop. It is a lovely plant for clothing arbours, arches, and such like structures, and if exposed to full sunlight the colouring is very fine.

The *Deutzias* are very free-flowering shrubs with white or pale pink flowers. *D. corymbiflora*, introduced from China, is an acquisition to the group. It is of excellent growth, quite hardy, and bears corymbose panicles of pure white flowers in abundance.

BOOKS.

General Index to Miss Ormerod's Reports. In the "Report on Injurious Insects," published in May last year by Miss Ormerod, she mentioned that she intended that it should be the last of the series, and that the report on insects

MEIBOMIA CATASCIA: FLOWERS LIFE SIZE. (Drawn at Kew by H. G. Mann.)

noticed in 1899 should commence a new series. It was also stated that an index of the 22 reports already published was in course of preparation, and that it was being compiled by Mr. R. Newstead, the well-known curator of the Grosvenor Museum, Chester. This index has recently been published, and forms a very valuable and helpful addition to the series of reports. It consists of a preface by Miss Ormerod, a general index, plant index, animal index, and an index to unclassified hosts. In the preface the authoress gives a short history of the reports which at no little trouble and labour she has now drawn up for 22 years. She then gives with very short notes in each case a list of 17 different insect infestations that have been specially reported on. Referring to the continuance of the reports, she says, "For myself, so long as health sufficient for the work is granted me, and I am honoured by being asked to assist, it is only a pleasure to me to do my very best, and I hope to continue to publish yearly results, but with a little difference in plan, so that I may utilise short notes

General Index, by R. Newstead, F.E.S., to "Annual Reports of Observations of Injurious Insects, 1877-1898," by E. A. Ormerod, F.R.M.S. London: Simpkin & Marshall.

of useful means of prevention and remedy sent me in a separate section following the body of the report, and under a distinctive heading." She also mentions that she has arranged with Mr. Newstead to assist her when necessary. The value of these reports is very largely increased by this index, for it is now an easy matter to refer to any point in them, which before was a tedious operation. Every one who has this series of reports should make a point of procuring a copy. Indexing is a great art, and the modern system of giving in publications of this nature a general index and also special ones is very useful, provided it is well done, as it is for the most part in the instance before us. But there are some curiosities; for example, in the animal index the ox is given a separate heading, and is not included, as one would have supposed it would have been, under that of "cattle," so that anyone looking under "cattle" for reference to the warble fly will not find any mention of it under that heading, which would make it appear that cattle are not attacked by this insect. Reference to this insect will be found under the heading of "ox," which is not right, as heifers are also liable to the attacks of warbles. The index to unclassified hosts is really not required; only ten "hosts" are mentioned, and they would have been much better placed in one of the other indices; grouse and the excreta of cattle might have found a place in the animal index with much advantage. This "animal index," however, is of little use, for there are only twelve animals mentioned in it, and in three cases the reader is referred to the general index. Though called an "animal index," it should have been entitled "Animal Host Index," for it is only animals that are infested with parasites that really find a place there. In spite of these slight mistakes warm thanks are due to Miss Ormerod and Mr. Newstead for this valuable termination to the first series of these reports. G. S. S.

Gardening Year-Book and Garden Oracle. We expect a book of this kind in the new year, but of course that is the publisher's business. With regard to articles and garden recipes, there is nothing to quarrel with, and the pages are brightened with many illustrations. It is published by Messrs. Colnaghi, 4, Ave Maria Lane, Paternoster Row, E.C.

One-and-All Gardening. We have received this interesting annual for amateurs, allotment holders, and working gardeners, conducted by E. Owen Greening, of the Agricultural and Horticultural Association, 92, Long Acre, W.C. It is a useful book and freely illustrated.

RECENT PLANT PORTRAITS.

THE third monthly part of the fifteenth volume of "Lindera" contains portraits of the following Orchids:

Epilobium elegans. A most beautiful species, with spikes of pure white flowers, the lower petal of which is distinctly spotted with carmine on the inner half of its length, with a deep rosy purple spade-shaped outer portion, which is distinctly margined with pure white. Quite a lovely flower.

Cathaya Loddigesii var. *Harrisonii* subvar. *alba*. This is an absolutely pure white-flowered form of the *C. Loddigesii* var. *Harrisonii* formerly figured in this work, the only trace of any other colour present being the faintest yellow shading of top of lip.

Lalia cubensis. This bears a perfectly upright spike of soft purple-lilac flowers, with deeper purple eye and small white tip.

Cathaya lobata var. *Affodiana*. A fine large flower of rosy purple, veined faintly with white.

W. E. GUMBERTON.

The Netted Iris (*I. RETICULATA*). This flower is charming in pots, and the bulbs seldom fail to bloom in an ordinary greenhouse. The rich blue-purple colour and fragrance of the flowers make this a favourite species. T.

GROUPS OF FLAG IRISES.

In the late May and early June days no nobler flower graces the garden than the German Flag, or Flag Iris (*I. germanica*), so varied in colour and delicate in fragrance. The illustration shows the plant grouped with other flowers, the true way to obtain rich and distinct effect.

GARDENING OF THE WEEK.

KITCHEN GARDEN.

WINTER AND SPRING CABBAGES.

SUCH a winter as the present one shows the value of a good breadth of winter Cabbage, as these being very dwarf growers suffer less in our variable winters than plants with a long stem, and such kinds as Sutton's Favourite and Christmas Drumhead are most valuable, as on removal the snow they are found to be uninjured, and delicious when properly cooked. At the same time, in very severe frosts it is advantageous to lift winter Cabbages and pack them rather close in a frame or cold house, and treated thus the hearts remain good for weeks. The value of these winter varieties consists in their small, compact growth and the long time they remain good when nearly full grown. For use at this season they are best sown in May or early June, according to the locality; on heavy soil I would advise late May sowing. Spring Cabbages, such as Ellam's Dwarf, and Mein's No. 1, are much more forward in growth than usual at this season owing to the late autumn growth which they made, and I fear in some soils there is a tendency to bolting. Of course, the severe weather of late has checked growth, and if previous advice was followed, now will be seen the advantage of moulding up, as this protects the stems, the most vital portion of the plants. With a break in the weather new growth will soon begin, and this will be greatly assisted by using a fertiliser of some kind. We find such aids as guano applied fortnightly excellent, but any quick-acting food will be suitable.

CARROTS.

need a mild bottom-heat to assist germination, which is much slower than is the case with Turnips and Radishes. Avoid thick sowing, as I find severe thinning of the plants loosens those left, and this should be avoided. For present sowing such kinds as the Early Nantes and Sutton's Early Gem are splendid for frame culture, and those who prefer

the short stump-rooted kinds will find the French Forcing, a small-topped variety, very good. Carrots like light rich soils when grown under glass and the soil made firm to assist the roots to bulk quickly. More warmth may be given than to Turnips, so that these roots should have the warmest part of the frame.

TURNIPS.

are well worth glass culture—indeed, in my opinion, more so than Carrots, as last year's Turnips are worthless early in the spring, being flavourless and dry. Little heat is needed to grow Turnips, and the new roots are sweet and serviceable at a time there are so few good roots. Sow thinly and give ample ventilation in the early stages of growth, otherwise there is fear of the plants running. For frame culture I do not know of any better variety than Carter's Early Forcing, an oblong root and of excellent quality. This matures in twelve weeks from time of sowing and should not be forced hard.

FORCED SPINACH.

At times there is a deficiency of Spinach at this season, and now is a good time to make up losses.

the front of the house, and are trained up a trellis parallel with the rafters and fixed about 1 foot from the glass.

Plant 18 inches apart, at the same time nipping off all side shoots, and frequently afterwards go over them for the same purpose, so as to confine them to one stem. The soil must be of a porous nature, so that frequent waterings do not make it inclined to become sour. Loam with quite one-third of lime rubble answers the purpose well. At the time of planting only afford sufficient soil to sustain the plants for a short time, and add to it afterwards, a little at a time, as often as it becomes permeated with roots.

As often as necessary examine the soil to ascertain its state of moisture, and when approaching dryness, afford a liberal application of water. They enjoy a dry, warm, airy atmosphere, and for the present, dry surfaces should only be damped on fine days to prevent dust rising. The temperature may range from 55° as a maximum during the night to 65° in the daytime with fire-heat, with a rise of 10° with sun-heat. Keep ventilation on the apex of the house at all times, except when the

external conditions are of the worst. The quantity must be regulated according to the state of the weather.

Sow seeds to produce plants for planting outdoors at the end of May and give them good attention, so that by that time they may be sturdy and established in 6-inch pots.

STRAW.

BERRIES.

Those plants that have set their fruit may be hurried along in a higher temperature than they have had hitherto, and the swelling of the fruit may be assisted by mixing in the water occasionally some good artificial manure. When they begin to colour afford as much air as circumstances will allow to improve the

colour, flavour, and the solidity of the fruit. From now until they begin to colour syringe in the early part of fine days. A later batch of plants with the bloom-spikes extending will be coming out. Thin out the blooms as soon as the weakest can be nipped out with the finger and thumb, leaving eight to ten of the strongest on each plant. This early thinning is a preventive of waste of energy of the plants. While in bloom, to encourage free setting, maintain a sweet, buoyant atmosphere with fire-heat and ventilation, with temperatures from 50° to 55° at night and 60° in the day from fire-heat.

Take indoors plants for later supplies, and start them slowly into growth as recommended for plants earlier in the season. Green-fly is a troublesome pest in forcing Strawberries, which must be kept in check by fumigation. Richards' XL All fumigating compound is the best remedy for it. It is important to give an application immediately

GROUP OF FLAG IRIS (*I. GERMANICA*).

A few pots of seed sown in frames will make nice material to plant out at the end of March, or seed may be sown in frames as advised for Carrots. The Carter Spinach is the earliest I have grown.

G. WATKINS.

FRUIT GARDEN.

TOMATOES.

Move plants that are strong and established in 5-inch or 6-inch pots into their fruiting pots, or plant them out in houses. Some growers fruit them in pots, thinking they set more freely, but I do not think they do if precautions are taken to guard against over-luxuriance in the early stages when planted out. The labour is considerably lessened when the plants are grown on the latter system. They thrive in either span or lean-to houses providing they have the best position, &c.,

before they come into bloom so that they are clean at the blooming period. Examine the remainder of plants still in their winter quarters so that they do not suffer for want of water. G. NORMAN.

The Gardens, Hatfield House.

ORCHIDS.

THE outside conditions during the past few weeks have not been favourable for disturbing plants which have been waiting for attention as regards re-potting, &c. It is not advisable to disturb anything that can possibly wait while the very severe weather prevails, as any disturbance at the roots considerably affects the well-being of any Orchid. Excessive fire-heat is most detrimental under such conditions, and is, therefore, to be avoided. I advise that all re-potting be postponed until favourable conditions again prevail. The temperatures of the various departments should be allowed to fall almost to the minimum, thereby avoiding any necessity for excessive fire-heat. With lower degrees of temperature the moisture in the atmosphere must be reduced correspondingly, and the damping of the floors, staging, &c., should be deferred until the normal degree of temperature has been resumed. With lengthening days, and the sun's power also increasing, the temperature in clear weather soon reaches the desirable degree, and the necessary atmospheric moisture may then be quickly obtained. Care must also be taken to damp the houses sufficiently early in the afternoon to allow excessive moisture to evaporate before evening with its falling temperature comes on. With low conditions of the temperature in severe weather the plants are not nearly so liable to become damaged if they are retained in a dry condition at the roots. This especially applies to Masdevallias and cool house Orchids. If drier conditions were maintained when low temperatures prevail, I am sure we should not find nearly so much black spot and permanent disfigurement of the foliage as we now meet with where Masdevallias and other cool subjects are grown.

Among imported Orchids now arriving there are none more attractive than *Odontoglossum crispum*. Unfortunately, importations of this lovely species are not likely to be so plentiful as usual this year. The present is a good season in which to procure plants of *O. crispum*, and the earlier the plants are procured the better chance they will have of becoming established before the hot summer weather sets in. This species always sells well, as no Orchid is so much in demand at the present day. The many remarkable forms that have been imported during the last few years have given encouragement to growers of this section, and as these flowers have been considerably multiplied owing to the fact that so many market growers have adopted their culture for cut-flower purposes, and notwithstanding the fact that many large growers have imported direct, the demand has been greatly in excess of the supply, and good prices are thus realised.

In dealing with imported plants, some have a preference for planting them out in a prepared bed consisting of good fibrous peat, sphagnum moss, and a liberal sprinkling of rough silver sand. This is a good system in the case of very small plants, but not one which I should advise amateurs to adopt. When first received lay the plants on a cool, damp bottom for a few days in the *Odontoglossum* house. The shrivelled bulbs will quickly regain a plump condition, and those likely to decay can also be observed. When this has become apparent, clear the plants of all decayed matter and cut away dead roots and bulbs. It is advisable to procure pots which are just sufficiently large to contain the plants comfortably. They should be clean and filled to two-thirds their depth with clean crocks. After placing the plant in position the remaining space should be filled with fibrous peat and living sphagnum moss in equal portions, pressing the compost moderately firm, and thereby securing the plant in position. After potting, the plants should be thoroughly watered, using a rather coarse rose on the water-pot, and they should then be placed in a moist position of the

house where the light is not too strong. Careful attention will be required at first, but as soon as roots make their appearance every encouragement should be afforded. Soft rain water is necessary for the successful culture of *Odontoglossums*; without this they rarely succeed satisfactorily. H. J. CHAPMAN.

INDOOR GARDEN.

YELLOW CALLAS.

CALLAS of the *Elliottiana*, *Pentlandii*, and *aurata* type which may be wanted to flower in April and May should now be potted. If the corms have been well ripened they will be found totally devoid of living roots, and such corms, if big enough, may be depended on to flower well with good treatment succeeding thorough ripening. In potting use good fibrous loam, with a liberal mixture of dry and finely pulverised cow manure, using also a good quantity of sand (either silver or river sand will do), a handful or less of which, according to the size of the corms, should be placed round each one. The corms should be kept well below the surface to encourage the principal feeding roots which spring from the base of the new growth. Place the plants in a house with a temperature of from 60 to 65 and with a moist atmosphere, using the syringe freely. To attempt to grow these yellow Callas in the temperature which best suits the common *Arum* is to court failure, for they enjoy and must have more heat. Very little water should be given until the plants are growing away freely.

ARUMS.

The white Callas, now being in full growth and throwing up spathes, require to be well fed with liquid manure from the stock-yard in a diluted form, and to be kept constantly moist at the roots. A temperature of 50 at night suits them best, but if it is necessary to bring them forward quickly, they will bear more heat, though the spathes will then be less lasting. As fly breeds fast on these plants, vaporise them frequently with one of the nicotine vaporisers in preference to fumigating in the ordinary way, for the use of ordinary fumigating materials browns the tips of the spathes and spoils them.

WINTER PELARGONIUMS.

For winter flowering it is necessary to strike one's cuttings of the zonal section early, and the present is an excellent time to do so. Look out for the healthiest and sturdiest cuttings from plants which have not become drawn, and give each cutting a small pot to itself. Strike in an intermediate temperature in a house or pit the atmosphere of which is dry. Few plants give such a bright effect as these in winter; but all varieties are not alike useful, and I would suggest that old favourites should not be discarded to make room for newer ones with more showy or better formed flowers until the latter have been tried and proved good for winter flowering. J. C. TALLACK.

CHRYSANTHEMUMS.

JAPANESE KINDS FOR EXHIBITION. II.

OVERCROWDING in any stage of their growth must never be permitted, or weakly, drawn-up plants will be the result, and blooms of the finest quality can never be expected from these.

By the end of April it should be safe to transfer the plants to a sheltered spot in the open, standing the pots on boards on the beds, where, if occasion arises, they can be protected with tiffany or some light covering.

The summer quarters for the Japanese Chrysanthemums should be a light, open, sunny position. It matters little whether the plants are arranged on beds or in lines running by the side of the garden walks, but I prefer the latter, as they are more easily attended to and they enjoy a free circulation of air.

FINAL POTTING.

Prepare a mixture similar to that advised for the last potting, except that the loam should be broken up roughly with the hands into pieces about the size of walnuts, and add a 6-inch potful of Thompson's plant manure, one of ½-inch bones, and one of finely broken charcoal to every two bushels of soil.

In my opinion Japanese Chrysanthemums are generally over-potted. Providing the after-watering be well attended to, 8-inch or 9-inch pots should be large enough for the reception of nearly all, except just a few of the very robust kinds, for which 10-inch pots may be used. A thin layer of ½-inch bones should be placed on the fibre for this potting, and if the soil is in a good condition it can hardly be made too firm, which should be done with the potting stick, but a little more fine soil should be shaken over to prevent the soil caking or baking on the top. See that each plant is correctly labelled and a longer stick will be required, to which the plants should be neatly tied. Place them in their summer quarters on boards, allowing a distance of at least 15 inches between each, arranging them in their heights so that the taller plants do not overshadow their neighbours. Stout posts should be driven in at intervals and strong cord should be stretched along to which the plants can be tied.

The plants should not be watered in for a day or two, but may be syringed overhead several times a day during hot, drying weather to prevent them flagging. As soon as the plants require water give them a thorough soaking, filling up the pots at least three times so that every particle of the soil becomes moistened. Watering at all times requires to be done judiciously and thoroughly. Though the Chrysanthemum will take up a great deal of water, much injury accrues through too much being given, and though the plant will to a great extent recover after becoming too dry and suffering much at the time, very seldom will it do so if it ever becomes sodden.

During the summer a thorough syringing morning and evening will be of much benefit. Millew, thrips, green-fly, earwigs and rust are the most troublesome pests to the Chrysanthemum. Frequent dustings in the points with tobacco powder will generally keep at bay the two first named. Flowers of sulphur applied to the foliage when damp will keep down millew, and I know of no better plan than picking off and burning leaves affected with rust. Though there are many advertised remedies, I cannot say much for them. Earwigs can easily be trapped by hanging Broad Bean stalks, about 4 inches in length, about the plants, from which they can easily be blown and killed.

FEEDING.

After the plants become filled with roots, but not before on any account, feeding may commence. This requires to be done with great caution, as though the Chrysanthemum will take up a lot of stimulant, it can easily be overdone. When procurable there is nothing better for this purpose than fresh animal manure, either cow, horse, or sheep droppings. Place a barrow-load of either in a large tub or tank with one bushel of soot tied up in a bag, and add about 150 gallons of water; this forms a good safe manure. It should be stirred up and used at every other watering, diluting it to about the colour of weak tea. By way of a change a small quantity of ichthonic or Peruvian guano may be given, which is best applied in showery weather. A dessert-spoonful is ample for each plant, which should be shaken evenly all over the surface of the soil.

TIMING AND SELECTING BUDS.

To have the whole of the flowers in perfection at one time of course many of the varieties will require pinching. The first bud is generally formed during May; this is called the break bud, because the plants break away into new growth immediately the bud is formed. The three strongest shoots should be retained and the others rubbed out. In about three months the shoots produce another bud, which is called the crown bud. In a few instances of late varieties this bud should be secured, taking out the whole of the shoots which

appear around it. This will generally be early in August. Unfortunately, many of the best varieties do not come clean and of good colour from this bud, so that special means should be taken to induce second crown buds to form early in November, and to obtain this the points of the shoots must be pinched out from the last week in March to the second week in April, unless the plants break away naturally, when they should form buds about the middle of August; but experience alone can make one perfect in this. The whole of the buds should, if possible, be secured by the middle of August, as any that form after this date are usually too late for the November shows.

HOUSING THE PLANTS.

The plants should, if possible, be safely housed by the end of September in light airy houses. Abundance of air should be given day and night until the plants become acclimatised. Avoid overcrowding, or the loss of foliage will be considerable, and this should be retained as much as possible until the plants have done flowering.

AMERICAN PERSIMMON (DIOSPYROS VIRGINIANA).

Arrange the plants in a pleasing manner, according to the shape of the structure. During the time the plants are unfolding their flowers weak manure water should be given at every second watering, and the plants should be thoroughly fumigated every ten days. Always water in the early morning, and the Chrysanthemum is much benefited if the hot-water pipes are kept just warm. This will prevent damping and assist the better development of the flowers and also the coloring. Fortunately, Japanese blooms require but little dressing to make them presentable on the exhibition stage. Damped or badly formed florets should be removed, and green eyes, if any, carefully taken out with a pair of forceps. Unquestionably the new and pleasing way of showing these in vases will before long be generally adopted. E. BECKERI.

Albion House Gardens, Elstree.

PERSIMMONS.

A LETTER FROM AMERICA.

I was surprised to see the Japanese Persimmon (*Diospyros Kaki*) referred to in a recent number of THE GARDEN (p. 29) as the Date Plum. It is not a Plum in any sense of the word, and not related to the Plums. This name is the more misleading, since the Date Plum is really a variety of the common domestic Plum, long known and cultivated in Europe, and described in nearly all the common works on pomology.

The Persimmon is not uncommon, though still not a popular fruit, in the United States. There are several varieties propagated by certain nurserymen who make a speciality of this fruit, and a few collections and small orchards are in bearing. Small offerings of these Kakis are generally to be found in the city markets during autumn, but they are sold at a somewhat fancy price, and there is no general call for them. The Kaki is a beautiful fruit and fit to grace any table. It is desirable, not only on account of its novelty, but for its intrinsic good quali-

ties, as a dessert fruit. It is well worth more general cultivation in amateur collections, and ought to make a larger market for itself at the fruit stands.

The native Persimmon is less often cultivated even than the Japanese varieties, though it has some points of superiority. The principal advantage which it enjoys is in its better quality. The fruit is richer and more sugary. Well-ripened Persimmons are very agreeable to many palates, especially to those cultivated somewhat to that taste. There are several named varieties of this native Persimmon (*Diospyros virginiana*) handled by American nurserymen. They are mostly propagated by grafting them on seedlings. The Japanese varieties also are often grafted on the native seedlings. The greater part of the Persimmons which are eaten in this country, however, are those gathered from the woods. The wild trees, too, are the principal source of supply

for the markets. A certain quantity—nothing very large, however—is always seen on the fruit stands. The photograph which I am sending you herewith is taken natural size from specimens gathered at random off the wild trees of Maryland in January. These fruits were just in condition for eating. To my taste they were delicious.

Burlington, Vt., U.S.A. F. A. WAUGH.

FALSE IDEALS.

Though I agree with much that your correspondent "S. W. F." writes on this subject, I cannot help feeling that he might have been a little less sweeping in his condemnation of the practice of clipping evergreens. It is quite true that excessive formality should at all times be deprecated, and that it is mere vulgar affectation on the part of the owner of a garden to endeavour, by the introduction of an abundance of evergreen balls, squares, pyramids, and peacocks, to impose on himself, or his friends, the absurd fiction that his garden was laid out in the reign of Queen Anne, and that it has remained so ever since; nevertheless, there is much to be said in favour of well-clipped hedges of Yew, Box, or Holly.

A garden after all is a garden, that is, an enclosure made by man, a place fenced in from wild Nature for a man's private use and enjoyment. It must have walls and hedges, or boundaries of some sort. It is a very delightful and commendable practice to naturalise beautiful flowers in meadows and wild coppices; it undoubtedly adds to their beauty and interest, but these places cannot strictly be called gardens all the same. In a garden, evidence of the work of man, *as long as such work is controlled by good taste*, is no detriment and need never be concealed. Lawns are none the worse for being kept smooth and velvety, paths for

being firm and free from weeds; strong comfortable seats are not eyesores, fountains are at times desirable; a pergola shade or a well-designed summer-house for tea or shelter does not necessarily injure the general beauty. And in the same way a well-clipped hedge *in its right place* adds not only a comfortable feeling of home to the garden, but assists much in the general beauty as a foil. Artists know well the immense value that broad masses of evenly-graduated neutral tints have in the composition of a picture. They carefully avoid cutting up this breadth with detail of positive colour, or light and shade. The detail and interest of the "jewellery" of the picture is enhanced immeasurably by the quiet relief of these breadths of even neutrality. It was well said of Macaulay that he knew how to adorn his conversation by occasional brilliant flashes of silence.

A well arranged herbaceous border never looks better than when it has such a quiet backing as the exquisite dark olive a clipped Yew hedge affords; much of the beauty is lost, escapes as it were, if the flowers are allowed to get mixed up with the background in a wild way, or if the background has a distracting effect by too much detail of colour, light and shade, or even beauty of its own.

I think that every garden of any size should have at least one dry sheltered path with a sunny aspect; a harbour of refuge for the invalid or the aged, for use in the cold spring or autumn, and nothing answers so well the purpose of such shelter as a hedge of well-clipped Box, for it has no overhanging boughs to injure the path by drip or falling leaves, and the delicious scent of the Box-leaves in the sunshine makes it, in my opinion, superior for this purpose to a wall, even though when beautified by age.

A wise little girl that I knew, when asked which of two nice things she preferred, invariably answered, "Both." And in this much vexed question of the natural *v.* the formal arrangement of gardens, surely the happy medium is the most desirable. A little more of the one or the other, according to the predilection of the owner, is quite right at all times, so as to secure individuality, which, after all, is ever most important, for a man's garden ought to be quite as much in keeping with his character and personality as his house and home. A man with no taste of his own who merely follows the fashion, no matter what the fashion may be, or who leaves everything to his gardener, cannot be said to have a garden of his own. He relegates the piece of ground to another, and then it all depends on what amount of taste his gardener has. In most such cases the results are commonplace and conventional. G. D. LESLIE.

A TOWN GARDEN.

Few things are more depressing to the average man than the dismal aspect of a neglected back-garden in a town of considerable size. Such a plot came under my notice not long ago, and under judicious management and careful arrangement it has in a very short time proved such a pleasure, that I think some details may be of use to those who find themselves possessors of such a potential "Eden." As is usually the case in all ordinary town gardens, the area is about three times as long as it is wide—in this case containing quite a third of an acre—surrounded by sooty brick walls devoid of any climber whatever. The ground is quite flat and the soil strong clay, which, however, had once been well worked. On the ground stand two dilapidated and dark old

glass-houses; one ainery facing south with a somewhat raised Vine border long disused; the other house, a span roof, near the eastern wall of the garden. A few poor trees outside at one corner give the only touch of greenness to the space within.

The first idea, to cut up the ground into three squares, one for flowers, one for vegetables, and one for reserve ground, was abandoned, both on account of its ugliness and also because it did not afford scope for a grass walk with flowers at each side and a seat in shelter, which was the cherished wish of the new possessor. At last it was decided to make a broad gravel walk across the width of the garden at the far end, and heighten the old Vine border so as to obtain a southern slope. The entrance to the garden is at the south-west corner, and the greenhouse stands midway on the eastern side, projecting into the ground. This afforded an opportunity to destroy the formality of the long strip by making a broad grass walk from the entrance diagonally across the ground into the angle between the greenhouse and the garden wall. This walk, 7 feet broad, was sunk quite 3 feet into the ground by the steps at the entrance, and rose gradually to the ground-level at the other end. The clay and soil taken out was used to raise the beds on either side and make an even slope to the path as it rose to the level. At a distance of about 12 feet from the grass path a hedge of *Olearia Haastii* and red and white double Japanese *Rosa rugosa* was planted to screen off the reserve and vegetable plots from the decorative part of the garden. By this means two broad borders were obtained having different aspects, and at the upper end a very warm and sheltered corner was formed for tender plants, while at the lower end by the door two fair-sized triangles were dug out of the clay to form a drainage to the sloping walk, and at the same time afford a moist and shady nook where some hardier bog plants and flowers might thrive.

Towards the upper end a narrow gravel path was cut through the bank round the end of the greenhouse which joined the broad terrace walk at the foot of the Vine border, and afforded on the side near the greenhouse a suitable place for a seat where the flower borders might be seen. Four Bay trees in tubs (which find shelter in winter in the disused inery) protect the seat from the neighbours by means of striped awnings tied from stem to stem.

After this rough blocking out of the flower garden the next thing was to plant it, and to harden one's heart against unsuitable things, however lovely and desirable they might be in themselves. I am not sure that in the long run there is not some advantage in being unable to grow many things, as the best effects are always attained by simple means.

Roses are forbidden in a town garden except the invaluable *Rosa rugosa* and its varieties, but the new and extra vigorous *R. Wichuriana*, which is not well known as yet, seems to promise great things. Its corymbs of sweet white little flowers in August and September are most delightful, and its glossy neat foliage an ornament to any garden. Conifers too are quite useless, and so is any evergreen that looks sooty and black like some varieties of the Holly.

On the other hand, Carnations and Pinks thrive extremely well, so broad masses of them adorn this walk, and a bed of seedlings in the reserve plot affords a long succession. Yuccas, Tritomas, Lilies and tall composites form a stately background to the usual semi-hardy bedding plants and annuals, and Sweet Peas, Mignonette and Sweet Geraniums afford, with *Ceropepis* and various composites, plenty of bloom for cutting, even though their fragrance

may not equal those grown in country air. Irises of all sorts, and especially Gladioli, are as happy as possible, and Dahlias are bright and useful till the sun gets hidden behind the tall houses near and causes an early collapse in autumn.

The walls of a town garden are always a trouble. In this instance they were so dimly sooty and black, that the only thing to do was to whitewash them all; and a precious business it was to obtain anything like a clean surface! But no sooner was it done than the way the plants responded to the increased light and lessened dry baking heat in the summer was wonderful, and proved it was the right thing. Trifles can make or mar, and I am inclined to think this trifle made a great deal of the success in this town garden.

There is one decided advantage in a town garden, and that is the greater freedom from frost, so that many shrubs will live there that would perish in frostier situations. So the walls where the sun lingered longest were planted with *Choisyas*, *Laurustinus*, *Jasmines*, variegated *Euonymus*, *Escallonias*, and many another flowering shrub and climber, including *Clematises* in variety, and they are all doing well and looking as they should do—ornamental.

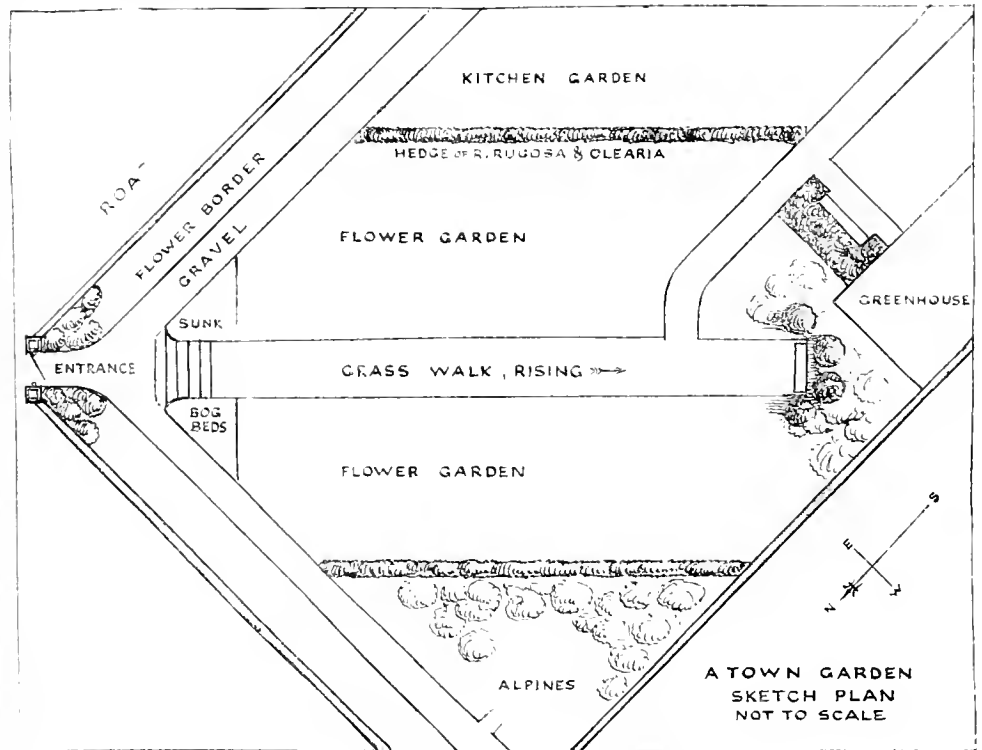

The plague of caterpillars so common in town gardens in the early autumn does not affect any of these. On the shady sides, the simple plan of planting tall Oval-leaved *Privet* and sowing climbing *Nasturtiums* to climb over and

THE FLOWER GARDEN.

GIANT MIGNONETTE

GARDEN AND POT CULTURE.

PROBABLY no greater disaster could befall our summer gardens did any unforeseen circumstance render necessary the expulsion of this beautiful, popular, and fragrant race of plants, as nothing else could replace it or fill the tremendous gap that its loss would undoubtedly cause. Too frequently we look upon these common ornaments of our gardens without adequately realising half their worth, and how much our gardens owe to such a unique and easily accommodated plant as Mignonette. The keenest gardeners and garden lovers of to-day are too often satisfied with a solitary spray of one of the several excellent forms of this giant strain. How unceasingly is the plant regarded with the greatest admiration, largely brought about by the fragrance that is itself unique. In many kinds of garden flowers the mere increase of size has not brought in its train an increased number of admirers, nor, indeed, has it enhanced the value of the plant. It is, however, quite the contrary in the case of these giant strains of Mignonette, some of which are quite a revelation when compared with the older types and forms, while, as judged by the standard of modern improvements, it would appear in size and uniformity at least to have come very near perfection. Happily, too, these larger forms present no greater cultural

between was of course adopted, and *Aucubas*, *Aralia Sieboldii*, *Megaseas* and *Frankias* formed handsome masses of solid foliage, till in two years' time this garden has become as full of interest and beauty as it was desolate and barren before, and a wonder to those whose knowledge was not equal to their love.

E. H. WOODALL.

Winter flowering of Yuccas. The flowering of *Y. gloriosa* in winter is not untimely. It is so much the habit of the plant, that when Evelyn described it he classed it with *Snowdrops* as a December and January flower.—H. ELLACOMBE, *Bitton Vicarage, Bristol.*

difficulty than the commonest types in vogue, and herein is a value not lightly to be estimated. As to the accommodating nature of the plant, and the almost endless variety of uses to which in any garden it may be put, none know better than those devoted to its culture. I say accommodating, not as the term is usually applied to many annuals, referring to the way in which they will readily transplant, being hardly affected by the operation, but rather from its quick responsive action when raised from seed. In this way, with knowledge and good seeds, it is possible to regulate its flowering to a very considerable degree, which is often convenient for various reasons. These giant forms, indeed all the kinds, may be sown at intervals from February till early in July, according to the needs

of individual gardens. As a mixture among the beautiful Tufted Pansies, as a sort of groundwork to many things, as a stop-gap here filling in odd corners, or there as a covering where spring bulbs have just held sway, the fragrant Mignonette is always useful. It has also a value in those places "where the honey bee sucks," and may, for purely economic reasons, be planted freely as a counter attraction, keeping the honey seekers from choicer things. A year or two since this had to be done to attract the swarms of bees that were bent on entering a big house containing some thousands of plants of the deep crimson Carnation Uriah Pike. Being a highly fragrant flower, the insects were quickly attracted, and in a few days such havoc was wrought by the swarms that came, and that increased day by day, that all doors, ventilators, and the like had to be covered with canvas screens. The following year the Mignonette saved much of this trouble and anxiety.

A moderately deep and good soil is suitable, and in heavy soils old mortar rubbish is very beneficial. Being largely tap-rooted, or in its early days inclined that way, Mignonette is not so readily transplanted as many things, but if transplanting is not possible, its equivalent must be found somewhere. It is most usual to sow it almost as thickly as Mustard and Cress, but in so doing the giant heads stand a good chance of being lost. A capital plan where isolated plants are needed is to put a couple of seeds in a 2½-inch pot and transplant boldly where they are to remain. This may also be done when very early bloom is required, as not infrequently the seeds perish or are discovered by mice. In sowing broadcast they should be sown thinly and the seedlings thinned early.

For pot culture the giant strains are those finding the most favour, one to four seeds being sown in each pot. Two-inch pots are the most serviceable, and the plants are thinned to the best one when large enough to handle. This one has its point taken out once, and the resulting five or six breaks that follow are allowed to carry one head each. In some instances the plants are sown in boxes and transplanted when quite small, half-a-dozen in a 5-inch pot, but in bad weather there is much damping of the stock so treated. Here again the single pot system has its advantages, for not only is the plant boldly transferred to the larger pot without loss of roots, but it has also been an isolated plant from the beginning. To attain perfection in pot culture of this beautifully simple flower, a rather long season with quite cold treatment is absolutely necessary, as anything approaching close, stuffy, or heated quarters quickly elongates the plants, and thereby minimises the chances of success. Cold, very shallow, and very airy frames are the best, with sowings at intervals. Good heavy rather than light loam, old cow manure finely sifted, and mortar rubbish from a good compost, and firm potting is advisable. E. JENKINS.

TUBEROUS BEGONIAS.

This beautiful class of Begonias has been so much improved both in habit and the form of the flowers—the colours, too, are so bright and varied that it seems almost impossible to make much further advance. It must, however, be remembered that to keep them up to the present standard of excellence great care must be exercised in selection for seeding and also in proving them. In some instances named varieties may be worth retaining, yet as such splendid results may be obtained from seedlings, these may be relied upon, except for the specialist. The great advantage of seedlings is that the second year they make better plants than those propagated from cuttings or those grown from old corns.

Seeds sown now will make nice plants by the autumn, and if planted out in the open they will flower early enough to make a selection of the best for growing the following season either for bedding or for pot culture. The very finest should be selected for pots, and those intended for bedding should have the colours marked, and as they vary in habit of growth, if some attention is paid in regard to height, &c., it will be a guide in planting out.

I was much surprised to find during the past season that many of the older and inferior type were grown by those who wish to display their skill in cultivation, as seeds or corns may be obtained at a moderate outlay, and if from a good source they are sure to be a great advance on the older types. Not that I wish to say the enormous flowers are to be admired most, but those with medium sized flowers and stiff erect flower stalks certainly show up better than those with long drooping flower-stalks; of course to some extent it is a matter of taste. Culture also goes a great way in regard to producing satisfactory results; I find so many growers give them too much shade and not sufficient air when growing them in pots. When under glass they require sufficient shading to break the bright rays during summer, but this should be only during the time that the sun comes in direct contact with the plants.

They like rather more root room than some other plants, yet it is not necessary to go too far in this direction. If a good rich compost is provided and a liberal supply of manure after the pots are filled with roots, much better results will be obtained than by over-potting. After they are well established they take up a good supply of water, but when first started great care should be taken not to get the soil too wet. Although varieties have been so much improved, the cooler and more exposed method of culture has done much towards developing the fullest beauty in this class of Begonias.

A. HEMSLEY.

NOTES OF THE WEEK.

Scilla sibirica under glass.—Pots of this charming little Scilla are just now very attractive in the greenhouse where flowers of a white or light tint predominate. The delightful blue of the Scilla affords a pleasing variety to the occupants of that structure, for although there are many blue Hyacinths, the particular pleasing blue of the Scilla is not represented among them. Like several other early-flowering bulbs, this Scilla must not be forced hard, but simply assisted with a little heat, such as the temperature of a greenhouse, in order to induce it to flower earlier than would be the case out of doors. T.

Fruiting of Euonymus japonicus.—I notice a paragraph on page 55 mentioning that in the Isles of Scilly and also on the southern shore of the Isle of Wight this Euonymus has fruited. This occurrence has not been limited to these detached fragments of our southern coast, for on the mainland, in South Devon, the same has been observable. Some years ago in the same locality these bushes showed fruit, but not so plentifully as during the present winter. *Pyrus (Cydonia) japonica* has also been unusually prolific, many specimens bearing quite a heavy crop of large, apple-like fruits. S. W. F.

Shrubby Veronicas. Many shrubby Veronicas of varied colours are flowering, and have a pretty effect drooping over a high retaining wall. In the severe weather of the early part of 1895 many of the old bushes perished, but the young plants grown from cuttings struck in the open ground some months previously, and which had not at that time been removed from the cutting bed, survived the winter without injury. With such subjects it is therefore advisable to strike a batch of cuttings every year, so that the places of any that may happen to be killed may be filled by the young plants. S. W. F.

Narcissus pallidus præcox. In answer to the suggestion in Mr. Arnott's note (p. 106) that others who grow this beautiful Daffodil should say how it does with them, I may mention that soon after Mr. Barr's first importation it was tried here, first in very light, but well-worked garden ground. But, in company with all the whiter trumpets, both of the species and the fine garden kinds, it showed only a steady deterioration. After seven years of growth and two shifts—we shift them every three years in this garden—the small stocks were so much reduced, that, as a last hope, they were planted out in the poor shallow

soil of the copse. Here the few bulbs of pallidus præcox seem quite happy, and are pictures of health. The whites, also, are doing well. The soil of the copse is thin and sandy, and only enriched by a skin of peaty leaf-mould 1½ inches thick, and covered with a sparse tussocky turf of wild Sheep's Fescue Grass. Below the upper 4 inches are beds of hard sand and rock for 200 feet down, where a water-bearing stratum occurs. G. J., *South-west Surrey.*

Acacia Drummondii.—Among the numerous Australian Acacias that are met with in our gardens this Swan River species is one of the most popular for growing into small specimens, for many of them will not display their beauty when grown only in a 5-inch pot. Under such conditions, if stopped freely during its earlier stages, this will form a neat, compact bush, whose somewhat ascending branches are clothed with pinnate leaves of a deep, yet pleasing, shade of green, while the pale yellow flowers are freely borne in drooping cylindrical spikes. It is by some cultivators grown as a standard, and has a decidedly pretty effect when treated in this way. *A. Drummondii* needs a soil principally composed of sandy peat, and the plants should in all stages be potted firmly.—T.

Mutisia decurrens.—This climber was figured in THE GARDEN many years ago—as well as *M. Clematis*—but is rarely spoken of. There is a plant of it growing at Kew, on the front of the museum facing the ornamental lake, which I have once seen in bloom. I should like very much to be able to grow it. Perhaps someone who possesses it may kindly give a few notes about it. The chief thing I can glean is from a note on it by the late Shirley Hibberd. He says it requires the least attention of any climber known. This sounds promising; nevertheless, I failed to keep one plant I obtained. There are few climbers with flowers of such a brilliant orange colour, and I feel sure that it would become very popular if it really can be managed as a hardy plant. T. J. W.

The Tasmanian Laurel (Anopteria glandulosa). For the sake of its foliage alone this greenhouse shrub is well worth growing, as its glossy deep green leaves are regularly serrated and very handsome. They are ovate in shape and about 6 inches long. The blossoms are borne in erect terminal racemes, and the earliest are just now expanding. They are white, cup-shaped, and about ½ inch in diameter, being in general appearance a good deal in the way of individual blooms of *Clethra arborea*, but larger. Though it can be obtained from most nurseries where a collection of plants is grown, this *Anopteria* is rarely seen in gardens. This is, perhaps, to be accounted for by the fact that it is by no means readily propagated, and its rate of growth is slow.—H. P.

Clematis indivisa.—The first of the pretty white-starry blossoms of this New Zealand Clematis are just expanding, and for a couple of months or so under favourable conditions a succession will be kept up. The long loosely disposed sprays when laden with blossoms form a most attractive feature in the greenhouse, and stamp it as one of the best dozen climbers for that structure. In the typical kind the thick dark green leaflets are quite entire, but in the variety *lobata*, which is more often met with than the type, they are distinctly lobed. This Clematis is rather liable to be attacked by mildew, to obviate which as far as possible care should be taken to have the border in which it is planted well drained, and this, together with a free circulation of air in the structure in which it is growing, will do much to combat the evil. H. P.

Forced Daffodils.—Accidentally I discovered a way to help to keep down the ever-growing labour bill and to get a better result with forced Daffodils, and probably some of your readers may be glad to follow my plan. Early in December a few years back I had to take up a lot of Tenby Daffodils, and, not wishing to throw them away, they were just crammed into boxes; the smaller clumps were put into 4-inch pots, and the whole lot placed in a warm frame. To my surprise they did not object to this rough treatment at all, but came on ahead of the others, which had been carefully potted in July, and gave a splendid lot of

bloom. Ever since then I have repeated the experiment, and am now satisfied that much better results can be obtained by this rough-and-ready treatment than by selection and potting the best single bulbs at the usual time. As I write I have before me a 4-inch pot containing a clump of *N. Harpur-Crewe* with nineteen expanded flowers and strong foliage; another pot of *N. princeps* has nine handsome flowers. Certainly this spring I shall mark many varieties for lifting in this way in November and December next, and I strongly recommend those of your readers who wish to steal a march on the Daffodil season to do likewise. — A. KINGSMILL, *Harrow Wood, Middlesex.*

Hyacinthus azureus. To one who has often referred to the charming little plant now known by this name it is a pleasure to see that Mr. Tillett is also able to speak favourably about it. It is one of my favourites among the earliest of our flowers, and it always seems incomprehensible to me why so few know it or grow it. Its great drawback in some gardens is the liking slugs have for it. This liking may be overcome with a little care by the application of the zinc or brass woven wire rings to which I referred in *THE GARDEN* a short time ago. As Mr. Tillett says, this plant seems to delight in being left alone—save, of course, with regard to the precaution suggested. It does not increase rapidly at first, but when left alone its multiplication by offsets becomes more rapid, and the grower is rewarded by the pleasure afforded by a clump of its little clustered heads of pale blue. I like, also, to look after it in changeable weather in winter, when successive rains, frosts, and thaws are apt to rot the flower-stems at the base. — S. ARNOTT, *Carssthorpe, by Dunfermline, N.B.*

Lachenalia Nelsonii. Those readers who have not yet grown this useful winter-flowering plant I would strongly recommend to do so. They are very effective in a mass of four or five 6-inch pots arranged in a rustic irregular vase with a very light plant of *Cyperus laxus* in the centre. Both these plants are fairly hardy, and will even stand in a cool hall where it would be unwise to stand more tender material. I have just removed such an arrangement from an entrance hall, which has been a great attraction for the past two weeks. The yellow bells are very showy at this season of the year. I pot up my bulbs in early August, using open turfy loam, a little leaf-mould made porous with coarse sand or small opening burnt material, adding a little dry cow manure rubbed through a $\frac{3}{4}$ -inch sieve. The bulbs are arranged in the pots about 2 inches apart if strong, and closer if small, covering them about 1 inch deep. The pots are nearly half filled with fine crocks and stood in a cold frame, and are only removed from there to other cool quarters when severe frost occurs. To get strong flower-spikes, do not coddle them. — JAMES R. HALL, *Fox Warren.*

Early bulbous Irises. A very large proportion of the best of the bulbous Irises are now in blossom here in open ground; they cannot be commended too much for this season of the year. I. Danfordie, I. Bakeriana, I. persica Vogeliana, I. Histrio, and I. histrioides. Iris reticulata will very soon put in an appearance. H. EWANK, *Ryde, I. of Wight.*

Stocks in flower now. Everyone appreciates Stocks, whether grown in the open or otherwise, and for pot culture in spring they have much to recommend them. They are far more precious grown in this way than many things that need a lot of heat to bring them on. Those who have unheated glasshouses should make a note of these and give them generous culture. They need little attention through the winter other than watering and giving air, and in the spring pots of sweet-scented flowers will be available for placing in rooms, conservatories, or to cut from for vases. Added to this they lend themselves for cutting to send away better than many things. Seed is sown in May, and the seedlings pricked out on an open site. In September they are taken up, potted three in a 7-inch pot or one in a 5-inch one, placing them either in a cold frame or on a shady border until established. They are

then removed to a sunny position and allowed to remain till severe cold comes, when they are placed in a cold frame or house for the winter. If they are removed at the beginning of the year into slight heat they soon bloom. At the present time (the second week in February) we have long sprays of the variety Princess Alice in bloom. These kinds, East Lothians and Intermediates are excellent for this purpose. I remember the fine scarlet Intermediate I used to see in London shops in April and May twenty-five years ago, also a Wallflower-leaved kind at Diddington Hall thirty years ago, grown in this way. — J. CROOK.

Winter Aconites. As a lover of the little Winter Aconite, I have read with much interest the note by Mr. G. D. Leslie on page 81. I have often thought it strange that no variation in the colour of *Eranthis hyemalis* existed so far as I could ascertain. This seemed to me rather wonderful in a plant which is so freely reproduced from seeds, and which one would have thought would have sported into a few shades of yellow long ago. I have a fairly good acquaintance with the works of the old writers on hardy flowers as well as some knowledge of the work of the present day among them, but until I read Mr. Leslie's note I was unaware of anything but one colour, or rather shade, in one of my favourite flowers. I hope your correspondent will succeed in his endeavour to increase the variety he has succeeded in raising. — S. ARNOTT, *Carssthorpe, by Dunfermline, N.B.*

Begonia Gloire de Sceaux. This is a grand Begonia for flowering during the early months of the year; indeed, it is in beauty just as the universally grown Gloire de Lorraine is in many instances past its best. The variety Gloire de Sceaux was sent out by Messrs. Thibaut and Keteleer, of Sceaux, France, during the year 1887. It was by them announced as a hybrid between *B. socotrana* and *B. subpeltata*, but its general appearance does not suggest that *B. socotrana* was one of the parents. Whatever doubt may exist as to the parentage, there can be no difference of opinion as to its great merit and value where a supply of flowers has to be maintained all the year round. It forms a stout, vigorous-growing specimen, well furnished with ample foliage of a thick texture and rich metallic tint. The flowers are of a pleasing shade of deep pink, and are profusely borne in large clusters. For the last few years it has been steadily gaining in popular favour. — T.

Erica Wilmoreana. This is one of the few Heaths that have remained popular as market plants for the last thirty or forty years, and such being the case, its ornamental qualities are of course of a high order. It is somewhat in the way of the universally grown winter Heath (*Erica hyemalis*), yet they are sufficiently distinct to be readily distinguished. *E. Wilmoreana* is, however, of a more spreading and robust style of growth than the other, while it is at its best as a rule in February and March, at which time *E. hyemalis* is nearly, if not quite, over. It is also rather less exacting in its cultural requirements than *E. hyemalis*, yet the cheap rate at which grand little flowering plants of both can be bought in the streets of London show that some cultivators at least can grow them with but little trouble. Both the above-mentioned Heaths are regarded as garden forms, yet their origin and early history seem to be unknown. They belong to what is popularly known as soft-wooded Heaths, which term is applied to those kinds that can be readily increased by cuttings of the young growing shoots. — H. P.

Deutzia gracilis. As a dwarf free-flowering shrub, particularly in sheltered spots in the open ground, this *Deutzia* scarcely has its merits recognised, probably owing to the fact that, being so generally employed for flowering under glass, any other method of utilising it is left out of calculation. Just now forced plants of it are very attractive among the many hardy shrubs subjected to the same treatment. By some cultivators it is for this purpose kept altogether in pots, and by others lifted from the open ground and potted during the autumn. Those that are confined altogether in pots respond more readily to an

increased temperature, so that for the very earliest they are decidedly preferable. If lifted and potted this operation should be carried out as early in the autumn as possible, even before all the leaves drop, as in this way the roots quickly become active, and they are at least partially established by the end of the year. *Deutzia gracilis* is also of special interest from the fact that it is one of the parents, *D. parviflora* being the other, of *D. Lemouinei*, which differs from *D. gracilis* in being of stouter, straighter growth, while the comparatively large pure white flowers are disposed in a more flattened cluster. It is a great acquisition to forcing shrubs, but unfortunately seldom flowers in a satisfactory manner in the open ground, being under such conditions generally a disappointment. After flowering, these *Deutzias*, whether grown in pots or in the open ground, should, like many other shrubs, have the old and exhausted wood cut out in order to allow the young and vigorous shoots to develop. — T.

Moræa iridioides var. Macleaii. — The superb form of *Moræa iridioides* which appeared in the last issue of *THE GARDEN* (page 123) as a drawing in black and white, by Mr. Moon, from a plant in Mr. Kingsmill's garden, deserves special mention as it is so far superior to the type plant, figured in vol. 19 of the *Botanical Magazine*, that it would appear to be a different plant, though to botanists it is identical. The size of the flower, brilliancy of colouring, and long continuance of blooming render it a precious gain for the cool greenhouse where plants other than the usually found occupants are appreciated. The type I have grown for nigh twenty years, but this lovely plant has only recently come under my notice. — J. T. BENNETT-POE.

Notes from Ireland. The weather for the past fortnight has been decidedly unpleasant. The sharp touch of winter will probably upset all forms of vegetation. Ten degrees of frost (Fahr.) were registered on the grass. In spite of this, one can occasionally discern the pendulous blooms of the Snowdrops under the shade of shrubs and trees peeping above their snowy vesture. The Christmas Rose, too, enlivens the scene. In the mountain gardens of Lord Massey at Killakee it, however, simply revels, being one mass of bloom. The modest Violet still lingers, and strives to bloom amidst the un congenial surroundings. The evergreen and deciduous subjects are in many situations clothed in the fleecy gown of winter; the Holly berries, too, have been bereft of their fruits by the flocks of thrushes and blackbirds. The Rhododendrons are likewise in a sad plight, the frost having destroyed the early flowers. — A. O'NEILL.

Crocus Sieberii and C. Olivierii. With reference to Mr. Arnott's interesting note on *Crocus ancyrensis* in *THE GARDEN* for February 10, I should like to mention two other early Crocuses which have been delightful here during the recent spell of bad weather, viz., *Crocus Sieberii* and *C. Olivierii*, both, I believe, from Greece. They have struggled nobly against the snow, and (mainly, I think, because they are dwarf) have at length been rewarded and are fully open to-day. The orange-yellow of *C. Olivierii* is extraordinarily rich and pure. *C. Sieberii* has a peculiar mauve shade, which I can compare with no other colour, and a distinctly silvery sheen. At the base of the perianth is a yellow patch. Another year I hope to grow these early Crocuses on a rock bed or a raised border under a handlight with a movable top, as I have done this year with *C. Imperati*. It has been a real pleasure during this last week to go out in the morning, lift up the glass, and find a brilliant patch of *C. Imperati* with the snow all around 8 inches or 9 inches deep. What a pity it is that one sees this *Crocus* comparatively seldom in gardens. Can you, or any of your readers, tell me whether this species (*C. Imperati*) varies to any great extent? I am puzzled by one now in flower, received last year from M. van Tubergen, jun., of Haarlem, of which the inner segments are much redder than usual, while the dark blue feathered stripes on the outer buff-coloured segments are absent. The style-branches are almost crimson and in much stronger contrast with the yellow anthers than is the case in the type. — F. N. A. G.

SEEDS.

As soon as the new year dawns, the thoughts of the gardener are turned towards another year's planting, and the question crops up in his mind, "What varieties of vegetable seeds shall I plant this year?" Catalogues are obtained, and he becomes lost in the multitude of the varieties of seeds, all of which, according to the account, are just the kind to grow in his particular garden. This stupendous task will not be so difficult to anyone if the facts are looked fairly and squarely in the face. There are two important points to be considered: first, the extent of the purse; secondly, whether it is intended to go in for prize-winning or not. Should the financial part not affect the question, then by all means go in for the best and latest varieties of seeds; more especially is this necessary when exhibiting is the aim.

Where economy has to be studied and exhibiting is not gone in for, there are plenty of seeds of what one may term "standard fame" which are excellent in quality, but having been introduced a few years are not the "latest up-to-date," and in consequence of this are much cheaper, and therefore suited to those of small means.

Most seedsmen supply an order list with their catalogues, which saves time and labour to the buyer; this should be filled up in ink and sent in early, as the best seeds go first. It would be better to put the items down roughly first, and if the amount totals up to more than the sum intended to be expended, it can be easily cut down where necessary.

As a guide I give a list of what I consider to be the best varieties of vegetable seeds both for ordinary and exhibition culture:

	STANDARD KINDS.	FOR EXHIBITION.
Peas	American Wonder (E.)	Little Marvel (E.)
"	Boston (M.)	A. I.
"	No-Plus Ultra	Centenary Marrowfat
"	"	Best of All (M.)
"	"	Eureka (M.)
"	"	Late Queen (L.)
"	"	Latest of All (L.)
Dwarf Beans	French No-Plus Ultra.	Perfection.
Broad Beans	Canadian Wonder	Veitch's Foreign.
"	Green Windsor	Exhibition Longpod.
"	Green Longpod	Green Giant.
Scarlet Runners	Old Scarlet	Best of All.
"	Champion	A. I.
Potatoes	Victor (Sharpe's)	Up-to-date.
"	Ashleaf (Myatt's)	Satisfaction
"	Magnum Bonum	Snowdrop.
"	The Bruce	Schoolmaster.
Beet	Bell's Crimson	Blood Red
"	Turnip-rooted	"
Borecole	Cottagers	A. I.
"	Dwarf Green	"
Brussels Sprouts	Aigbunth	Exhibition.
"	"	Matchless.
Cabbages	Earfield Market	Earhest (E.)
"	Early Market	Favourite (M.)
Savoy	Gen	Earliest of All
"	Drumhead	"
Cauliflowers	Early London	First Crop.
"	Walcheren	"
Carrots	James's Intermediate	Early Gen
"	Early Scarlet Horn	Favourite
Cucumbers	Telegraph	Favorite
"	Covent Garden	Improved Telegraph.
Celery	Superb Red	White Gen.
"	" White	A. I. (Red).
Lettuces	Bath Cos	Superb White Cos
"	Early Paris	Dwarf Perfection
Onions	James's	A. I.
"	Veitch's Main Crop	"
"	Lisbon	"
Radishes	Scarlet Turnip	Scarlet Globe.
"	French Breakfast	"
Tomatoes	Early	Earliest of All.
"	Large Red	Perfection.
Turnips	Early White Stone	Early Snowball
"	Altricham	"
Marrows	Green (long)	"
"	White	"

It is considered by a good many people economical to save their own seeds rather than to buy each year, but I doubt this, for the following reasons: That a seedsmen's vegetables are grown entirely to produce seeds and all the necessary properties for producing good plants are stored in such seeds, but in the other case the best are picked for consumption, and when the plant's strength is nearly exhausted it is then allowed to go to seed. Thus it must stand to reason that seeds from exhausted plants cannot possibly produce such fine crops or be so fruitful.

E. H. PORREN.
Bedford Road, South Woodford.

CORRESPONDENCE.

(The Editors are not responsible for the opinions expressed by their correspondents.)

THE STRIPED HELENUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR, "T. J. W." is not the only one who has been taken in by this plant. I had a plant given me four years ago without a name, and when it bloomed I never doubted for a moment but that it was a Rudbeckia, and I have shown it as a Rudbeckia with other perennials. This last year, however, I found out my mistake. The colouring of the flowers varies greatly according to the soil. Here I grow it on a dry bank in poor soil, and the flowers are for the most part dark crimson with a few yellow streaks. In a neighbour's garden, the soil of which is deep and rich, the flowers are of a pale washy yellow with crimson streaks. Of the two the former is the better; but, seeing that the plants in both gardens came from the same stock, the difference is remarkable.

Newton Abbot. B. DICKINSON WEBSTER.

DWARF POINSETTIAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I am obliged to Mr. Hensley for his courteous reply to my remarks on the culture of dwarf Poinsettias (page 107). I have never tried keeping old plants in a house with a north aspect with a view to obtaining late cuttings, but suggested that the plan would be worth a trial. I have seen old plants from which early cuttings had been taken standing in quite cool houses comparatively early in the season, and breaking strongly from the base of the stems. It is gratifying, however, to learn that Mr. Hensley has succeeded in inducing young plants from which the tops were removed to be grown as dwarf plants—to break sufficiently strong to produce fine flower bracts. I have tried the plan over and over again, but my plants after being topped never produced really good bracts. I must confess, however, I did not prune the shoots back to a few eyes, as advised by Mr. Hensley, and, besides, the general culture may have been at fault. The Poinsettia is much hardier than many suppose. Many good growers stand their plants in frames during the summer months, airing them freely, and when living in Essex I used to stand old cut-back plants out of doors in a warm position. They grew vigorously, and were removed under glass at the end of September. The finest batch of Poinsettias I have ever seen were grown at Currow House, Norwich. They were planted out when quite small in a pit in good loamy soil. The pit was freely aired in summer, and the plants assisted with liquid manure. By autumn the stems of the plants were as thick as walking canes, and the foliage large, deep green and leathery. The plants were lifted and potted in September and placed in a close, warm pit till they became established. They retained their leaves, and eventually produced grand flower bracts. I knew one gardener who always grew some old cut-back plants in the Pine stove, potting them into 10 inch pots, and bending the growths down under the roof glass. They often attained the length of 5 feet, producing bracts 15 inches in diameter.

J. CRAWFORD.

THE HARDINESS OF TEA ROSES.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Does not the truth lie, as is usual in the case of somewhat extreme statements, between Mr. Fish and Mr. Grahame? Tea Roses are much hardier than is generally believed, but in occasional winters of extreme cold they may anywhere be killed. In the winter of 1894-95 I lost every plant, in spite of earthing up, and many of them were on their own roots. My garden is on a sunny hillside in North west Hampshire, and there is no lack of the circulation of air, which Mr. Arnott thinks desirable; indeed, my frame-lights and other movables are apt to circulate if not anchored. I write to

recommend a very simple and handy method of protection for Roses and many other plants. We cut a supply of Bracken while it is yet green, though mature; this prevents the leaf crumbling off. Then we tie it in ample, but light bunches to sharp-pointed sticks, generally using the split Hazel of triangular section which are used by the thatchers in our country-side, and go by the name of "spars." These are exceedingly cheap to buy or make, are tough and durable, and their shape prevents their working loose in the ground. If a little store of these of various lengths is made at leisure, they can be used most expeditiously and effectively by simply sticking them in upright or at any angle over or among plants. Heavy rain does not beat them down to a layer, as it often does loose Fern, and the fronds being held in their natural position are more effectual and in no way unsightly.

GEORGE ENGLEHEART.

PRUNING ROSE REINE OLGA DE WURTEMBERG.

[TO THE EDITOR OF "THE GARDEN."]

SIR, How should this Rose be pruned? I planted two on a pergola in March, 1898; they have made vigorous growth, but only produced about four flowers last summer, while Climbing Captain Christy, Aimée Vibert, Cheshunt Hybrid, &c., flowered well. The soil is good. E. M. D.

[This fine semi-double light crimson Rose is a most rampant climber, making annual growths some 7 feet to 8 feet in length. Any of these growths that are not soft and pithy should be retained almost their entire length, merely cutting off just the tips. They will then produce several laterals varying from about 6 inches to 15 inches in length. These laterals if cut back to three or four eyes will blossom freely. As your plants are growing upon a pergola you will have an opportunity to spread the growths out in a palmate manner, and thus facilitate the blooming. Very frequently the laterals do not blossom until the second year, and we are inclined to think that this is the case with your plant, but as it was planted two years ago, you should certainly have a good display this summer. In two or three years' time one or two of the oldest growths should be removed, thus encouraging the production of new wood from the base, which will tend to keep the plant in a healthy condition. We have seen this rapid-growing variety planted in a bed among garden Roses, which was a decided mistake, for, in order to keep it in bounds, it must of necessity be pruned in such a manner as to preclude all possibility of any blossom, but it is in pillar form or, as you have planted it, upon a pergola that its fine qualities are made manifest. Eds.]

ABOUT WILD TULIPS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Will any botanist among our readers who has observed and collected on the spot the wild Tulips that occur in the neighbourhood of Florence kindly name and describe them, and tell me to what degree they show variation in a wild state, and how they are related to their representatives in our gardens? T. R.

PROTECTION OF TEA ROSES.

[TO THE EDITOR OF "THE GARDEN."]

SIR, On page 76 of THE GARDEN, Mr. C. J. Grahame, writing on the subject of "The protection of Tea Roses," says: "We have not had a really cold winter since 1880-81"—a misprint, I presume, for 1890-91. He has apparently forgotten all about the winter of 1894-95, when the frost, whilst perhaps not quite so prolonged, was far more severe; and I fancy that Mr. Benjamin Cant and many other large growers of standard Teas will agree with me when I say that the losses were much greater during that winter than in any other season for which any reliable records are available. In the "Rosarian's Year-Book" for 1896, Mr. Mawley, in his very interesting report on the weather of the previous Rose year, refers to a paper read before the Meteor-

logical Society in April, 1895, which states that "the long continuance of frost, combined with its severity, points to the conclusion that during the past 110 years the winter of 1894-95 has only been exceeded by those of 1794-95 and 1813-14." The said paper further states that, given the imperfection of registering instruments at that time, it is quite possible that the winter of 1894-95 exceeded in severity the two others mentioned. B.

SOCIETIES.

READING GARDENERS MUTUAL.

NOTWITHSTANDING the inclement weather, a large attendance of members was present at the fortnightly meeting on Monday evening last to hear Mr. T. Neve, of Simdsham House Gardens, give a paper on "The Renovation of Fruit Trees, especially Apples." The lecturer dealt with his subject in an exhaustive manner, his remarks on pruning, manuring, watering, &c., being of a very practical character. These were made more interesting by a series of photographs of old fruit trees, which had been renovated, in full bearing. An interesting, and at times animated, discussion followed, in which Messrs. Chamberlain, Powell, Fry, Purkis, Parsons, Blake, Cretchley, Bryant, and Turner took part. A splendid collection of Apples was staged by Mr. R. Chamberlain, the well-known fruit exhibitor, of The Gardens, Crossingham. Although rather late in the season the fruit was in splendid condition, the exhibit including Golden Noble, Lane's Prince Albert, Wellington, Rosemary Russet, Royal Russet, Cox's Orange, Rymer, Gascoigne's Scarlet, the Melon, &c. On the proposition of the chairman, Mr. Fry, a hearty vote of thanks was tendered to Mr. Neve for his excellent paper, and to Mr. Chamberlain for his exhibit. Four new members were elected.

ROYAL HORTICULTURAL SOCIETY.

THE next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, February 27, in the Drill Hall, James Street, Westminster, 1 4 p.m. A lecture on "Some of the Plants Exhibited" will be given at 3 o'clock by the Rev. Prof. G. Henslow, M.A., F.R.S. Intending candidates may obtain all particulars of the examination in horticulture from the Secretary, R.H.S., 117, Victoria Street, Westminster.

NATIONAL HORTICULTURAL SOCIETY OF FRANCE.

FOLLOWING the example of our own Royal Horticultural Society, the National Horticultural Society of France has made a material alteration in the size of its monthly journal. The first number for the new year is now before us, and is indeed an improvement on the old issue in every respect. It contains 104 pages of well-printed matter, the leading article being a historical sketch of the society from its foundation to the present time. The article is illustrated with portraits of the society's presidents, viz., the Vicomte Héricart de Thury, Payen, Duc de Morny, Marshal Vaillant, A. Brongniart, Duc Decazes, Lavallee, Léon Say, Viger. The society's library is also being catalogued. One great feature of the library is the large number of other societies' annals, bulletins, &c., that are received in exchange. It is expected that the new catalogue will be published very shortly. C. H. P.

LINNEAN SOCIETY OF LONDON.

AT the evening meeting on Thursday, March 1, 1900, at 8 p.m., the following papers will be read: "Botanical Nomenclature," by Mr. C. B. Clarke, F.R.S., F.L.S.; "Some Foraminifera of Tithonian Age from the Limestone of Nesseldorf," by Mr. F. Chapman, A.L.S.

CONVENTION OF NOVA SCOTIA FRUIT GROWERS. NOTES ABOUT THE APPLE CROP.

THE 36th annual meeting of the Nova Scotia Fruit Growers' Association was held at Wolforth on January 29, 30, and 31. In his annual address President J. W. Bigelow said in part, "The past two years have been most profitable to the Nova Scotia fruit grower, from the fact that we have had fair crops of superior Apples and have obtained the highest prices in the history of the trade, owing to a scarcity in the world's Apple crop. This year our Apple crop will exceed 400,000 barrels, and as most of those have been sold at from 2 dozs. to 3 dozs. per barrel, the net proceeds may be fairly estimated at over one million dollars. Some idea may be formed of the immense profit of this business the past year from the fact that several growers have accepted or refused from 3000 dozs. to 5000 dozs. for this year's crop of Apples, and many orchards have paid this year 25 per cent. on a valuation of 1000 dozs. per acre. This is owing to the fact that Nova Scotia was the only Apple-producing country that had 90 per cent. of an average crop, the others ranging from 70 per cent. to 20 per cent., and all together averaging less than 50 per cent. The only drawback to this year's fruit harvest was the unusually warm weather during October and November, which prematurely ripened our early winter varieties and caused some of them to open "slack" and soft in foreign markets. I think that under our high cultivation, especially if autumns are warm, our early winter fruit, notably Blenheim, Kings and Ribstons, are maturing earlier each year. The complaint of excessive freight rates charged by subsidised lines to London has engaged our attention for the past ten years, and seems to nearer a favourable solution than at first. After a careful consideration of this subject, I am fully of the opinion that as this trade develops the only profitable means of transport will be by small fruit steamers from Bay of Fundy ports, much the same as Oranges are

exported from the Mediterranean and Bananas from the West Indies. Within the next five or ten years we must provide for an export of over one million barrels annually, and the steamship company which secures this business from Bay of Fundy ports at half the present cost will have one of the most profitable export trades from this continent.

In discussing the question "What varieties of Apples shall we propagate?" Mr. Robert W. Starr advised the testing of new or promising sorts, especially those of European origin, for more than one third of the standard commercial sorts now grown in Nova Scotia originated in Europe. English Apples especially seem better suited to our maritime climate than those which originate in the interior of continents. Admitting that we even now grow too many varieties, this does not mean that we have yet found the best, for all must concede that many of our so-called "standard varieties" have serious faults which lower their value to the grower. If, from testing one hundred varieties of carefully selected new and foreign sorts, we can find one only for the midwinter season that will prove as good as Gravenstein is for the autumn months, then we shall be well paid.

Dr. Wm. Saunders, of Ottawa, Ontario, in speaking of the exceptional quality of Nova Scotia Apples, said that he considered it largely due to climatic influences, for it seemed to be a law of Nature that the further north you can mature a fruit, the finer the quality and the better it will keep under the same conditions. He spoke also of the work that has been done in attempting to produce an Apple which will be hardy in Manitoba and the North-west Territories. Finding that *Pyrus baccata*, a species from Russia with fruit the size of a cherry, was perfectly hardy in the most trying situations, it was thought that by crossing it with our most hardy Apples a hybrid might be produced which would be sufficiently hardy to withstand the climate of Manitoba, and yet of such size and quality as to at least supply the home demand there. This was accordingly done, using pollen from Duchess of Oldenburg, Fameuse and Yellow Transparent. The resulting seedlings have made vigorous trees which fruited in four years, and the fruit was as large as the Siberian Crab, fully ten times the size of the original. Certainly this is encouraging, and one or two more crosses may produce an Apple that will be entirely satisfactory.

The question of the inspection of Apples packed for export was given a large measure of attention. While careless and fraudulent packing is believed to be less prevalent in Nova Scotia than in Ontario, due largely to the fact that the Nova Scotia Apples are for the most part packed and shipped by the growers themselves, yet it is feared that it is increasing, and that some step ought to be taken to check it. The following resolution on the subject passed by the Ontario Fruit Growers Association was discussed at length, and most of its provisions were heartily approved:

Resolved, that both the Dominion and the Provincial Legislatures be asked to consider the advisability of legislation to carry out the following regulations for the sale of Apples and Pears:

1. That all Apples and Pears packed for sale in closed packages shall have the minimum diameter of the fruit inside marked in plain figures on the top or face end of the package, thus, 2 inches, 2½ inches, 2¾ inches, etc., as the case may be.
2. That all such packages shall also be stamped with certain grade marks which shall be defined as follows:
 - (a) X A No. 1. Sound Apples or Pears of uniformly large size and high colour for the variety named, of normal form, at least 90 per cent. free from worm holes, scabs or other defects.
 - (b) X No. 1. Sound Apples or Pears of nearly uniform size and good colour for the variety named, of normal form, at least 90 per cent. free from worm holes, scabs or other defects.
 - (c) No. 1. Sound Apples or Pears of fairly uniform size, at least 80 per cent. free from worm holes, scabs or other defects.
 - (d) No. 2. Apples or Pears that are disqualified from being classed under any of the above mentioned grades, but which are useful for culinary purposes, and not less than 2 inches in diameter.
3. That all Apples and Pears packed in closed packages be subject to inspection by the government inspector.
4. That provision be made for inspection not only at the ocean ports of export, but also, at the request of the shippers, at local points of shipment in the case of ear lots.
5. That for local inspection a reasonable scale of charges be made of the shipper requesting such inspection, gauged according to the number of carloads to be inspected.
6. That in such latter case the inspector shall apply some distinctive inspection brand to show that the packages have been inspected and found to be honestly packed.
7. That the name of both packer and shipper be required to be placed on each package.

The only objection to this resolution was that it was not sufficiently stringent when it allowed of 10 per cent. of defective fruits in the two highest grades, and 20 per cent. in the third. A sufficient number of such specimens will find their way into these grades either intentionally or unintentionally without making direct provision for it. The resolution was therefore amended by striking out these clauses, and was then passed unanimously. E. C. SEARS.

ROYAL GARDENERS ORPHAN FUND.

LORD BATTERSEA has kindly consented to preside at the next festival, which has been fixed to take place on Tuesday, May 8, at the Café Monno, 46, Regent Street, W.

ANNUAL MEETING AND ELECTION.

It is most gratifying to find, at a time when great demands are being made upon the pockets of the people owing to the many war funds, that so much success has attended this excellent charity. This was conclusively shown on the occasion of the twelfth annual meeting at the Essex Hall, Strand, on the 16th inst. It is true the attendance was not large, but those present were all earnest supporters of and workers for the fund, and there was observed a general feeling of satisfaction with the report and balance sheet.

Mr. A. W. G. Weeks presided in the unavoidable absence of Mr. W. Marshall, and it could be gleaned from the report that the committee had been able to increase the amount of the year's aggregate allowances made to the orphans. Since the establishment of the fund 113 children have been placed on it, and the total amount paid on account of orphans during this period is £711 2s. 6d. There were 72 children enjoying the benefits of the fund, which the annual meeting added to by electing 14 others. Amid the satisfaction generally experienced by the supporters to the fund there is the regret that the gardening profession support it only to a very limited extent. An appeal to the large number of professional gardeners up and down the country barely pays the expense incurred in doing so. Were it not for outside assistance the benefits of the fund would have to be seriously curtailed. General donations are almost equal in amount to general subscriptions, and of these latter gardeners supply but a moderate proportion. During the past year the sum of £973 12s. 6d. was paid out on account of orphans.

The officers of the fund were re-elected and additions made to the committee. Mr. N. Sherwood was re-elected treasurer; Mr. William Sherwood was elected a trustee of the fund in the place of Mr. Sydney Courtland, deceased; Mr. B. Wynne was re-elected secretary; Mr. Martin Rowan as auditor; most of the outgoing members of the committee were re-elected and some new blood added. The names of thirteen candidates appeared on the voting papers, from which nine had to be elected. Of these, six were making a third application, two a second, and five a first. The scrutineers—Messrs. Alderson, Bates, R. Dean, Jones, McLeod, and Pompart—reported that the elected candidates were Hilda K. M. Rogers with 506 votes, Aaron Hall 470, Winifred Moxham 429, Charles A. Drantfield 427, John Baird 254, Edward White 237, George W. Stevens 153, Margaret M. Wood 148, and Sarah L. E. Langley 135. The foregoing were declared duly elected to the fund. Mr. R. Dean then proposed that Arthur G. Stephenson and Ernest S. Henderson, unsuccessful candidates, together with the following, whose applications had been received too late: Mary A. Wood, Fred George King, and Joseph G. Riddle, be placed upon the fund by a vote of the annual meeting, as the state of the funds justified that action, especially as some of the children chargeable to the fund would cease during the coming year to be a further charge upon it by reason of the action of the age limit. This was seconded and carried unanimously, and in this agreeable manner the proceedings came to a close.

GRAND YORKSHIRE GALA.

THE northern floral and horticultural *fete* will take place on the 13th, 14th, and 15th of June, 1900, in Bootham Field, York. The prizes, in all amounting to £750, are as follows: £300 for Orchids and greenhouse plants; £200 for Pelargoniums, Carnations, Begonias, &c.; £100 for Roses, cut flowers, &c.; and £90 for fruits and vegetables. Special attention is directed to classes 20 and 20 for pot Roses, for which large prizes are offered. The first prize for a table of Orchids is £12, the others being £10, £7, and £4. There are four prizes for a table of fruits arranged for effect, the first award amounting to £15. High-class floral designs and effective arrangements are also encouraged. There are no less than 100 classes. Schedules can be obtained from the secretary, Mr. Charles W. Simmons, The York Hotel, York.

KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.

THE annual general meeting of the subscribers to this society took place recently, the chair being taken by Mr. W. Drewett. The report shows a balance in hand of £1 14s. 9d. To that has since been added two other sums, increasing the balance to £3 3s. 8d., and hopes are entertained that a little more will be recovered. We are pleased to know that the society has no debt, and the committee earnestly appeal for funds to make the coming twenty-fourth exhibition a success.

The report and balance-sheet was unanimously adopted, and hearty thanks given to Mr. W. Drewett, who as chairman of the committee had assisted greatly in making the society financially secure. Sir J. Whittaker Ellis, High Sheriff of Surrey, was re-elected to the office of president. Mr. A. W. Homershaw was re-elected treasurer. Mr. William Hayward, florist, Fife Road, was unanimously elected to the office of secretary, a position he will doubtless fill with ability and satisfaction. The election of twenty members of the committee was then proceeded with, and as twenty-three persons were nominated the voting was by ballot paper. On counting these it was found that Messrs. W. Drewett, W. J. Wells, A. Dean, Randall, Hawkes, Pitcher, Neave, Cusson, Blencone, Smart, Lane, Atkins, Dorsett, Holt, Jenkins, Gibbons, Watts, Bilton, McCormack, and Pead were elected. Of this number twelve are gardeners, representing Hampton Court, Tollydown, Kingston, Thames Ditton, Esher, Surbiton, Combe, and Kingston Hill. At a meeting of the committee held later Mr. W. Drewett and Mr. W. E. Wells were re-elected to the posts of chairman and vice-chairman. A meeting was held on the 16th inst. to consider the drafting of the schedule for the current year.

RURAL ELEMENTARY EDUCATION.

At the council meeting of the Royal Agricultural Society of England on Wednesday, February 7, presided over by His Royal Highness the Prince of Wales, the subject of rural elementary education was brought up by Mr. Martin J. Sutton. Mr. Sutton desired to ask Lord Moreton what steps the Education Committee were taking to fall into line with the present feeling in the country on the

subject of the education of the rural population. He was a member of a deputation recently received by the Duke of Devonshire, who assured them that measures in this direction would shortly be taken by the Education Department. But His Grace made it quite clear that, if anything effective was to be done, the department would require adequate support out of doors. This was a work which might very appropriately be undertaken by that society, which ten years ago had given to the world a most valuable text-book on agriculture, which still held the field. This book was, no doubt, too advanced for the children attending elementary schools in rural districts, but he put it to the education committee whether it would not be possible for them to prepare and publish simple reading books on subjects relating to agriculture, such as the different breeds of stock, farm implements, natural science, and the like. He thought that by interesting, and at the same time educating, country children in the farm life around them, something would be done to check the stream of migration from rural districts to large towns, which every year made it increasingly difficult for farmers to gather in their harvest, owing to scarcity of labour. Lord Moreton thought that council would agree that in the past the education committee had not been behindhand in doing what they could for agricultural education, and one of their most useful acts had undoubtedly been the publication of the text-book referred to by Mr. Sutton. The present demand appeared to be for agricultural education in elementary rural schools, and he undertook, on behalf of the education committee, that they would go thoroughly into the whole question raised by Mr. Sutton.

ANSWERS TO CORRESPONDENTS.

Names of fruit. B. J. 1, Lady Heniker; 2, Waltham Abbey Seedling; 3, Red Streak; 4, Lemon Pippin; 5, Warner's King.

KITCHEN GARDEN.

Seakale (H. E.). If you have no old Seakale roots which you can lift, and cut from them the side roots to make cuttings, or you cannot purchase root cuttings, then your best course will be to purchase 1 lb. of seed, for it is very light, and sow it. But that must not be done until the first week in April. In the meantime get a piece of ground, say a couple of rods in extent, trenched or deeply dug, working into it a good dressing of manure, so that it will settle down, and will be ready to sow the seeds in at the time named. The drills, drawn as for Peas, should be about 20 inches apart. Sow the seed thinly, so that when the young plants are up they can be thinned out to 9 inches apart. During the summer use the hoe freely, and in July hoe in a light dressing of salt. By the middle of November next you should have plenty of strong root fit to lift to force or blanch, and after you have cut from them all the side roots for making root cuttings, to plant out instead of sowing seed.

Mustard and Cress (HART). Whilst gardeners generally sow true Mustard seed with Cress for small salad, the market growers use Rape seed, as that is cheaper and the growth is much milder. Probably in private use Rape would be quite as acceptable as Mustard. It is less hot, that is all the difference. But the market growers practically exclude light from their crops, whilst private growers seldom do so. We have seen large frames in which the seed has been, after having been soaked for a few hours, spread all over the surface, gently watered, then covered with bast mats. As the growth proceeded the mats were bodily lifted, and in about six days removed, the Rape and Cress being quite ready to cut. Where seed is sown in pans or shallow boxes and stood in warm frames or houses, it should be covered up in the same way with paper, as quick blanched growth results, and that is tender and pleasant eating; it also helps to keep the salad clean. A stock of soil should be at hand for the boxes, quite one-half being manure, and sowings should be made very often at a constant supply is desired.

Early Potatoes (CELE). First early Potatoes are numerous, and differ comparatively little in respect of earliness to produce tubers, in productiveness or in table quality. A good stock of the Ashleaf Kidney, King Edward, Duke of York, Loates's Short-top, Harbinger, and Sharp's variety are all quite first early and of the best. These varieties all do well grown in 8-inch pots in a house or frame, or planted about 12 inches apart in well-manured soil on a warm border. If you can grow any under glass, then get tubers and plant out pot at once if you wish. But we should prefer to set the tubers on and close together in shallow boxes, to stand them in a warm house in the light to cause the eyes to sprout. Then to reduce these on each tuber to two at least before planting. Those to be planted outdoors will be best in the boxes until the first week in April. Nothing is gained by planting too early. In the meantime the tubers will be making better growth in the boxes in full light,

Outdoor Tomatoes (ANXIOUS). Nothing is to be gained by sowing seeds of Tomato for outdoor culture later too early. The plants would but become drawn and weak. Better to sow seed early in April, either in gentle heat or without. The plants should be strong enough to lift from the seed pots or pans by the end of the month to get singly into 3-inch pots, and then be kept on shelves near the glass or in a frame close to the light. In a couple of weeks shift the plants into 5-inch pots, still keeping them well exposed to light and air, as it is important they should be stout and well foliated. Gradually harden the plants off by ample day exposure towards the end of May, and then they will be about 10 inches in height to plant out early in June, when it is fairly safe to do so. Use for pot compost chiefly loam with a little old hotbed manure and some sand. Let the garden ground be deeply dug, but not freshly manured as the plants grow; rather mulch them with long manure.

INDOOR GARDEN.

Pyramidal Fuchsias (J. W.). Without doubt the pyramidal form of growth is natural to the Fuchsia generally, although some varieties have a spreading tendency. If you can take from such plants as you have nice young shoots 3 inches in length, and set them as cuttings into pots filled with sandy soil and well drained, then stand them in good warmth, they will soon become rooted and make rapid growth. Shift them into 3-inch pots, grow them on in gentle warmth and ample light, putting small sticks to support each plant. As soon as flower buds break from the leaf joints, at once pinch below these and compel new shoots to be formed. Shift the plants on into larger pots and keep them under glass. Another pinching will be needed, but each pinching will leave the plants 6 inches higher, until by the autumn they may be in 9-inch pots, and each one from 4 feet to 5 feet in height. Treat the same the following year, and you will get them over 6 feet in height, forming noble specimens. We have seen splendid plants fully 8 feet in height when in full bloom very beautiful objects.

FLOWER GARDEN.

Trimming Ivy (CHARLTON). Certainly there is no better time for hard trimming of Ivy on walls or fences than about the middle of March. In your case the climber having suffered from wind and snow and become somewhat ragged in appearance, it is best to cut quite hard in. That may be done with stout sharp shears or with a knife, but however done it is evident that the effect will be for a short time undoubtedly objectionable. But then by doing this hard cutting in March this objectionable feature is greatly minimised, as very soon new growth begins, and in a few weeks the surface is pleasantly green with young leafage. When Ivy is grown on tree stems or poles, or where forming pillars or covering arbours, &c., then the pruning should be done with a knife, so as to leave the bulk of the leafage unimpaired. Ivies as a rule bear hard pruning well, but still it is work that should be done judiciously, especially with variegated forms.

Hardy Fuchsias (TYRO). Few Fuchsias are really hardy, but in the south, and particularly in the Isle of Wight, such varieties as Riccartonii, globosa, corallina, and others seem to exist as ordinary bushes, but generally these varieties, as also Rose of Castile, excelsiensis, magellanica, gracilis, and others, have to be cut hard down in the autumn and the roots protected by heaps of leaves or ashes; then in the spring they break up freely and form most handsome bushes. No doubt where the soil is fairly porous, an occasional dressing of decayed vegetable matter or old hotbed manure is given, and the situation is a warm one, many of the ordinary greenhouse varieties would do as well. Subject to similar treatment, Fuchsias grown in large pots as half standards, that is, on about 3-foot stems, plunged in grass during the summer, make beautiful garden objects. Most varieties of Fuchsias are more largely used for summer bedding.

Early-flowering Chrysanthemums for the outdoor border (J. R. H.). By confining the selection to SIX, or possibly a dozen, sorts, these embracing some of the best pompons as well as the leading Japanese varieties, there should be little difficulty in brightening the garden in the early autumn. Those most suitable for this work are: Alice Butler, bright red suffused with orange, height 2½ feet, flowering latter part of September and later; Camari, lemon-yellow, very bushy and compact, height 1½ feet, period of flowering same as last-mentioned variety; Little Bob (syn.), Scarlet Gem, crimson-brown, fairly bushy habit, height 2 feet, in flower latter part of August and September, a splendid bedding sort; Mr. Selly, rosy pink, bushy and compact, height 1½ feet, an ideal plant for the border, flowering same as last named; and Mme. Jolivart, white-shaded pink, very bushy and free flowering height 1½ feet, flowering throughout September. Japanese are best represented by Mme. Marie Masse, lilac-mauve, and a chestnut-bronze sport from this variety named Crispin Marie Masse. They are both beautifully branching in their style of growth, also free-flowering, and possess a good constitution, height 2 feet, flowering throughout September. Comtesse Foucher de Cariel, bright orange, bushy, free-flowering, height 2 feet, period of flowering mid-October, one of the best; Ivy Stark, pale orange-yellow, bushy habit, good constitution, height 2½ feet; Noture Croz, nutmeg-pink, very free in growth and in its blossoming, should not be disbanded, height 4 feet, in flower first week in October; and Myelnet White, pure white, bushy habit, and free-flowering, height 1½ feet, flowers throughout September.

Tufted Pansies, half-a-dozen good bedding sorts (W. S.). You will be surprised to learn that the sorts mentioned in your interesting letter have long since been superseded by varieties distinctly ahead of them in point of colour, freedom of bloom, and habit. During recent years many charming kinds have been raised developing a perfect habit of growth. Unlike the old flowers with dark rays running into the eye, these newer sorts are absolutely rayless,

and many of them are fragrant. Those of a straggling, weedy growth are becoming fewer, and this is something to be thankful for. With the newer introductions, partaking as they do of a true tufted and compact style of growth, it is possible to have grand masses in our beds and borders carrying the most delicate blossoms of the most refined and chaste character on a groundwork or carpeting of rich green foliage. Commencing to blossom in the spring, the plants may be kept in good condition right through until autumn, provided they are treated generously and the spent blossoms are removed from time to time. The best six sorts are: Devonshire Cream, as its name implies, is a beautiful pale cream-coloured flower and rayless, and is also very free and tufted in growth; Pembroke, rich canary yellow, very free, not quite so compact as most others, but indispensable; Virginius, the very palest shade of bluish-lilac, almost white, splendid habit, and very free; Concessior W. Waters, a new shade of crimson-purple, free and compact, wonderful constitution; Kitty Hay, one of the most effective rich rayless yellows for bedding in existence and little known, good habit; and Florizel, a new shade, bluish-lavender, a most effective flower, rayless. Small pieces will ultimately develop into grand clumps. This selection is much too limited regarding varieties. You should increase the number of sorts.

Chrysanthemums of a crimson colour (P. W.). It is not long since Japanese Chrysanthemums of a crimson colour were very few, Jeanne Delaux at once being the most popular variety for exhibition as well as conservatory decoration. You will find the following varieties answer your purpose admirably, though to see some of them at their best the plants must be grown on strongly and second crown buds retained. First crown buds of most of them give rough flowers of indifferent colour, these also showing the reverse side of the petals. The selection of second crown buds should obviate all this, and provide neat refined flowers of good colour. Joseph Chamberlain, rich velvety crimson, bronze reverse, long drooping florets; S. W. Gilbert, deep rich chestnut-crimson; Edwin Molyneux, bright crimson, golden reverse; G. W. Childs, deep brilliant crimson, good for late displays; John Shrimpton, rich velvety crimson, a capital bush plant; Master H. Tucker, crimson-chestnut, bronze reverse, handsome flower; Matthew Hodgson, crimson-red, a grand plant, invaluable for rather late work; Nyanza, chestnut-bronze; Eastman Bell, bright crimson, of easy culture, resembling Edwin Molyneux; Royal Standard, rather dull purplish crimson; William Seward, deep rich crimson; Lionel Humphrey, rich chestnut, golden reverse, new; Helen Shrimpton, crimson, shaded rose, new; H. J. Jones, deep rich glowing crimson, a very striking flower, new; Lord Cromer, very bright crimson, rich golden reverse, new; Henry Weeks, rosy crimson, flushed carmine, of easy culture, new; Reginald Godfrey, light chestnut-red, shaded copper, with golden reverse; Sir Herbert Kitchener, bright golden chestnut, bronze, and amber, effective colour; and Richard Dean, deep chestnut-crimson, gold reverse, late buds only in this case. Others might be added, but for your purpose this selection should make a good display.

TREES AND SHRUBS.

Flowering shrubs (G. G.). Planting these charming hardy shrubs may be continued till the end of March, but they are best planted in the autumn. You will find a couple of the Daphne Mezereum, red and white, a couple of the beautiful yellow-flowered Forsythias, a couple of the red and white-flowered Cydonias, the same of the Flowering Currants, Ribes, Dentzia gracilis and crenata, Berberis buxifolia and Darwinia, Mahonia aquifolia, Cytisus (or Broom) albus, Scoparium, and C. Andreaus, Medysarum multijugum, with its pretty reddish pea flowers, Magnolia conspicua and stellata, Philadelphus (Mock Orange) grandiflorus and Lemcoinei, the Snowballs, Viburnum Opulus and plicatum, Spiræa in variety, Lilacs, double and single, Rose Acacia, and several varieties of Hibiscus to constitute a lovely selection of flowering shrubs that do well in ordinary soils, although there are many others that could be included did space admit.

MISCELLANEOUS.

The last cold winter (R. F. G. O.).—The last great frost occurred in January and February, 1895, and lasted for nine weeks, beginning at the end of December, 1894, and coming to an end on March 5. Nowhere was the effect of this frost so evident at a glance as on the commons, where throughout the length and breadth of the land all the Gorse, with the exception of a green shoot here and there, had been to all appearance killed. In most localities, however, a good many of the stems were afterwards discovered still alive, although all the spines on them had been destroyed. — E. M.

TRADE NOTE.

MESSRS. CARTER'S CHINESE PRIMULAS.

MESSRS. CARTER write that their Chinese Primulas are now in full beauty at their nurseries at Forest Hill. We shall have something to say about this beautiful strain next week.

[MARCH 3, 1900.

FLOWER SHOWS AND THEIR INFLUENCE ON HORTICULTURE.

ROSE SHOWS.

WE desire to approach this subject in the most carefully thoughtful spirit, and it appears to us that the best way to arrive at conclusions useful to our readers will be to consider the aims and to observe the judgments of some of the most representative of the great annual shows. Of these the one that naturally comes foremost is that of the National Rose Society.

And we have to consider, at one glance as it were, the Roses and the rosarians, the queen of flowers, and all those of her assiduous cultivators, old and young, veterans and neophytes, who give ungrudgingly of their time, thought, money, and money's worth in their endeavour to do her honour.

Looking broadly at the whole question of florists and florists' flowers, we cannot but be struck by the very diverse treatment given to different flowers by their special cultivators. We hold that the best and truest object of the florist should be to develop the utmost beauty of which the special flower that is taken in hand is capable. And we see that in the case of the Rose this object is most faithfully followed, and at our premier Rose shows especially we see brought together the most perfect blooms of the most beautiful Roses. And though the teaching of the shows, taking one kind of show with another, of all that are known as florists' flowers is not by any means always the most practical teaching for the garden, yet when for instance year after year we see the same good Rose holding its own, we may well be assured that that is a good and trusty kind, and so we have distinctly learnt something.

Whether it is that in the cases of the veteran Rose judges it is because the men themselves are of a high order of refined and cultured intellect and as well as of sturdy and sober judgment, it would be invidious to attempt to say; but it would appear to be so, for in the case of the show Rose there is nothing false or unseemly in the development achieved. It is all for perfect beauty, and thus it is a lesson of right aim that the special cultivators of other of the so-called florists' flowers might well take to heart.

It is obvious that the chief objects of interest

at a Rose show should be the splendid flowers of the Hybrid Perpetual and Tea classes that have so long enjoyed the close attention of both English and foreign raisers, but it is pleasant to see that there is also a wide-minded recognition of the ever-growing interest in the best of the so-called garden Roses; and with a liberality of mind that cannot be too highly appreciated, the National Society is now seeking to widen its good influence in other ways equally helpful to our gardens.

We desire to point out for the thoughtful consideration of our readers a matter that strikes us as of great importance, namely, that those horticultural societies devoted to the culture and improvement of one flower or class of flower, whose shows, by their teaching and influence, bear helpfully upon gardens and do not stop short at the show table, are those that are doing the best and most righteous work; and we see with true pleasure that the National Rose Society seeks to encourage the improvement of many of those humbler, but in their own way scarcely less beautiful, Roses whose presence in our gardens has so direct a bearing on so much of simple and blameless human happiness.

And when we see what improvements are rapidly taking place in one class of Roses alone, and those, perhaps, the hardest of all, namely, the rugosas, we recognise how great an opportunity is in the hands of all such well-constituted organisations as the best of the Rose societies to encourage the efforts of raisers in this and other such worthy directions.

TOO MANY KINDS OF APPLES.

Wise words are written by Mr. Parker upon page 157 about the future of Apple growing in this country. Profitable fruit culture is an industry of the British Isles, but suffers from the inroads of foreign competition and our own peculiar apathy. The markets in winter are stocked with ruddy-cheeked Apples from over the seas, more brilliant in complexion than home productions, without, however, possessing generally the all-precious quality of flavour. The national palate surely needs educating to a better understanding of flavour. Apples with pretty looks, but as wholesome as a bag of sawdust, cover many rich acres in the various counties. This is unfortunate.

Our correspondent rightly points out the folly of growing so much fruit that ripens within a limited period, the effect of which is naturally to leave other seasons of the year, as important as October or November, without a nutritious and much-prized food. The worship, too, of size, as if bigness signified flavour, is

fatal. Size is not the only virtue treasured in an Apple or any other fruit; it may appeal to those unable to discriminate between bulk and exquisite quality and to growers for market anxious to satisfy an ever-increasing demand.

Orchards and gardens are overstocked with kinds of slight value; the grower seems loth to part with trees that spell absolute loss, and then sums up the whole business as profitless—an ill-considered judgment, the outcome of ignorant methods of cultivation passed on from generation to generation.

A hundred varieties are catalogued in books and treatises upon fruit cultivation in the British Isles; the chaff must be sifted from the wheat, and we hope our readers will support our efforts to effect this desirable consummation.

Much satisfactory work in the right way has been accomplished of late years, and the training up of young men in fruit culture will in the end achieve this object. Mr. Parker mentions late Apples rarely heard of, and in many districts good local kinds exist which fruit growers in other counties may find acceptable.

In studying fruit culture the question of soil is all-important. A variety that rarely fails in one soil may do so in another, and this matter applies also to stocks, pruning, and other essential details of cultivation.

The cry of "too many varieties" has been long heard in the land, and many regard the theme as worn threadbare through constant discussion. Whilst, however, facts remain uncorrected, it is necessary to pursue the subject with persistence, taking no heed of sensational descriptions of the possibilities of fruit culture. It is an industry that must be undertaken by men equipped with a knowledge of the work, and a great step forward towards profitable culture will be the reduction of an unnecessarily long list of varieties.

In our next issue we shall give a list of the best Apples, to which other varieties may be added by readers with practical experience.

SOME OF THE RARER SHRUBS AND CLIMBERS.

As you ask me for a list of names followed by a few words of description of some of the best flowering shrubs and climbing plants which I have in this garden, I will try to comply with your request. Tastes differ, so that what one person would put among the best, another would exclude from their number, but not much fault, I think, can be found with the following selection:—

Edwardsia grandiflora.—There is no difficulty about this beautiful shrub at all. In the Isle of Wight it blossoms with great regularity every year, and it is always admired. I think it comes from New Zealand, and it used to be called *Sophora tetraptera* because of the four wings which the seed-vessels have. How the name came to be altered I do not know. There are few more attractive sights in the month of

April than a large specimen of *Edwardsia grandiflora* if it is grown against a wall with a western exposure, and therefore is blossoming freely. The whole tree is thickly covered with pendulous bloom branches of yellow, and though it cannot exactly be said that they are of a golden colour, they come so near to it that no great distinction need be made. I do not find it at all tender in this part of the world, and I never think of protecting it in the hardest frosts we have. It is propagated in the easiest manner either by seed or by cuttings. Mine was obtained from seed, which I gathered a long time ago from a tree which has been grown for years and years against the south wall of St. Clare Castle in this parish. I soon had many more specimens than I knew what to do with, and some three or four of them have attained a great height against the walls of St. John's Church, or in my garden.

In near proximity to *Edwardsia grandiflora* is *Poinciana Gilliesii*, which I may safely assert to be the greatest success I have ever had in this place. One mourns over disappointments from time to time, and a run of them—which occasionally occurs—is against enthusiasm for a little while; but I think it should never be forgotten that our losses are balanced by our gains, and one great gain almost unexpected, and largely in advance of what had been imagined at all atones for a great deal of ill-success. Such to me has *Poinciana Gilliesii* been from the beginning, and such it looks as though it would continue to be. The origin of its being in my hands at all was a very casual one. A long time ago—considerably more than twenty years at least—I was talking to Canon Ellacombe about things in general, and plants in particular, and he happened to say to me, "I should not be surprised if *Poinciana Gilliesii* were to succeed in the Isle of Wight." I made a note of it at the time, and determined to try it as soon as I could get hold of the plant, but here was the great difficulty in the affair. It was not to be heard of at any nursery in the kingdom, and I did not then know so much about the Italian nurseries as I have come to know since. I was driven, therefore, to try and grow it from seed, and, luckily, Mr. Thompson, of Ipswich, was able to supply me with a packet of seed, which just gave me the chance I desired to have. It was the best investment of 4d. which I ever made in my life. Like most leguminous plants, it gave no trouble at all, and I soon had quite a crop of young seedlings, which was just what I required. I gave away some of them, and lost others through inevitable neglect, but I planted two or three in the open border to see if they would do in this way. Their success has been beyond all expectation, and no one ever sees them in the autumn but says it is quite one of the finest flowering shrubs we possess.

Poinciana Gilliesii—or, as it is otherwise called, *Cesalpinia Gilliesii*—comes from South America, and is abundant on the margins of rivers and in irrigated grounds about Mendoza. The foliage gives it very much the look of an *Acacia* at a little distance, and it is often mistaken for one of them. But no *Acacia* that I have ever seen has such splendid blossoms as this shrub has. The flowers are large and sulphur-coloured, in a terminal corymbose raceme; the stamens are ten in number, of which the filaments are bright red; the anthers are also red, and the style is rather larger than the stamens, and of about the same thickness and colour. Altogether the blossom has a most imposing appearance, and when it is understood that the foliage is also attractive in the highest

degree, there is not much left to be desired. My great surprise has been in the well-doing of *Poinciana Gilliesii* to such an extent in the open ground I have now no fear for it at all, and during the worst frost we have had here during the last twenty or thirty years it was entirely uninjured. A very great recommendation for it in my eyes is the time of year when it is accustomed to blossom. All spring things have gone by, and the wealth of flowering shrubs and trees has become exhausted when this very beautiful object rivets attention and makes full compensation for any loss that has been sustained. Moreover, it goes on for such a very long time—blossoming, it is true, in an intermittent sort of way—but still remaining an attraction in the highest degree in the garden for week after week. It is, I think, rather exhausting to the border in which it is placed, and for a year or two after it had become established it seemed to hang fire, if I may so say, for want of sufficient sustenance for its needs; but this was soon rectified, and now we give it every year a few barrowfuls of very good stuff, and the difference is immense in the crop of blossoms which follows. I am afraid it will not succeed everywhere as it does in the Isle of Wight; but *Poinciana Gilliesii* is so excessively handsome, that it should be tried wherever it is likely to have a chance. In Cornwall and Devon I should say it would be quite certain to prosper.

Mandevilla saxeolens is very well known, but more as a greenhouse climber than anything else. It comes from Buenos Ayres, and its pure white, trumpet-shaped blossoms which are highly fragrant are extremely desirable. As a greenhouse climber, however, it is liable to one very strong objection—it becomes infested with red spider, and, unless it is constantly syringed, it becomes almost a nuisance to other things. So at any rate I found it to be. It grew at a very great rate and took up a good deal of space, and when it became so difficult to keep clean I almost got tired of it. My gardener and I put our heads together and we determined to let it take its chance in the open; if it had to die it must do so, but if it could live and do well in the open air, it would be a clear gain from every point of view. We chose out the warmest corner we had at our disposal, and in the month of April *Mandevilla saxeolens* had to find a new home. To my immense satisfaction it prospered a great deal more than it had ever done before; that is to say, it grew immensely, blossomed profusely, and was very soon rid of red spider and other abominations to which it had been exposed. In the open border it may safely be said that in the Isle of Wight and other similar places there is not a single objection which can be made to it; on the contrary, it becomes an object of the highest admiration, and the abundance of my pure white flowers, which are produced in July, is truly surprising. I should perhaps say here that once only since its exposure, some twelve or fifteen years ago, has it got into trouble. In that very hard frost of the winter, I think, of 1881 *Mandevilla saxeolens* was cut down to the ground. I mourned over it as dead for some weeks, and was most agreeably surprised in the early summer to find that it was shooting out from below and beginning to grow vigorously. So vigorously did it grow, that it touched the roof of my house before the season was over, and though it did not blossom that year, it had the promise of great things about it, which has since been fulfilled. It is as strong now as ever it was, and as the stems are bound round during winter with bracken and straw, I think it is proof against injury. I

may almost engage to say that in the coming July this splendid climber will be a sight to see. So refreshing is it in very hot weather, that it arrests every passer-by, who at once is sure to exclaim, "It is one of the most beautiful things that I ever saw in my life."

Mandevilla saxeolens has found its way to Jersey and Guernsey, where it is plentiful enough, but there must be many other places which it would like very well where it is not as yet to be seen.

H. EWBANK.

St. John's, Ryde, Isle of Wight.

(To be continued.)

DEEP CULTIVATION.

As I anticipated, a somewhat lengthy and, I hope, beneficial discussion has followed my notes, and I trust, with the permission of the editors, others interested will see their way to give their experience. There is, of course, always two sides to a question. I am only anxious to impart to the many readers of your valuable paper what each of us believe to be the way of producing the greatest bulk of high-class vegetables on a given space. So far, the arguments for and against, I think, are pretty evenly divided. I will endeavour to the best of my ability to answer those which differ as briefly as possible.

Firstly, an "Old Hand" on p. 88. I am much obliged to him for the compliment he pays me on the quality of vegetables I have exhibited from time to time. Then he says he is sorry to differ from me on the treatment of clayey land. He says: "In every garden circumstances differ." Exactly; but the system remains the same. As I have before stated, I have had experience with chalk, gravel, and clay, and on each occasion I have adopted the same course, and with the best results. I know only too well what deficiency of labour means, and I fully sympathise with those placed in the same position.

Then, again, manure. I am aware in some cases there is much trouble in obtaining sufficient, but in all gardens there is a large amount of waste and refuse, sweepings of walks, &c., which can and should be liberally worked in, and I am perfectly convinced there is much more fertility in what many call inert clay than is generally supposed when opened up, brought to the surface, and exposed to the influence of the weather. Your correspondent also states that some soils are so poor at 3 feet, that it will take years to make them good, but my contention is that the poorer the soil the more reason there is for fetching it up and making what should be a good depth of workable soil in the kitchen garden, which has to be cropped and doubly cropped in many instances annually. I assure "Old Hand" that if I were placed in his position with only a foot or 15 inches of soil on a sandy gravel subsoil, I should endeavour to set about quickly and produce a better depth by the means I have set forth. Too many people imagine that after once the ground is trenched it is done with; but surely not so. Every season, if not the whole of the garden, as much of it as possible should be trenched or bastard trenched. Then, and then only, in my opinion, can the best results be obtained.

After carefully reading the comments of the Rev. G. Engleheart, I certainly think he travels very wide of the mark. My notes were intended purely for the kitchen garden, but I observe he feels justified in mixing up the farm, fruit garden, herbaceous border, and pot plants, and he brings forth science to bear out his argument, none of which I object to. He thinks the gardener will do well to take lessons from the scientific farmer. Perhaps in a few cases he may, but my opinion generally is just the opposite. I think the present-day farmer would do well to take a few lessons from the gardener.

Mr. Engleheart mentions the Raspberry, for instance, in support of his argument. Now everyone is aware that the Raspberry is a surface-rooting plant, but, assuming it is planted on a deeply cultivated piece of land, there is nothing to

prevent the roots from remaining on the surface, and the same applies to all other surface-rooting plants. I made my plantations of Raspberries on trenched ground with good results, but annually give them a surface-dressing of manure. When the time comes round to make a fresh plantation the quarter is again trenched, and the consequence is the first bottom spit is again brought to the surface. Then surely we have a better depth of good workable soil than would otherwise have been the case and fit to receive almost any kind of crop one cares to try. He then goes on to say: "Even the very school-children can now tell us how the rocks by the influence of the weather, &c., have been converted into the top spit of soil." Quite true; and this substantiates my argument. Take, for instance, chalk which is perhaps buried only a few inches under the soil. Bring it to the surface in the autumn, and what do we observe in the spring after being subjected to the influence of the winter's weather? Why, the first winter will pulverise and slacken a great portion; whereas, if kept beneath the sur-

face I determined to set about trying what could be done to improve matters, following my own ideas. I commenced one end by opening out a trench 3 feet in depth and the same in width, and I converted this into the rubbish yard, in which we buried any kind of rubbish generally to be found in the garden, including short grass from the lawns. As this became full up I opened out a fresh trench with which I covered the rubbish, and the beneficial results have so far exceeded expectations. Those first treated have grown and developed well. I have cropped between the trees with vegetables each year with the best results, but it is intended to lay down the whole with grass eventually. I cannot think that the argument respecting forest trees finding out tempting heaps of soil placed near them has much to do with deep tillage of the soil. I am sure that if a piece of ground is deeply cultivated and enriched near most of our forest trees they would find it out and revel quite as much in this, and with more beneficial and lasting results than if allowed to rise up unaturally many feet possibly above the

piece of ground in question, which had been, as he stated, trenched for the first time to a depth of 3 feet, and on which I had grown one of the best crops of Potatoes it has been my pleasure to lift since I have been at Allenham (nearly sixteen years). The ground was trenched during winter and left rough till planting time. Small trenches were taken out with the spade and a small quantity of leaf-soil placed in, on which the sets were planted. Over these a layer of the subsoil was placed, and I allowed a distance of 3 feet from row to row. Between these I grew a crop of Savoys. Nothing in the way of fresh material was given these, and I assure Mr. Hall a better piece of Savoys I have never grown. On the same strip of land I also had Lettuce, Turnips, Artichokes, and Carrots. Holes were bored for the latter, which were filled up with a fine compost; the rest were grown simply in the clay, except a little fine soil sown in the drills with the Turnip seed, and nothing could possibly have done better. I cannot see what draining has to do with land cultivated at a depth of from 2 feet 6 inches to 3 feet any more than it does at a less depth. I should say no one will dispute the absolute necessity of draining land under cultivation as a kitchen garden, especially so if wet and retentive.

I am distinctly at variance with Mr. Hall as to his treatment of clay soil. I, too, know something about the burning of this material—by no means a new invention—but never again will I advise or practise such a method. I consider burnt ballast the worst material one can introduce into a kitchen garden for the production of high-class vegetables. London clay, I am quite aware, is very different to a strong loam. Mr. Hall seems to lose sight of the fact that I do not propose to bury away the topsoil for ever. A practical gardener will always know where to find it when the trenching is again repeated, an operation which should be often carried out. My desire is to obtain a good depth of workable soil rather than a foot or 18 inches, and which I repeat can be done if carried out as I advise. Most of the vegetables I have exhibited have been cultivated on land as described by me, but no doubt he is also aware that for Carrots, Beet-root, and Parsnips I have to resort to boring holes and fill up with a suitable compost to produce my best specimens, even these are grown on the

E. BECKETT.

Abraham House Gardens, Elstree, Herts.

CLEMATIS PANICULATA.

It happens not infrequently that some good plant that might be of the utmost use in our gardens is in some mysterious way overlooked and is virtually unknown. Why so good a thing as this excellent Clematis has so long suffered this most undeserved neglect it is impossible to say; but though it is well known in botanical collections, and though it figures in the list of one of our best seedsmen, it is very rarely to be seen in gardens. Clematis paniculata will do for us in the shortening days of October what Clematis Flammula does in September. It does even more, for though it has not the delicate, almost nebulous, lightness of mass of C. Flammula, its masses of bloom are borne even more abundantly. The two plants have so much in common, that one may, for

CLEMATIS PANICULATA IN A BASKET.

face, it will for ever remain in the same condition, and we have only to notice our railway cuttings, &c., in support of this, and the same thing applies to clayey and other soils. Even for the flower garden or herbaceous borders I should advise deep preparation of the ground, but not to the same extent as in the kitchen garden. Now, as to fruit trees, does Mr. Engleheart mean to say to trench 2 feet or 3 feet for an orchard is a mistake? I do not wish to be misunderstood. I certainly do not, and never did, advocate deep planting. I know only too well that far too many fruit trees are planted at too great a depth, especially when holes are merely dug out and the trees planted therein. I will quote an instance. About twenty-five years ago a new orchard was planted, half of which was deeply trenched and the remaining half planted by simply digging out the holes. Now the difference was apparent. Those on the trenched part did well in every respect, making good growth and bearing freely, while the other half proved a complete failure, the trees being only about half the size of the others, and never once has anything like a crop of fruit been produced. Three years

surface. Then, again, Mr. Engleheart quotes the Narcissus. In dealing with this his favourite plant few can question his ability. He states that occasionally, when these have been buried with ashes too deeply, the young roots find their way to the top. Precisely; but I never advise planting or burying anything unaturally deep rather on the contrary. If anyone will turn out almost any kind of plant from a pot, the principal roots will be found near the bottom. Why are extra deep pots generally advised for many bulbs, Hyacinths especially? Why do many of our leading nurserymen go to the expense of deep trenching if shallow cultivation would answer the purpose? Not merely for the employment of labour, but because they are fully alive to the fact that there is hidden treasure below.

Mr. J. R. Hall on p. 129 questions Mr. D. B. Crane's remarks respecting a crop of Potatoes taken from deeply trenched ground here last summer. I will enlighten him as far as I possibly can on the subject. Mr. Crane paid a visit here some time during last autumn, and the question of deep cultivation cropped up. I pointed out to him the

garden purposes, describe *C. paniculata* as an October-blooming *Flammula*, but bolder and stronger both in mass and in detail. The flowers are alike in shape and in their tender tinting of warm white, but in *paniculata* they are stronger of texture. The leaves are also firmer and stronger, the leaflets rounded instead of pointed, boldly waved and brightly polished, of a full dark green colour, and of firm leathery texture. It grows afresh from the root every year, and although in training it to a bit of fence we remove quite three-quarters of the growth, yet by the autumn it is a dense bowery mass that would amply fill the body of a one-horse cart.

It is of great value for cutting. Quite a large quantity may be taken from one plant without any apparent diminution of its beautiful bloom-masses, and it lends itself most kindly to bold arrangements of table flowers. It is one of our many good garden plants that have come to us from Japan.

NOTES OF THE WEEK.

Hamamelis arborea. For considerably more than a century the only representative of the genus *Hamamelis* in our gardens was the North American Wych Hazel (*H. virginica*), till in 1862 *H. arborea* was introduced from Japan, thus forming another link between the flora of that country and that of North America. The Virginian Wych Hazel, which flowers freely during the latter part of the autumn and in early winter, is, when in full bloom, an interesting subject, but nothing more, whereas *H. arborea* takes high rank as a flowering plant. This is at its best during January or February, according to the season, and when the still leafless branches are thickly studded with their yellow starry blossoms, whose segments are so decidedly wrinkled, it forms, particularly when lit up by the sun, a very beautiful object. If lured out early by unusually mild weather, a severe frost will injure the expanded blossoms, but the unopened buds are seldom affected. Though it attains the dimensions of a small tree, this *Hamamelis* will flower freely when less than 6 feet high. The blossoms are particularly charming when closely inspected; hence in planting they should be so situated that this can be readily done. P.

Monstera deliciosa. I read not so very long ago that at a meeting of the Fellows of the Royal Botanic Society, the secretary, Mr. Sowerby, introduced to the notice of the company present fruit of *Monstera deliciosa*, which I believe it was stated never to have borne fruit in England except at the Botanic Gardens. Now I know that it fruits at Syon House annually, and also at my father's, where indeed a very beautiful specimen may be seen. The *Monstera* is one of the few climbers of the Philodendron family. The fruit is green in colour and shaped like an elongated Pine-apple and the leaves are serrated. After removing the outer coating the succulent part of the *Monstera* is of a most exquisite flavour, but when it has rested on the tongue or reached the palate, a sharp tingling sensation is experienced: this is due to the presence of myriads of needle-shaped crystals composed of oxalate of lime. The plant is indigenous to Mexico and the Straits Settlements, and if the fruit could be exported largely, it would in all probability supplant even such a dainty fruit as the Pine-apple. At present I am unable to write a fuller botanical description, but trust this will interest those who care for tropical fruits. A. GUNTER.

Some new plants in prospect. We receive from M. Max Leichtlin, Baden-Baden, his short but highly interesting list of bulbs and plants, conspicuous among which are some new developments of *Gladioli*. The list is accompanied by a coloured illustration of an individual bloom of one of these, an immense blossom 5½ inches wide, of brilliant scarlet, broadly feathered with white upon the lower petals. On the subject of this list

we have the following note from one of the most watchful and keenly appreciative of our many valued correspondents: "An unusually large number of most interesting new plants are now being offered by Herr Max Leichtlin, of Baden-Baden. Amongst them a new Honeysuckle from Afghanistan (*Lonicera Griffithii*), which he says is very handsome; a North American Aster named *A. Fendleri*; a new *Asclepias*, *A. Hallii*, from Colorado; a most interesting and ornamental plant from Pisidia named *Onopordon bracteatum*, described by Boissier; a beautiful white-flowered Californian labiate, *Monardella macrantha*; three new species of *Berberis*, one of them from Sikkim, the other two from Thibet; three new *Meconopsis*; and the first of a grand new race of *Gladioli* of his own raising which he names *G. hybridus princeps*, and of which he gives a coloured figure. I am getting all these from him, so hope to be able to say something about them some day in THE GARDEN."—W. E. G.

Skimmia Formanii.—A branch of the male plant of this was broken off by the snow on the 2nd ult., and the foliage being so handsome I took it into the house, with the result that it is now (after nearly three weeks in water) in full bloom. From the enclosed flowers you will see what a handsome flowering shrub this form of *Skimmia* is, and you will notice the strong Lily of the Valley scent of the flowers. Not only do the birds spare the berries, but the berries themselves are most persistent, and remain in good condition on the plant for a couple of years, and if grown in a cool house they remain in perfect health for even three years. A. KINGSMILL, *Harrow Wood, Middlesex.*

[The flowers of this handsome *Skimmia* are pleasantly fragrant, but Mr. Kingsmill has omitted to mention (though notice of the fact can scarcely have escaped so good an observer) that the surface of the stems and the crushed leaves have another and very agreeable aromatic odour of a Myrtle-like quality. The whole appearance of the bush is that of an improved *Skimmia ovata*. It was raised by Mr. Forman, of Esk Bank, N.B.—Eds.]

Billbergia nutans. This is certainly less showy than many bromeliaceous plants, yet it forms a decidedly pretty feature in the stove just now, and can be depended upon to yield a good display of its gracefully disposed blossoms at this season of the year. As with most of its associates, the long, slender, gracefully recurving leaves are arranged in a vasiform manner. The flower-spikes, which slightly overtop the foliage, bear a loose cluster of nodding flowers, accompanied by rosy-tinted bracts. The blossoms themselves have the segments prettily reflexed and of a pea-green colour, margined with blue—a striking and uncommon combination. The whole contour of the flower is suggestive of a small *Fuchsia*. This *Billbergia* is a native of Brazil, and was introduced over thirty years ago. Potted in sandy peat with just a little loam, and kept moderately moist at all seasons, it will be just at home. H. P.

Erica codonodes. Far better known by the above name than that of *E. lusitanica*, which is now regarded as the correct one, this *Heath* is valuable from the fact that, should the weather be fairly mild, it will in the open ground flower during the latter part of the winter. It is of a rather erect bush form, reaching a height of 3 feet to 4 feet, or occasionally more, while the upper parts of the branches are now for some distance crowded with little white blossoms, just touched with pink on the exposed side. During severe winters, even in the southern portion of England, this *Heath* is often severely injured, but it generally soon recovers. Anyhow, flowering as it does now, it is well worth a little extra attention, being the most valuable of the larger-growing *Heaths*. For the winter embellishment of a cool greenhouse it readily lends itself, as if lifted carefully from the open ground in the autumn and potted, the blossoms will open without check and form an attractive feature from Christmas onward. Well-budded examples of the *Laurustinus* treated in the same way are very useful, as they can be used in cool, draughty spots where more tender subjects would be severely injured. H. P.

Epacris in bloom. The *Epacris*es, which are just now so attractive, consist of two quite distinct sections; first, the greater portion of the garden varieties which owe their origin principally to *E. impressa*, and are all characterised by slender upright shoots studded for a considerable distance with flowers varying from white to bright red; secondly, those derived from *E. longiflora*, or *miniata*, as it is often called. The members of this section are altogether of a more spreading style of growth, while the individual flowers are longer and drooping, and on the almost horizontally disposed shoots are seen to very great advantage. They are of different shades of red and scarlet, tipped with white. *E. miniata splendens* and *Eclipse* are two good varieties of this section. There is a distinct *Epacris* with quite double blossoms, known as *E. onosma-flora plena*, which has been grown now for about twenty years, and during its early stages it was thought likely to be of considerable decorative value, but it is now rarely met with in a satisfactory condition. Much the same treatment as that accorded to the quicker-growing kinds of *Heath* will suit the *Epacris* well; indeed, these latter occupy much the same position in Australia as their near relatives the *Ericas* in South Africa.—T.

NOTES FROM NURSERY GARDENS.

CHINESE PRIMULAS.

MESSRS. J. CARTER & CO.'S fine strain of Chinese Primulas has for several weeks past presented a brilliant picture in their Forest Hill nurseries, the many fine varieties displaying a charming variety of colours. Among the many kinds we may mention a few that were especially beautiful. *Elaine Improved* is a delicate white, finer than the older *Elaine*; *Hercules* is a pretty carmine-rose flower, to which, as regards the flowers, *Rose* is similar, but is Fern-leaved; *Ruby*, which has crimson-rose flowers, has a unique appearance, owing to the presence of specks round the centre of the flower; *Carmine* is of a rich colour, and a form of this with variegated leaves has been raised, and is, apparently, quite a new departure; *Venus*, which has both the Fern and Palm-leaved forms, is white, variegated with rose. Other good varieties are *Holborn Blue*, *Vermilion*, *Salmon*, and *Rose Queen*, delicate pink. *Carter's Scarlet*, a brilliant kind, and *Princess May* are specially distinct, the latter having very large, handsome flowers of a delicate pink and of good substance. The above are all single kinds, but there are also some excellent semi-double varieties, among which are *Prince of Wales*, *rose*, *Carmine Empress*, and *Aurora*, pale pink.

Messrs. Carter have raised some very beautiful new forms. The crossing of *White Bouquet* and *Carmine* has resulted in two forms, a white and a rose-lilac, the latter of a somewhat more delicate colour than its carmine parent; the flowers are large and distinctly fringed. The result of the crossing of *Carmine* with *Elaine Improved* is a lovely flower, large, and of thick, leathery substance. This also is in the two colours of the parents, white and carmine, the flowers standing well above the foliage. The carmine form has a white halo around the yellow centre, which decidedly adds to the beauty of the flower.

To Messrs. Carter much of the perfection reached in *Primula* hybridising is due. In this nursery are masses of colour of many shades, and the blue forms of both single and double varieties become richer and purer each year. Visitors to the shows know the good work accomplished by the firm in the past, and many treasures are in store in the future. There is improvement all round in the form of the flowers and in the growth of the plant. The Chinese *Primulas* display the result of carefully conceived crossing of varieties to produce improved types, or quite distinct departures from anything previously in existence.

HOME-GROWN APPLES FOR WINTER SUPPLIES.

PROGRESS IN FRUIT CULTURE, BUT TOO MANY VARIETIES OF APPLES.

It is common no doubt with many other readers of *THE GARDEN*, I was greatly interested in the further impetus "W. R." endeavoured to give gardeners and garden lovers on page 51 under the forcible heading "Onward! not Back." Although, as stated, no attempt was made to go over the "whole ground," his remarks anent one section of horticulture, viz., the flower garden, could with equal truth, I think, be applied to other branches, and not the least to hardy fruit cultivation generally, and Apples in particular. There has certainly been an onward movement

Some years ago I remember there was a spirited correspondence in these pages under the heading "Too many varieties of Pears." A similar discussion at the present time might, without doubt, prove valuable on Apples, as the extremely long list of varieties makes it difficult to know which really to choose, there being generally some striking description connected with each to force its sale. If experienced gardeners are sometimes puzzled in making a selection, how much more difficult must it be then for the amateur. Sensational exhibits at different shows are not always trustworthy guides.

One certainly sees the size and appearance of individual specimens, but it is no criterion either as to their cropping or keeping properties, or whether they are suitable for various soils, &c. We have too many early

appear: we have plenty of well-tried ones to go on with that only require to be more freely grown for their full value and usefulness to be appreciated. Which, then, should we select out of the multitude of varieties? Other growers may add to or improve my limited selection. I trust they may, but I only furnish the names of those I have proved to be reliable when, of course, the bloom is not destroyed by late frosts.

CULINARY VARIETIES.

If I were asked to name one good late variety it would be Norfolk Beauty. Here it always crops well, and I find no difficulty in keeping it in grand condition well into May. The same may be said of Northern Greening and Striped Beauty. Hambledon Deux Ans is also a very valuable late Apple, and should certainly be included and planted in all gardens and orchards. To these I would add Lane's Prince Albert and Wellington. Though probably the last two are not quite so firm in texture, they are both valuable for late use, and both are wonderful bearers. I have named sufficient in this short list to maintain the supply as long as it is reasonable to expect Apples to last. I have found them so, and can hardly wish for better fruits.

DESSERT VARIETIES.

In spite of the sharp lookout there has been for new or little-known old varieties of Apples, there still remain in some counties and localities varieties possessing sterling merit, yet their cultivation is to a great extent limited to the district in which they were raised or found, and the country generally (from a fruit-grower's point of view) is the poorer by their not being better known and more frequently planted. As an instance of this I may ask, in how many gardens or orchards outside Worcestershire (or at least the adjoining counties, but Worcestershire in particular) is that valuable late dessert Apple known as Russock Pearmain met with? I do not place this first on my list as being the best, but it is certainly entitled to be classed with them. With late-

keeping dessert Apples we cannot expect to have so large or highly-coloured specimens as seen in autumn, but are the latter always the best as regards quality? They are not, neither are large Apples always appreciated on the dessert table. Who has not eaten a well-preserved Wyken Pippin in the month of March or April and thoroughly enjoyed it, although it is classed below medium size? This variety should certainly be planted more freely or more generally. Then there is another small, but delicious Apple—Nonpareil—seldom planted now, but it would be a pity should such an old favourite go out of cultivation. If we turn to larger fruit of high quality, we have in Claygate Pearmain all that one could desire, and it is in use from November till March. It is a good substitute for the much-prized Ribston Pippin, and the tree is more robust and healthy and less prone to canker. In

APPLE ROOM AT GOODWOOD IN FEBRUARY.

during recent years with fruit culture, but I cannot help thinking that the progress made has been confined in a way to grooves, and that, too, so valuable an article of food should reach far greater development. I refer specially to the Apple.

During the autumn and early winter months there is no scarcity of home-grown Apples as a rule; indeed, there is often a glut; but much of the produce is undoubtedly of an inferior quality. As the season advances first-class samples are none too plentiful in many private gardens, while that on sale has practically been grown beyond our shores. In penning these notes, however, we are more concerned with the productions from medium-sized gardens and a continuous supply for the household over as long a period as possible, and with this there is room for much improvement in most gardens and orchards.

varieties of soft texture, especially in the culinary section. They have also been planted too freely in the past, while more valuable keeping ones have been neglected.

The scarcity of really good winter Apples is no fresh complaint. It has been recognised for years, but somehow the apathy—what else can it be termed?—continues, and after Christmas it is not home-grown fruit which supplies the chief portion in our markets. In this respect we have not made any appreciable progress or onward movement. What have we been waiting for? Certainly not suitable varieties. Favourable soil and climate we also have, while undoubtedly we should feel indignant to be thought less skilful growers than those of other countries. Turning to varieties, we shall always welcome new ones that will stand the test of storage and turn out bright, fresh, and crisp. But there is no need to wait for these to

Margil we have few new ones to surpass it for quality, and it is recommended for planting as bushes in small or medium-sized gardens. Probably the most prolific and one of the best Apples we have in Sussex is Cackle Pippin. Heavy crops are obtained annually, and it is fit for table between January and April. In this list we have not included such as Cox's Orange Pippin, Ribston Pippin, and others that are well known, and which are to be found in most gardens, but selected those which form a succession to them.

I am aware that hardly any I have named would find much favour with the exhibitor, as their size is against them; but I am not dealing with that question at all, but hope to draw attention to some of our oldest and best varieties, which bid fair to lose ground or public favour owing to the introduction of larger and more showy ones; while, again, it is with a view to filling our gardens and orchards with really serviceable kinds rather than with those which may win prizes, but fail to give satisfaction in the most important form, viz., for general use.

Those who require Apples for home consumption during the winter or spring months may rely on those I have named, as a visit to our Apple room at the present time would amply testify.

RICHARD PARKER.

Goodwood, February 19.

RIVIERA NOTES.

ANEMONE-TIDE.

THE time of Anemones has come, and the Riviera is in the full glory of *Acacia dealbata*. The stalls in the market are heaped high with bundles of Anemones gathered to deck the carriages or the bouquets of the combatants in the *batailles des fleurs* that rage the length of the coast from Hyères to San Remo during the Carnival days.

It is hard to believe when one looks on the varied races of cultivated Anemones that they all spring, or are said to have originated, from *Anemone coronaria* and *A. stellata*, for the fulgens section is quite absent from these shores, unless the large gold-eyed "Soleil" Anemone, whose gorgeous scarlet petals used to adorn the terraces near Mentone so abundantly, be considered as the development of the smaller and hardier Pyrenean *A. fulgens*. Be this as it may, the foliage of the "Soleil" Anemone is much more like *A. fulgens* than anything else; it is broader, bigger and stronger, but similar in shape, while much paler in colour. The flower is as large as any *A. coronaria*, but with narrower petals and more of them and is unsurpassed in brilliancy. It is the only Anemone that is not generally hardy in England. I have only heard of its thriving in some sheltered Irish garden.

The chief types, then, of the wild Anemone on the Riviera are the *coronaria* section, with scarlet, purple and lavender petals, the parent of our common garden Anemones; then the Anemone I know as "Soleil"; and lastly, the *A. stellata*, which is the commonest, most variable, and the smallest. Curiously enough, there are many wild hybrids between *A. stellata* and *A. "Soleil"*, while wild hybrids between *A. coronaria* and *A. stellata* are unknown to me.

To my fancy these wild hybrids between the gorgeous *A. "Soleil"* and *A. stellata* are the most delightful and beautiful of all Anemones. The shades of colour vary from richest crimson through shades of rose, salmon-pink and softest creamy-pink to pure white, always with the leaf and eye that show their origin; and for the first time to come across a little valley full of

these exquisite shades of colour is an experience few will forget who love flowers and Anemones in particular. The little valley I possess is full of these shades of colour, and until the later flowering *A. "Soleil"* appeared I was quite at a loss to explain the fact that, while at one end of the valley the *A. stellata* were typical in their shades of lilac, red-mauve and white, the other end, near the groups of the large-leaved *A. "Soleil"*, was rich in shades of rose-salmon and richest crimson. But the puzzles are mending, for who that knows the soft pink Anemone *de Nice*, with its green centre, could believe it to be a form of *A. coronaria*, which its leaves declare to be the case.

The prettiest and most modern forms of garden Anemones are the *Coeur-deau*, with the outer petals broad and generally white, while the centres are fully double, with narrow richly-coloured petals of crimson-rose, purple or green, but these all come much later and are certainly not generally hardy in English gardens. What, I wonder, is their real origin? It would require to be traced back to the Dutch florists, whose earliest triumphs are seen in many a Dutch flower-painter's floral group.

Nice.

E. H. WOODALL.

NOTES FROM IRELAND.

STRAFFAN, CO. KILDARE.

LATE last autumn I had the privilege of visiting these beautiful gardens. It was admittedly not by any means the best season

have been nearly all planted within the last two or three years, and under the ordinary conditions which obtain in most gardens would not have been half the size they are at the present time. Particular note was taken of *Bambusa palmata* in most luxuriant growth; others of special note were *B. japonica*, *B. nitida*, *Phyllostachys viridi-glaucescens* and *P. amra*. These Bamboos are only 1 foot or so above the water-level, whilst at times they are flooded; this fact points strongly to the necessity of an abundance of moisture for their well-being. *Gunnera manicata* amongst these Bamboos is an immense specimen, this fine-foliaged plant finding here an ideal spot. Straffan is noted for its Daffodils in grass; these have been considerably extended, and comprise many of the best and most popular varieties. That fine Snowdrop, *Galanthus maximus grandis*, is also planted extensively in the same natural manner, whilst *Iris reticulata* is planted in thousands, finding here a most congenial home. In walking round the grounds one could not fail to be impressed with the complete absence of all formality, the natural beauty of the position being made the most of. The rainfall at Straffan is somewhat phenomenal. For the year just ended it was 31.89 inches, rain having fallen on 185 days. Under these conditions many of the conifers luxuriate in a remarkable degree, there being fine well-furnished specimens of *Wellingtonia gigantea*, of *Thujaopsis borealis* (a distinct form having the side growths pendulous), with varieties of *Cupressus* and *Junipers*. Deciduous and ever-

FLOWERING PLANTS IN STONE WALL AT STRAFFAN

of the year for inspection, but to the garden-lover there was an abundance of good things to be seen and taken note of. The gardens at Straffan are beautifully situated upon the banks of the Liffey, which river takes a meandering course upon the western side, dividing into two channels nearly opposite the mansion. The island thus created forms part of the pleasure grounds, and is an ideal spot for semi-wild gardening. Bamboos are to be seen thriving here in the wildest luxuriance. These

green trees and shrubs are found here in great variety. The Tulip tree is a remarkable specimen, better furnished than many examples; it is also extremely floriferous, almost every point of growth bearing a flower. In a sheltered nook is to be seen *Magnolia purpurea* Lenné, the finest specimen probably to be found in any garden. *Pernettyas* are perfectly at home in well-prepared beds, producing their berries in many colours and the greatest profusion. Another fine specimen is *Cotoneaster*

frigida, some 20 feet or so in height. *Azara microphylla* is perfectly at home, and so are the brilliant forms of *Acer palmata*. Of *Choisya ternata* there are dense bushes. The Wych Hazels (*Hamamelis arborea* and *H. japonica*) thrive well, and the same can be said of the *Cydonias*, notably *C. japonica rosea*. Amongst other evergreens, the Weeping and Silver Hollies are fine features. By the banks of the Liffey the Willows and Dogwood produce a most beautiful effect. Both spring and summer bedding is done extensively; but for once, after many years, the beds are for this

"IN A SMALL WAY."

NOTES FROM AN OBLONG GARDEN.—II.

February 1.

DEEP snow! and very seasonable, too. Last year everything rushed out all through a beautiful warm February, and suffered terribly from six weeks of east wind a little later, with the result that my Roses were a miserable first crop. This year I see *Clematis Jackmani*, both *alba* and the *blue superba*, have fat green buds in their joints, all ready to burst and be nipped, for they were foolishly produced quite early in

A GROUP OF A HARDY LADY'S SLIPPER (*CYRIPEDIUM SPECTABILE*) AT STRAFFAN.

spring to have a rest. Note was taken of some Dahlias with their stems quite bleached which were cut off by frost early in September, so liable is this spot to early autumn and also late spring frosts. In spite of this, however, both Apples and Pears are finely grown; better coloured examples we have never seen, or tasted finer flavoured Cox's Orange Pippin. Of Pears, Marie Louise is one of the finest, other good kinds being Beurre Rance, Winter Nelis, Josephine de Malines and Thompson's; these are all grown upon walls, chiefly facing south. Peaches are very fine under glass, without heat, and are well-balanced trees. The ranges of glass are extensive. Orchids and other choice plants having been features here for many years past, but owing to the death of the late proprietor several of the finest specimens have been removed to another seat of the family. One can fully sympathise with Mr. Bedford in thus having to part with plants that he had made especial favourites for years past. It will not, however, be very long before their places are again filled, as gardening in all its varied phases is carried on with spirit at Straffan. Writing of Orchids reminds me of the superb mass of *Cyripedium spectabile* which thrives there to perfection. A good example is afforded, too, of how to clothe a wall with alpine plants. This is done by forming ledges upon the side of the wall, the plants chosen being evidently quite at home.

JAMES HUDSON.

Gardeners' Royal Benevolent Institution. We announced lately that the Duke of Bedford would take the chair at the next anniversary dinner of this deserving charity, but it should have been the Duke of Portland.

January. So has the Montan Peony, which grows in front of the *C. alba*. Of course it has had several pinkish plump noses ready all through the late autumn and winter, but during the last week or two it has unfolded them a good deal. It is not planted in the best of situations, for it is in the sunny border, which gets the full benefit of his majesty from the earliest of his uprising, and all the books warn us against planting Peonies where night-frozen buds and early leaves will be too quickly and fiercely thawed. There is the Lord Suffield Apple tree in the lawn close by though, and I hope this will be some slight protection, though I feel myself as foolishly sanguine as the *Clematis* is premature. What a pity it always seems to cut down the summer and autumn-flowering *Clematis*es to the regulation five or six eyes in the winter before they sprout! I confess I have not done it to mine, as although, when left unpruned, the growth retreats upwards to some extent, leaving a certain amount of bare stem below, some of the new shoots can always be tied down to cover the nudity, even supposing the plant does not see to this itself, as I find it usually does with a perfect mantle of wealth. I had *Clematis montana* planted last year against the half-shady wall where a group of Lilac bushes grows in the next-door garden; they are old and very tall, and have been kept strictly to their own side, so that the side next us presents a very suitable position for my *montana* to climb upon and wreath itself round the Lilac branches. Close by I put *Clematis flammula*, as I thought they might grow up together, and then our eyes would be blessed with sheets of starry white blooms both in spring and autumn. Although the *Clematis flammula* is only a

baby, between 3 feet and 4 feet high, it bloomed most profusely not long after it was turned out of a pot into the ground in late September. It smelt most deliciously, and then I thought no more of it, until November—quite at the end of the month I noticed it looking filmy and smoky, with a gleam of red; it had covered itself with the same delightful grey-feathered seeds as the common Traveller's Joy, but more beautiful, because the seed itself among its plumes is crimson. There is no such country as this for Traveller's Joy: it hangs in vast masses, and drapes all the dear untidy high hedges like the smoke of battle, and as it flourishes so exceedingly, so I hope may its near relations in my garden. This is a good month for planting them, and I have ordered new plants of Princess of Wales, which is a most lovely deep mauve late bloomer, and the two doubles, respectively lilac and white, Countess of Lovelace and Duchess of Edinburgh, of the Florida section. I have always failed with these, for in our damp winter they will die off, apparently near or about the graft, but I cannot buy them on their own roots. A friend of ours has a superb Countess all over the front of his house, and every year when I drive past and see it, I mentally devote another 1s. 6d. or 2s. 6d. for a specially large plant to a fresh purchase and trial. One thing I have established—none of these tender kinds will grow here on arches. I am going to try them on the little shady recesses where the small buttresses are that support the walls of the oblong; if I put them in on the side where the sun cannot get at their lower stems when they are wet, but where the shoots can go over and get all they want of sunshine, perhaps I shall do better. The effect of these things by themselves on a wall is not quite satisfactory, so I am giving them a background of small-leaved Ivy, a kind of which I am ashamed to say I do not know the name, but it has a pink and silver leaf, with a little faint green about the midrib, and is a *peevish* grower in most places, though it seems happy here. The aurea spectabilis Ivy is beautiful over the side of a house near, but I am afraid the one I have planted in the half-shady wall as a background to the yard and a half of border devoted to Iris germanica will not show enough gold to deserve its name. The soil is too good, and nearly all its new leaves are green.

The snow has come at an annoying moment, for one thing—my plantation of pardalium Lilies now in making. I have never seen them growing, for about here no one seems to go in for Lily culture, but a coloured picture of the Tiger Lily-shaped blooms, rather more slender and graceful, with the green-tipped petals, all spotted like a newt's stomach, fired me with desire of them, and I ordered a dozen, to receive which we have made a nook at the very far end of the shady border. A Laburnum tree, quite an infant, bends over a little here, but if it interferes I shall have it taken away. The angle is full of Ivy, and the wall at the back is covered with a white rambling Rose, which goes over the top to get sun. I had a hole dug 2 feet deep and about the same square. As the drainage seemed good, we put a little old hotbed manure and fibry loam at the bottom, and then filled in with peat and loam and just a sprinkle of sand. It is never very dry down here, and I have a wee plantation of Trilliums close by, which like the same kind of life as the Panther Lily, and the big old Apple tree will shade them. The pardaliums are to come from my favourite nurseryman, who will charge a little more than advertised prices and pick them out for me. He says that the Lily disease is now rampant among all the Japanese imported bulbs, and advises me to get auratum, &c.,

either home-grown or from Holland, where they are not troubled as yet. The English-grown *auratum* will often grow perennially in the garden, whereas foreign bulbs seldom or never survive their first season, so it is well to be economical here by being extravagant to begin with.

M. L. W.

Bathwick, Bath.

ZYGADENUS MUSCÆTOXICUM. (FLY POISON.)

THE *Zygadenus* are not very widely known to growers of hardy flowers, nor is it surprising that this should be the case. They do not appeal to those who like bright colours, and nurserymen are apt to fight shy of such flowers, as not likely to make profitable stock. Thus they do not often meet the eye of those who visit nurseries or flower shows. They have, however, beauties of their own which commend them to the increasing number of those who can see that bright colour does not constitute the only charm of a flower. Their synonymy is rather difficult to follow, as *Anianthum* and *Anticlea*, with some of the genus *Helonias*, have become merged in *Zygadenus*. They belong to the Lily family, and, with the exception of one species, which is found in Siberia, are natives of North America. They have rhizomatous or bulbous root-stocks, long, linear leaves, and simple or paniced racemes of flowers, which are mostly tinged with green.

The species shown in the accompanying photograph of *Zygadenus muscætoxicum* is generally found under the name of *Anianthum muscætoxicum*, and will probably be more easily procured under the latter name. It is a very ornamental plant with its fine racemes of white flowers slightly tinged with green. It has not the best reputation for hardiness, but I think this is largely owing to its being destroyed by slugs when making its young growth. It is usually advised that it be grown in moist soil, but I think this a mistake in damp districts.

The plant here figured was grown in the garden of Mr. John Maxwell, Maxwelltown, Dumfries. It shows what can be done with hardy flowers in the gardens of country towns. That of Mr. Maxwell is almost surrounded by houses within a short distance, and is quite close to works whose chimney-stacks emit a good deal of smoke daily. This plant was placed in a bed of fresh soil about 2 feet deep,

and composed of sandy peat to which bone-meal was added. The first winter it was protected with a hand-light, and came away well and flowered. The following year it was left unprotected, and produced the flowers shown in the photograph. In the same district several other growers of hardy flowers have also been very successful with this *Zygadenus*, but I have not seen any finer than that of Mr. Maxwell.

S. ARXOTT.

Carsithorn, by Dumfries, N.B.

HOW PLANTS CLIMB.

THE questions naturally arise, why do some plants climb? and how have they acquired their climbing properties? A possible origin or cause may be suggested by overcrowding, when certain weaker plants, utilising the common property of circummutation, and

FLY POISON (ZYGADENUS MUSCÆTOXICUM) IN SCOTLAND.

acquiring a greater degree of sensitiveness, become stem-twiners, leaf-climbers, &c. Circummutation and sensitiveness are universal properties in plants in varying degrees; thus, they both may be seen in germinating roots. The former is exhibited by germinating roots which bend to all points of the compass as they elongate. It is well seen in the terminal shoot of a Fir tree, which, if observed from time to time, will be noticed to have changed its direction, until it finally straightens itself below and remains erect, the apex, however, still continuing to mutate. This shows that there is a certain antagonism between lignification, or the consolidation of tissues, and circummutation, so that as soon as a stem becomes rigid by strengthening itself,

circummutation tends to cease. Consequently, if stems be weak when overcrowded, they might continue to circummutate when growing to greater lengths, and perhaps such conditions might be favourable for an increased sensitiveness, but of this we know nothing.

Climbing lianas in tropical forests often take the forms of ropes and bands, which completely invest the trees in an inextricable network, and a feature which has long been observed is the anomalous nature of the woody stems of such climbers. They belong to several families of plants, and, generally speaking, their peculiarities are characteristic of their families respectively. Thus, in the Malpighiaceae the tendency is to make the wood deeply lobed by excessive growth at certain points on the circumference instead of uniformly all round. Then, as the twining stem becomes twisted, a result of continued growth after the stem has become linked to another, it now exactly resembles, and, indeed, acquires the strength and flexibility of, a stout cable of many strands. It is difficult not to entertain the suspicion that Nature has been following the example of man in making a strong rope out of what would be when isolated a number of weak materials. As the lianas are necessarily subjected to all sorts of strains, the cable-like form is admirably suited to their requirements.

The genus *Bauhinia* of the Leguminosae and its allies are like broad ribbons, as the stem increases only on the ends of a single diameter; but besides this flattening out the ribbon bulges alternately first on one side, then on the other, thus affording great additional strength, while in some cases, like the so-called Monkey's Ladder (*Cantolretus*), wing-like appendages are added to the sides. In others, though the stem may be round, on a cross section being made, the wood is found to take the form of a cross, with large medullary rays of softer tissue intersecting it. However anomalous the wood may be, certain common features prevail, in that there is always a feeble lignification of the wood fibres, with which are associated very many and large vessels or long tubes. The usefulness of these two features is, in the former, excessive flexibility, and in the latter an easy means for water to be conveyed with great rapidity to the enormous lengths over which it must necessarily run to reach the foliage.

English climbers are mostly herbaceous, *Clematis Vitalba*, or the Traveller's Joy, and *Honeysuckle* almost alone possessing anything of the nature of a woody stem; but these, as also a six-year-old stem of the Bittersweet (*Solanum Dulcamara*), exhibit just the same features in being excessively flexible and provided with many vessels.

Climbing plants may be grouped as follows: Those which climb by their stems or twiners, by branches and by leaves. (1) by petioles, (2) by leaf apices, (3) by midribs modified as tendrils, (4) by peduncles and pedicels as tendrils; hook climbers—(1) as branches, (2) as leaflets, (3) as peduncles, (4) as cortical prickles, (5) as epidermal acicular processes; lastly, there are aerial root climbers.

As a great variety of these are described by Mr. Darwin in his work on "Climbing Plants," it is unnecessary to give details here; but what one wishes to suggest, if possible, is the cause of the production of these different structures.

The old idea was that they, as indeed all adaptive structures in both the animal and vegetable kingdoms, were designed, *i.e.*, in anticipation of their use. This view cannot now be entertained, and we must look to the reverse process for their origins. That is to

say, instead of a climbing organ being made before the plant climbed, we now regard it as a result of having, if not actually climbed, of at least of having come in contact with some foreign body. To show the tenability of this view we have first to observe the extreme sensitiveness to contact which exists in plants. Thus, a loop of thread weighing a quarter of a grain is sufficient to cause the petiole of *Clematis montana* to bend; and when an organ has caught a foreign body and remains in contact with it, this sensitiveness compels it to develop extra tissue to an extraordinary degree. Thus, the petiole of *Solanum jasminoides* has three fibro-vascular cords on the lower side, but after clasping, the wood forms a complete zone as in an ordinary stem. Similarly, hooks, if they catch anything, thicken and enlarge out of all proportion to the size attained by non-clasping individuals. Thus one arrives at the conclusion that sensitiveness causes a climbing organ first to twist round its support, and secondly to thicken. From these facts one deduces the origin of the form of the organ, say the tendrils of the Pea. It consists of the midribs only, which are now highly sensitive. As a leaflet acquires this property, so in compensation the power to make the flat blade ceases. An intermediate condition is seen in *Corydalis claviculata*, described and figured by Mr. Darwin, in which the leaflets exist in all stages of passage, from a full-sized and non-sensitive blade to nothing but a highly sensitive midrib.

The course of development, then, seems to be as follows: First, by circumnutational contact is maintained, then supersensitiveness is excited; adaptive growth and development, with alteration of structure, follow, and the climbing organ is finally produced in the course of generations. When once formed, the organ, with its properties, becomes an hereditary feature.

As good illustrations of this last result are the two commonly grown species of *Ampelopsis*. *A. hederacea* (the Virginia Creeper) has a tendril constructed out of a flowering branch. It makes the feeblest attempts to climb round any foreign support; but as soon as the little hook-like extremities of the branchlets of the tendril can catch any roughness in a wall, the effect of contact is soon seen. Not only do they swell into little pads, but secrete an adhesive substance, while the branchlets curl up like irregularly-formed corkserews and thicken greatly. That all this is the actual result of contact is seen by the fact that if any tendrils fail to secure a hold they soon fall off.

In *A. Veitchii*, the Japanese species, the tendrils have their pads already partially developed in an immature condition before any contact is made at all, so that the one species throws light upon the other, in that not only is the power to produce the pads hereditary (as in *A. hederacea*), but the actual result has become anticipatory in the latter species—just as an eye is formed before it can feel the effect of light.

The climbing property, having become inherent in the constitution and hereditary, may be held in abeyance, but be still potentially there. Thus dwarf French Beans make strong stems and have no need to climb; nevertheless, they occasionally throw out a long shoot which twines round any support. *Convolvulus arvensis* (the Lesser Bindweed) climbs up the stems of wheat in a cornfield, but makes no effort to do so when crawling along the ground on a sunny bank. Perhaps the most remarkable case is a tree called Hiptage. This is grown in gardens in Cairo. It has a fair-sized trunk, with thick branches. Suddenly a long

whip-like shoot appears and twines up anything it can come across. As it belongs to the order Malpighiaceae, which has several climbing lianas, it is a tree whose ancestors evidently were accustomed to climb, and has retained the power, though it is quite useless, for the tree is perfectly well able to support itself.

GEORGE HENSLAW.

THE KITCHEN GARDEN. FORCING TURNIPS IN SPRING.

THIS vegetable was not forced much years ago, the chief reason being that when similar treatment was given to it as to other vegetables it failed, and the return was not equal to the time and cost bestowed on the plants. Another difficulty was the want of a variety, as some of our older varieties do not force well under glass, as they run to seed badly if much heat either at the root or otherwise is employed. Turnips are always valuable in the spring, as the roots of last year's crop, no matter how well kept, lose their flavour and grow out badly, so that young sweet roots are in demand at that season. Now is a suitable time to sow under glass for a spring supply. This vegetable forces very quickly, as the seeds in a warm soil germinate so readily. If possible, I advise sowing in frames, as grown thus the plants are so much nearer the glass and suffer less, as they draw badly and come weak and spindly if needing light and air. Free ventilation in favourable weather is an important point in their culture, as any coddling of the plants will probably end in failure.

Many may think the Turnip not worth forcing, but when it can be grown with so little trouble and there is no great choice of vegetables at the season named, they are profitable and most useful. As previously stated, excess of warmth at any time is not advisable. In our own case we rely largely upon fresh leaves as the heating agency for the roots, but bottom-heat is not a necessity if the plants are grown in a frame that is heated so that cold and frost may be kept out. With a mild bottom-heat the seeds germinate more quickly, but there is more care needed afterwards to prevent running to seed. Excellent roots may be grown in a cold frame without fire-heat or manure if a little extra care is taken at the start, covering the glass at night to exclude frost, and closing early in the afternoon in mild weather. Sown at the end of February or earlier, there will be roots fit for use in less than ten weeks, and with the aid of a hot-bed at the start growth is rapid, but care should be taken to prepare the heating materials so that the rank heat and steam are got rid of before sowing the seed. The soil should be light and good and should be made firm when sowing, and when once growth is active, moisture and air should be given freely on all favourable occasions.

I have referred to the newer types as most suitable. Carter's Early Forcing is reliable, and differs from our ordinary roots in being of a long, oval shape, a rapid grower, and less likely to run to seed than the round roots. Another variety is Sutton's White Gem, a beautiful root, oblong in shape and of splendid quality. This I have forced in heat with greater success than most kinds, and few are more valuable for sowing in an early border in the open for first supplies. The Extra Early Milan is the best of the flat-rooting, round varieties, but the quality is not equal to White Gem, and the latter is a specially good variety in light soil in a dry summer. There are some good French varieties; the one named *Naveet a forcee long blanc* is a splendid forcing root more like a large, long Radish than a Turnip. The *Naveet Marteau a collet rouge* is equally good, but needs a little more time; so also is *De Frenense*, a thin, tapering root and very early. All the above force freely, and are reliable when grown under glass or given protection in early borders.

G. WYTHES.

TURNIP CARTER'S NEW EARLY FORCING.

This valuable Turnip, introduced for the first time last year by Messrs. Carter and Co., is the finest variety for frame culture that I know. If sown now and onward on mild hotbeds in frames, splendid young Turnips may be had in a very short time. Its great value over other early kinds which I have tried for this purpose is that it remains fit for use for a much longer period than others. Young Turnips are generally much appreciated in most establishments, so that this when well known should prove a great gain.

F. B.

NEW ZEALAND SPINACH.

This distinct and useful vegetable should find a place in every kitchen garden. Few things will stand a continued spell of dry weather better than this, and its true value must have been proved over and over again during the past dry summers, as it makes a tasty dish and a first-rate substitute for the real Spinach. It thrives best on an open south border where it can enjoy plenty of sunshine, and a light porous soil suits it best. It is very tender, and may either be raised in heat and planted out, or sown in the open towards the end of April. It is a very robust-growing plant, and should be planted or sown in rows 3 feet apart, allowing a distance of 2 feet 6 inches between the plants. A good bed of this is very pleasing to look upon when growing, and also very prolific.

E. BECKETT.

SAGE.

AMONGST herbs, Sage is one of the most frequently asked for. It sometimes happens that a fresh supply is wanted, and must be obtained from someone in the trade, or it may be from seed, as this is a good method to obtain a strong, vigorous stock. In this case, there is a danger of obtaining a bad variety. Two distinct kinds are met with—the red, or narrow-leaved, and the broad, whitish-green-leaved kind. The former is not worth growing compared to the latter. A few years ago, when I took charge of this garden, I had to resort to obtaining a fresh stock from seed, and by so doing used the red, or narrow-leaved. It grew away and was planted out and allowed to make big bushes. Never growing it before, I was not hasty to condemn it. During this time I obtained cuttings of the broad-leaved, rooting them in spring, and we have now an abundant supply. Now I have resolved to destroy the red, as the leaves droop in early winter, except a few at the tips of the shoots. Everyone should strike cuttings occasionally to maintain young stock.

J. CROOK.

CHINESE ARTICHOKE.

(*STACHYS TUBERIFERA*.)

SINCE the introduction of this distinct vegetable about ten years since from North China—it was then looked upon as a mere luxury—it has steadily become more popular, and is now to be found in most well-ordered kitchen gardens, and when properly cooked it forms a most delicious dish during the winter months. I have found it to succeed best on a west border which has been thoroughly trenched and manured the season previous, and the most suitable soil is a light sandy loam. The tubers should be planted during March, allowing a distance of 1 foot between each set and 18 inches from row to row. Plant with a suitably-sized dibber 3 inches deep. Hoe frequently as soon as the growth is above the ground, which will greatly assist the vigour of the plants, as every inducement should be afforded them to produce tubers as large as possible. Frequent drenchings of both clear and manure water in dry weather will also greatly help to this end. By the beginning of October the crop should be fully matured, when they may either be lifted and stored in sand or taken up as required; but sufficient should always be stored by in case of a spell of frost, or they will be found very troublesome to procure.

E. BECKETT.

AN ARTIST'S NOTE-BOOK.

IRIS DANFORDLE.

THIS is one of the most beautiful of all the early Irises; the bright yellow flowers with their quaint green markings at the base of the falls present a most distinct appearance. When established on the rockery with *Iris Bakeriana*, *Histrio*, *persica*, *reticulata*, &c., and those of a similar nature, it forms a perfect picture in early spring. This species is quite hardy, and is a native of Asia

IRIS DANFORDLE.

(From a drawing by H. G. Moon.)

Minor. Though introduced, however, some ten or twelve years ago, it is rarely seen, but of late it has become more plentiful and easily procured; it does best in a light, well-drained sunny position. It was first shown by Mr. R. Wallace, of Colchester, before the Royal Horticultural Society in 1891, when it received a first-class certificate. The drawing was made from a flower selected from Mr. Wallace's group at the last Royal Horticultural Society's meeting in the Drill Hall. These early bulbous Irises are very easily grown in pots for conservatory decoration. The bulbs should be potted in early autumn in light rich soil, plunged in a cold frame, and introduced into a cool greenhouse early in the year; they soon come into flower, and do not want much fire-heat. After flowering, replunge or plant them out if the weather is not too severe.

BRODLEA SELLOWIANA.

This new and distinct bulbous plant has recently been introduced from Uruguay, and has been in flower for some weeks past in a cool greenhouse in Mr. Worsley's garden at Isleworth, and also at Kew. The plant altogether is not more than 6 inches high. It has narrow, deeply-channelled grassy leaves 6 inches to 8 inches long, all more or less recurving, and

with the channelled side turned under, a position somewhat difficult to account for. The blossoms are about $1\frac{3}{4}$ inches across and of a uniform bright golden yellow, with the exception of a green keel on the outer surface of the ovate-acute perianth segments. The flowers are borne singly on the scapes and are sweetly fragrant. Unfortunately, however, they only expand about the middle of the day and when the sun is shining. At other times the segments approach each other, and remain in a more or less closed condition.

Although it has not yet been proved by experience, it is possible that this species may prove as hardy out of doors as the well-known *Triteleia multiflora*, of which it may be taken as a yellow-flowered counterpart. To prove effective it would have to be planted in large patches, and if grown side by side or mixed with *Triteleia multiflora*, would make a charming spring picture in the flower border or on sheltered sunny banks. J. W.

CAMELLIA LADY BULLER.

Not many years ago the Camellia was one of the most popular of garden flowers, but of late years flowers of more graceful form have taken its place. Probably, as fashion is as changeable as the weather, the Camellia will again be grown in English gardens. Certainly such varieties as the one portrayed in the accompanying sketch will help forward to this end. It was shown by Messrs. Sander and Co. with some other kinds, two beautiful flowers being Lady White, white with red splashes, and Lady Roberts, pink with white edge. The variety Lady Buller is a handsome flower, large, with broad petals of a pleasing rose colour.

NOTES FROM SCOTLAND.

A WINTER GARDEN IN GLASGOW.

THE corporation of Glasgow is about to erect another winter garden to be located in the Springburn district of the city. While thus providing the purest of human pleasures for its teeming, toiling people, the second city is at the same time not unmindful of the wants of the gardeners to whose skill and industry the success of its parks and gardens is due. The superintendent, Mr. Whitton, has been entrusted with the formation of a library of books devoted to gardening and pursuits of a kindred nature for the use of his staff. The collection is not being confined to modern books, and already a selection of early works on gardening has been brought together. Glasgow's record in gardening of late years has been altogether praiseworthy.

THE SUPPLY OF YOUNG GARDENERS.

During the last few years the supply of young gardeners in Scotland has barely met the demand, but never previously have they been so scarce as at the present time. At the November term nurserymen were compelled to

advertise for men to send to their clients. The scarcity is due largely to economic causes, there being a constant demand for unskilled labour at big wages in the iron districts. This draws young men away from the garden. But that is not the only cause; a distinctly less number of apprentices than formerly being now kept in gardens also exerts a marked influence on the supply.

APPLE LADY KINLOCH.

MESSRS. R. B. LAIRD & SON inform me that Messrs. Pearson, of Chilwell, have taken over the stock of their Lady Kinloch Apple. This is a late dessert variety of Ribston flavour which was raised in 1878 by Mr. John Brunton, Gilmerton, East Lothian. It received a first-class certificate at the Edinburgh Apple Congress in 1885, and since then has been on trial in gardens in different parts of the country. The late Mr. Dunn, of Dalkeith, thought highly of its qualities, and if, like James Grieve, it proves in the south as satisfactory as that splendid early-eating variety, Scotland will be prouder than ever of her Apples.

THE TRUE WHITE-FLOWERED EAST LOTHIAN STOCK.

This is now difficult to procure. I remember it twenty to thirty years ago, with long compact spikes not unlike the equally scarce Scotch Rocket, when it commenced flowering in July. Now it is a not uncommon experience to be supplied instead with a variety that does not bloom till the second year. Scotch readers who possess the true variety ought to cherish it and secure every seed possible.

"A the months o' the year,
Curse a fine February."

BRODLEA SELLOWIANA.

(From a drawing by H. G. Moon.)

This Scots "saw" will not apply to the present "February," and the outlook for the garden is decidedly gloomy, not only now and in the immediate future when the effects following zero temperatures come to be realised, but still later when the crops that cannot be sown or planted are missed. It is not too late even now to sow emergency crops of Peas, Beans, Lettuces, and Cauliflowers in cutting boxes which, placed in a warm temperature, will germinate quickly, and planted out when sufficiently strong will yield at the usual time, or perhaps earlier. Early Potatoes may also be arranged in flat boxes with the growing eye upwards, and good progress effected while waiting an opportunity to plant in the open.

Even such unlikely subjects as Carrots and Turnips sown now and transplanted into the open ground in April will not only grow, but will prove extremely useful where no means exist of producing them under some protection. Peas and Beans may be sown, the seeds touching each other so that sufficient to provide for a full early crop takes up comparatively little space. They must, of course, not be in any way forced, and if the soil in the boxes is preserved in a somewhat dry condition, the seedlings suffer no check when lined out singly. The others must be sown rather thinly.

WOODLAND AND FOREST.

LOWLAND FIRS.

WHAT a lot of nonsense has been written from time to time about the Scotch Fir producing excellent timber in the Highlands of Scotland only, and being worthless everywhere else. Now-a-days one feels as if they could not believe anything but what they can see and feel themselves. It is a foregone conclusion with most planters that the timber of the Scotch Fir, grown in England or the Lowlands of Scotland, is next to worthless, or at the best only fit for the roughest estate purposes. Hence the reason why the tree has been so sparingly grown in England, while it has been planted to the exclusion of more valuable trees in the Highlands. No doubt climate makes some difference to trees. Where the climate is wet and the sunshine least the texture of the wood of timber trees will be inferior, comparatively, but nowhere in these islands is the difference so great as to convert a good timber tree into one quite worthless. The Germans and the Dutch regard the Scotch Fir as a tree of the plains, as thriving best in warm exposures in mountainous countries; and in Holland, where it is extensively planted in the rising forests there, the plantations are not much above sea level.

In England at one time the Scotch Fir must have been plentiful and of fine quality. Some years ago I saw taken out of an old church tower that was undergoing repairs a beam of Scotch Fir about 15 inches square that must have grown in the neighbourhood some 250 years ago.

It was still sound in the heart, although worm-eaten at the outside. The beam had not been sawn, but only squared by the axe roughly, the bark being still on the corners at some places. In Worcestershire the other day I found examples of the same kind. Some very fine old Scotch Fir trees are to be found in that county resembling in leaf, colour of the bark, and general appearance some of the finest examples to be found in the Highlands of Scotland. Coming in contact with a country builder, I inquired if the timber was ever found in old houses in the neighbourhood, and was assured that he had often removed very old beams of Scotch Fir from old houses, both joists and rafters, and he told me of some old inns where I could see the same for myself. Oak predominates, but the extent to which timber has been used in building in Worcestershire in former times shows that the supply must have been large and run upon till exhausted. In such towns as Droitwich, in villages, farmhouses, and mansions, timber has been extensively employed, in many cases the entire framework of the building, including the walls, consisting of timber, and apparently home-grown Oak and Fir were principally employed. The Scotch Fir is certainly at home in Worcester and Hereford, and timber from 40 to 100 years of age might be a profitable crop.

As might be expected, the Larch is at home in the same places, for where the Scotch Fir will succeed so will the Larch. Both love a well-drained soil and a not too moist climate. There

are some fine Larches in Hereford and neighbouring counties—old trees—and the young plantations up to thirty years of age are the healthiest I have seen for a long time—just at the stage when the disease is usually worst, but quite free from it. The Larch may prefer hills and elevated aspects, but it is also a lowland Fir. For many years back, to my knowledge, some of the large collieries in South Yorkshire have been wholly supplied with Larch from the Lincolnshire flats where the soil is favourable. This is fine red-hearted stuff used for strong props and a variety of purposes in collieries where the Norway props cannot be relied on. Larch is still being planted in Lincolnshire extensively, the Earl of Yarborough being, I believe, one of the most extensive planters—a rather singular thing when one considers that Larch planting is almost being abandoned in its once favourite region, the Highlands of Scotland, for fear of the disease.

Where the Larch and Scotch Fir will grow, the Corsican and Austrian Firs and Japanese Larch will do equally well, but the two first might be the most profitable to plant. In Leicestershire I have known plantations of Larch, on a loose, pebbly soil, in which the annual growth of many young trees exceeded 4 feet. I sent one leading shoot, 4 feet 4 inches long, to a friend in Edinburgh who had been writing about a Douglas Fir shoot not quite so long. I have often seen Larch one-year-old leading shoots 3 feet long, but 4 feet is exceptional, and I think 3 feet is seldom obtained at high elevations.

(From a drawing by H. G. Moon.)

ORCHIDS.

TWO INTERESTING
CYPRIPEDIUMS.CYPRIPEDIUM SCHLESINGERIANUM VAR. MONS.
DE CURTE.

THE original cross between *C. Boxalli* and *C. insigne* first flowered in the nurseries of Messrs. Seeger and Troppat Dulwich, and was described in THE GARDEN for January 24, 1891, under the name of *C. Schlesingerianum*. Since that time many crosses between *C. Boxalli* and *C. insigne* have flowered. Owing to the many variations of these species, the different offspring have proved still more variable. Many have been considered sufficiently distinct to give names to, but on the Continent, in America, and also in our own country they have been christened without regard to the original name of the *C. Boxalli* and *C. insigne* cross. Many eminent botanists consider the species *C. Boxalli* as a variety of *C. villosum*. I have no doubt that botanically they are correct, but the scientific view and the practical sometimes disagree. Although it may only be regarded by the specialist as a geographical form of *C. villosum*, it is sufficiently distinct for garden purposes to merit a name. *C. Boxalli* and *C. villosum*, it must be remembered, are both used for hybridisation, and distinct features have been derived from the use of each, whilst a larger proportion of superior forms have been procured from the use of *C. Boxalli* than in the case of *C. villosum*. Anyone interested in the results may soon satisfy themselves on this point if the various lists of hybrids are consulted. I will only take the cross between *C. villosum* and *C. insigne*. This has been effected with many of the better forms of *C. insigne*, and resulted in distinct forms of *C. nitens*. But none of the flowers are so finely spotted and of such great substance as those from the *C. Boxalli* and *C. insigne* crosses. The subject of the accompanying illustration, *C. Schlesingerianum* var. *Mons. de Curte*, is derived from the intercrossing of *C. Boxalli* and *C. insigne* Chantini. It was raised in the establishment of M. Vervaeet at Ghent in 1893, and has since been raised in several instances in this country. I recently noticed one of the best forms of this section I have seen in the garden of Mr. W. Cobb at Dulcote, Tunbridge Wells, the dorsal sepal measuring nearly 3 inches across. In these, as in most *Cypripedium* hybrids, there is considerable variation. In most of the forms the dorsal sepal is broad and of fine substance, white at the top with some purple spottings, the basal portion being green, sometimes suffused with brown and thickly covered with large dark brown spots. The finely-shaped petals have a greenish yellow ground colour suffused with brown and

sometimes spotted with a darker shade. The highly polished lip is deep brown, shading to greenish yellow. These hybrids retain the free-flowering characteristics of the parent species, and are also of vigorous constitution, whilst they are useful for their winter-flowering character, lasting a long time in perfection. The plants can be easily accommodated under cool house treatment, where a temperature of 50° is maintained at night during the winter months of the year. The flowers are altogether finer when grown under cool conditions. Our illustration is taken from a photograph kindly sent by Mr. G. W. Law-Schofield, Newhall Hey, Rawtenstall, taken by him from a plant in his own collection, Mr. Law-Schofield having one of the finest collections of *Cypripediums* and other Orchids in the north of England.

CYPRIPEDIUM MONARCH.

This interesting hybrid is the result of intercrossing *C. Spicerianum* and *C. Lathamianum*, the latter being a hybrid derived from *C. Spicerianum* and *C. villosum*, and is one of the few successful hybrids that have been procured from the use of *C. villosum*. As might be expected, *C. Monarch* has much of the character of *C. Spicerianum*. The fine-shaped dorsal sepal is white, suffused slightly with rose, with a small area of green at the base. The characteristic brown-purple band of the *C. Spicerianum* hybrids through the centre is most pronounced. The fine-shaped petals are greenish yellow suffused with brown, the highly-polished lip deep yellow, with a light suffusion of brown. This photograph was also kindly sent by Mr. G. W. Law-Schofield. H. J. CURRYAN.

THE FLOWER GARDEN.

CARNATION GROWING IN
AMERICA.*

SO extensively is the Carnation grown in the United States, and to such a state of perfection has its cultivation developed, that a few remarks on the system there practised may be of interest perhaps of service—to British growers of that beautiful flower.

The American Carnation varieties are, of course, descended from plants imported from Europe, though they have developed into a perfect American type. The cultivation there does not date far back, for only during the last twenty years has it been really pushed. Judging from the accounts older growers give of the quality of blooms produced fifteen years ago, one marvels at the rapidity with which improvements have been effected. The main feature in the culture is the planting out on elevated stages. These stages are so constructed as to hold 4 inches to 4½ inches of soil, and are of a width and elevation which allow the work to be performed comfortably. The houses are of a light and cheap construction, with plenty of top and, where circumstances allow, side ventilation. The system of heating is by means of hot water or steam, the pipes being as far as possible laid under the stages.

There is only one method practised for the propagation of the stock, and that is by cuttings; layering is never resorted to in America. Propagation commences in January, and the cuttings are taken from the flowering plants. At the base of each flower-stem there are generally to be found plenty of side shoots. At intervals the houses are gone over and some of these shoots are removed, only a few being taken from each plant lest it suffer. The cuttings are broken out sideways so as not to break the flattened base of the shoot. The length of the cutting when

HYBRID CYPRIPEDIUM MONARCH.

taken varies from 2 inches to 4 inches; nothing is cut off unless the leaves be very long, when they are shortened. The small leaves at the base are not interfered with. It will thus be seen that the preparation of cuttings is a very simple process.

The cuttings are struck in sharp, clean sand, on a stage similar to those on which the plants are growing, but placed closer to the glass. No bottom-heat is afforded, and the same temperature is maintained as for the flowering plants, perhaps rather higher (55° to 60° by day, and 50° to 55° at night). They are kept on the dry side, and shaded from the sun with newspapers, and in this way root in about four weeks.

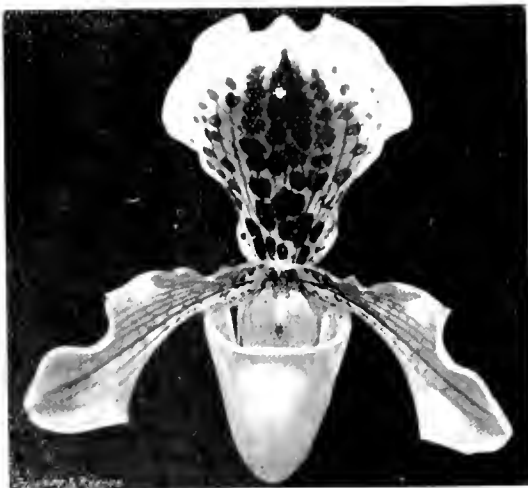

When ready the cuttings are planted out in the houses somewhat closely together, for which purpose one of the flowering stages is cleared off. In a large nursery there will by this time always be found one or several stages which for some reason do not pay well. Such a stage is chosen; all the old soil is cleared out and fresh brought in, a depth of 2 inches being ample. Any light rich soil may be used; if necessary, it is fertilised with artificial manure. A temperature of 50° by day and 45° at night is generally recommended. The beds are kept rather dry. It is, of course, impossible to water without wetting the leaves, and as this is an evil, water must be given seldom and thoroughly. Too much water is likely to produce certain diseases.

The next stage in its cultivation is the planting out in the field. Of late years a tendency has shown itself to do away with the field culture altogether; in fact, in many of the best nurseries the plants never leave the houses. To this indoor culture we shall again refer more fully.

The field in which the Carnations are grown in summer has been richly manured the year before. A rich loam with plenty of natural drainage is best, this being a warm soil, and, therefore, accessible early in the spring, and not likely to become too wet if the summer be rainy. It cannot be too strongly pointed out that too much water is the greatest evil in Carnation culture. The soil may be as dry as powder several inches down, but this does not kill the plants; it only stops the growth; whilst superfluous water produces diseases which cannot be cured.

The planting out near New York commences about the 10th of April, as slight frost does not harm the Carnations in the least. The work is extremely simple; the ground is ploughed, harrowed, and roughly levelled with a rake. The plants, which are lifted in the houses with as little disturbance to the roots as possible, are then placed 10 inches to 12 inches apart both ways. No more land is prepared at one time than can be planted the same day, the idea being to keep the natural moisture in the ground; no watering after planting is then necessary.

After planting, the field does not take much working other than general cleaning. The topping

HYBRID CYPRIPEDIUM MONS. DE CURTE.

* Carnation Growing in America. An essay read before the Kew Gardeners' Mutual Improvement Society by A. E. Cassie.

of the plants is most important. Three topplings are generally required, of which the first is often done in the houses. The aim is to form a short, sturdy plant with many branches near the base. All flower-shoots are, of course, removed. Watering is seldom resorted to in the field, as special arrangements would have to be made, or it would prove too expensive. Much speculation has been devoted to this question, and different systems of irrigation have been proposed, but as far as I know none have proved satisfactory in practice. The summer is often very hot and dry, the night temperature near New York being sometimes for a week together not below 75°. The Carnations under such conditions make no growth, not so much from lack of water as from excess of heat, and if one waters the plants during such a hot period, little benefit accrues. In August and September the nights are cooler, and the plants benefit from a rich dew and progress rapidly even when the days are equally hot and dry.

When indoor culture is adopted, the plants, instead of being placed in the field in spring, are replanted directly in the houses where they are to flower. This system has many advantages: firstly, the perfect control of the water supply which is possible; and secondly, the saving of the autumn shifting, which costs much labour and must necessarily check the plants. One disadvantage is that the old stock must be cleared out of the houses early so as to have them ready for the young plants in May or June, which means the loss of the summer crop. The plants which have been flowering all the winter are by no means exhausted, and when carefully attended to they may flower profusely all the summer, and at times fetch very good prices, as first-class flowers are not produced in the open. Another disadvantage worth mentioning is that the plants by this system will have to remain all the winter in the same soil in which they have been growing during the summer, thus requiring more feeding.

We return to the plants in the field. The housing of these is carried out in August and September. The houses are cleaned thoroughly, whitewashed and painted, and fresh soil is placed on the stages. Good loam mixed with manure the preceding winter or autumn, and supplied with some bone-meal and chemical manure, is generally recommended. It is very important that all natural manures should be thoroughly decayed, as the Carnation does not develop healthily where fresh manure is present in the soil.

When the plants are lifted in the field all the soil is removed from the roots, this operation being best performed with a digging fork, one man lifting the plant whilst another gently shakes the soil off. A few years back the general practice was to shift the plants with a ball, but this method is now entirely abandoned. It does not pay to carry a quantity of old exhausted soil inside. If the houses be well shaded, in the course of a few days the plants look as if they had never been disturbed. In the newly-planted houses great care is taken as to watering and frequent syringing is practised.

The first full crop of flowers is borne about twelve weeks after planting, although many flowers may be cut even a month after. As the plants make their best growth in the field in August and September, late planting has its great advantages, and planting in the latter part of September gives the best crop for Christmas. No good prices can be expected for Carnations before the Chrysanthemums are over.

Attention in winter is simple. When days get shorter all syringing is discontinued, and the water, which is given with the hose, is carefully applied between the rows. The temperature is kept at 50° by day and 45° at night. It is a good plan even in mild weather to keep the fire going and to open the ventilators, as the Carnation likes a dry atmosphere, and fresh air tends to open the flowers well.

Most varieties need some support, which is always given by means of galvanised wire rings placed one over the other, and attached to stakes in the soil. The use of these wire rings is much preferable to tying with strings; it gives a tidier appearance, and, whilst keeping the plants together,

permits of a free natural growth, and, what is an important point, makes the cutting of flowers easy. The wires are, of course, rather more expensive in the first instance, the best costing 27 dols. per 1000, but they last seven to eight years and are extremely easy to put up.

A very important item is the feeding, especially where the plants have been grown on the stages all the summer. To apply liquid manure with a watering-pot would not pay, as it would take too much time. It is generally distributed from a main tank with a steam pump and hose. The stages are frequently top-dressed, a mixture of natural manure, wood ashes and chemical manure being used.

One of the most important operations is the dis-budding, as each flower-stem can only develop one good bloom; all the other buds must be removed early. It is work which, of course, takes much time, but it pays to do it. It does not require any special knowledge or judgment, as it is always the top bud which is the best; in large nurseries girls are often employed for this work.

Anyone who has worked among Carnations will have noticed the bursting of the calyx which so often occurs and makes the flowers unsaleable. Some varieties are more liable to this bursting than others. When selecting seedlings one may at once throw out all those which show short thick buds, as these always burst and are absolutely valueless, no matter how fine the colour may be. But it is not in all cases the structure of the bud which controls the calyx-bursting, and in the good established varieties the percentage of bursting calyces varies greatly from day to day. It is evident that exterior conditions, chiefly temperature and light, have great influence in this respect. I believe that sudden change of temperature is one of the main causes, as also is lack of light. On dark days, and when the houses have been covered with snow for a day or two, almost all the calyces burst. Excess of moisture in the air may also play a part.

In American nurseries the Carnation is often used to replace the Chrysanthemum when these have done flowering, the latter often being grown on similar stages to those used for Carnations. At this time of the year it is, of course, a question of great economic importance to have a continuous crop of flowers from the houses. For this purpose the Carnations are, in the beginning of October, planted in boxes with removable sides, and of a length and depth which allow of their being fitted into the benches. These boxes may be kept in cold frames. When the Chrysanthemums have done their duty they are cleared out and all the soil removed from the stages, and the Carnations are then easily fitted into their place, and in a short time give a fine crop.

The gathering of the flowers is always done some twenty-four hours before they are sent to the city. The transport is generally by railway, as the nurseries are mostly situated far away from their market.

The number of varieties is very large, and is every year being increased through the introduction of many more or less valuable kinds. Few of them stay in cultivation for any length of time, as they soon begin to deteriorate, or when attacked by diseases prove absolutely unable to resist. The deterioration is shown in the decreasing size of the flowers, the bursting of the calyces, and the decrease in general vitality. A good deal has been written in the professional press about the possible causes of the deterioration, but I have never seen anything like a satisfactory explanation. Most experts seem to believe that over-propagation is the main cause. The Carnation is very sensible to changes of environment, climate, and soil. Because a variety does well in one locality, it does not follow that with similar treatment it will prove satisfactory in another.

The Carnation, as are all other cultivated plants, is subject to a great many animal pests and fungoid diseases. Mice, slugs, red spider, and green fly need no mentioning. Of fungoid diseases, black spot, rust, and dry stem rot are most destructive. When taken in time black spot and rust can easily be cured by the application of Bordeaux mixture.

By far the most destructive disease is the dry

stem rot, which every year causes thousands and thousands of dollars' loss to the nurserymen. Most frequently it appears in the houses shortly after the planting in autumn.

The first visible sign of the disease is a fine reddish stripe running along one side of the stem and extending to one or several branches. This marking, the cause of which must evidently be sought in the tissue next to the epidermis, becomes more and more prominent, and the leaves commence to die off till the plant becomes entirely dry and withered, the stem ultimately breaking off at the root-stock. On examination the tissues here are found to be quite destroyed, and only a mass of dry fibres remains; the roots, however, seem unaffected.

The plants may be attacked by this disease both when planted in the houses and when in the field. A few individuals scattered in the beds may become affected and die slowly, or large lots may die off with astonishing rapidity. The disease seems to get better hold when the beds have been lately treated with organic manure; virgin soil fertilised with chemical manure seems to be safe. Again, plants placed a little too deep in the soil are often attacked before the surrounding plants, and such individuals regularly succumb to stem rot even where it does not appear on those properly planted in the same bed. Superfluous moisture also seems to play an important part. I do not say that this simple system results in the very highest development of plant and of flower in themselves.

When cultivating plants in pots one has without doubt far better control of the wants of each individual. Even with as many as a thousand plants in a house one can, to a certain extent, give each a special treatment according to its individual requirements. On the other hand, when one has them all in the same soil they must needs all be treated in the same way; the requirements of each individual cannot be considered. For raising specimen plants or fancy flowers there is no doubt that pots are indispensable, but there is never a large and permanent market for such stock, and it is difficult to make it pay.

As a paying industry I believe the American style of producing cut flowers from plants planted out in the houses and flowered at a low temperature, giving a continuous supply all through the winter, is a decidedly good one. I may add that the same system is practised in the case of Roses, Chrysanthemums, Mignonette, Violets, and, in fact, all florist's flowers except bulbs, and the flowers sold in New York are in no way inferior to those sold here. Most likely the American style will in time be practised also in Europe; in fact, in Southern Germany many large Carnation nurseries are already carried on on American principles.

LILIUM SPECIOSUM IN POTS.

WHERE a greenhouse or conservatory has to be kept gay at all seasons the different forms of this Lily are very useful, as they bloom just at the time when many of the summer occupants of such structures have lost their freshness, and a change is then particularly welcome. With the bulbs of this Lily now arriving from Japan in such good condition this is a good time to pot them for greenhouse decoration, though those that have been kept over from flowering last year should have been potted long ago. These newly-arrived bulbs from Japan can be depended upon to flower well, whether potted singly in 6-inch pots or grouped as fancy dictates in pots of larger size. A mixture of two-thirds loam to one-third leaf-mould or well-decayed manure and sand will suit them well. After potting they should be plunged in ashes or cocoa-nut refuse in the open ground, and, unless the weather is exceptionally severe, no covering will be needed. As the season advances, the pots get full of roots and the flower-buds develop, when occasional doses of liquid manure will be of service. Just before the blossoms expand they should be taken into the greenhouse, where for a month or so they will form a pleasing feature. A good feature of this Lily is that aphides rarely give any trouble, while the scent is not overpowering, as is that of many Lilies.

H. P.

WORKERS AMONG THE FLOWERS.

MR. WILLIAM PAUL.

NO worker in the world of flowers so richly merits a place in our gallery of notable horticulturists as Mr. William Paul, the veteran rosarian of Waltham Cross. He is one of the leading Rose raisers and growers of the present day, and in his beautiful nursery, stretching from the high street of the town to the Great Eastern Railway, masses of Roses—new, old, and seedlings—perfume the air through the summer and early autumn months. It is a lesson of no small value to wander amongst the Roses upon a sunny July day, when the nursery is coloured with the flowers of a hundred kinds, here the rich apricot of W. A. Richardson, there the tender Mme. Hoste, whilst by the edge of grass walks climbing Roses tumble in delightful profusion over pillar and arch.

The work of Mr. William Paul is revealed in all this glorious mass of England's queenly flower, for here is the record of a life well spent for horticulture and in the allied branches of this industry. For upwards of fifty years this renowned rosarian has lived and worked amongst Roses, having commenced business with his father, the late Mr. A. Paul, whom he ultimately succeeded. To enter into details concerning Mr. Paul's life is impossible on this occasion, but we know that some reference to his work will be interesting to readers of *THE GARDEN*.

Mr. Paul's name is closely associated with raising and introducing new plants, not of the Rose only, but of zonal Pelargoniums, Hollyhocks, Phloxes, Camellias, and other flowers; and with regard to fruits and hardy trees and shrubs, collections of unusual interest and importance have been formed at Waltham to add to the cosmopolitan nature of the nurseries. The writer enjoys a visit to Waltham Cross more thoroughly in the fulness of Rose-time than at any other season of the year, and of course this is natural. There is something satisfying in the burdens of odorous blossom. Some new Rose, perhaps, is flowering for the first time, and one learns much about its habit and freedom; or a large group of one of Mr. Paul's own seedlings is in beauty, maybe the delicate lemon Tea Medea, the varied-lined Corinna, the China Rose Duke of York, Queen Mab, or one of the latest of all Tea-scented Roses, Enchantress, which has already entered the gardens of all ardent rosarians.

But we are wandering from the path. It is Mr. Paul himself that must be written of now, and the good work he has accomplished for English gardening through a long and happy life. Of his success as a raiser we have already spoken, but Mr. Paul possesses considerable literary gifts. A list of excellent works has been written by him at various periods of his life. "The Rose Garden" was first published in 1848, and this has reached its ninth edition, evidence of its popularity and usefulness as a treatise upon the history and culture of the flower so entwined around the life of the author. Other books upon horticultural subjects have been written, and various gardening journals

have from time to time received the benefit of his wide experience and mature judgment. Much could be written of the papers read before the Society of Arts, the Royal Society of Literature, the British Association for the Advancement of Science, the Royal Horticultural Society, and kindred institutions, as the subjects are varied, interesting, and instructive, but the principal lectures and papers are embodied in "Contributions to Horticultural Literature, 1843-1892," from his busy pen.

In 1858 the National Rose Society was formed, and that year marked an epoch surely in the history of horticulture in Britain. Among those who joined round the Den of Rochester in starting this interesting association of Rose amateurs and professional growers was our friend. The year after, whilst holding part

and long established in our gardens forming a group of flowers of wonderful colour, and drenching with their perfume the spacious tent.

With such a record it is not surprising to know that Mr. Paul is a Fellow of the Linnean Society, and one of the oldest Fellows of the R.H.S., besides a member of many other associations at home and abroad.

It is interesting to read in his contributions to horticultural literature an article written to *The Florist* of May, 1869. In those days many flowers were in the hands of men who considered that floricultural beauty was displayed in petals patted upon green boxes at the exhibitions. This was distorting Nature in no undecided fashion, and to write against such a travesty of everything that was beautiful in

the flower was to incur the heavy wrath of the school of florists of that day. In his article called "Floriculture and Millinery," Mr. Paul writes the following words, which may be applied sometimes even in these days of supposed greater refinement in the use of the flowers of garden and field: "We are free to admit that a plant must be tied up, and this is better done neatly and with taste than in a careless or bungling manner. Flowers, too, should be so placed in their stands that they may be well seen, and the colours should be so assorted and arranged that they may enhance rather than detract from the beauty and effect of its neighbour. Thus far we concede, may, consider necessary and commendable. But the flattening of Pansies by pressure to meet the florist's canon that Pansies should be flat, the gumming and brushing of the petals of Pelargoniums, the artificial packing of the petals of Carnations, the building up of Dahlias, the pinning of Hyacinths—all these practices are in our judgment of questionable taste, and of even more questionable honesty. By the use of them we may approach more nearly to the florist's ideal, but we are reaching that ideal by trickery and deception rather than by horticultural skill and honest labour." This is pleasant reading.

We might write more about this great rosarian, but the descriptions of new Roses from time to time in our pages ever remind us of his work. It is our earnest hope that he may be spared many years to labour amongst the flowers which have scored his path through life.

MR. WILLIAM PAUL.

of the original nurseries, he founded the now world-famous establishment in the quiet Hertfordshire town. Those who remember the International Horticultural Exhibition in London in 1866 will recall the glorious Roses from Waltham Cross, flowers which won many prizes for their freshness and beauty. This was probably the most important exhibition of plants, flowers and fruit ever held in these isles, and we shall not easily forget the rare evergreens and plants from Waltham Cross at the special exhibitions at Regent's Park (Royal Botanic Society), the Crystal Palace, and elsewhere, a reputation that has been strengthened by the displays of recent years. The exhibit of pot Roses at the Temple show of the Royal Horticultural Society last year was an instructive representation of the Rose as a pot plant and otherwise, varieties modern

THE ROSE GARDEN.

ROSA RUGOSA.

THIS charming plant has given me so much pleasure and satisfaction in its growth and beauty of late years, that I have often wondered whether its many good qualities were as widely known and appreciated as they deserve. It is, of course, well known to florists, having been introduced very many years ago from the northern portion of Japan, I think. But there is reason to believe that it has never been planted by amateurs nor used to any extent in the adornment of either public or private grounds in this country at least. Amid all the puny and tender hybrids in the boundless

realm of the Rose, what a treasure is this most beautiful and vigorous shrub. With bugs, mildew, insects and fungi of every name and nature on every side, there stands the rugosa, unassailed and unassailable, luxuriant and beautiful in leaf and flower. What a vigorous plant it is with its wealth of leafage, dark green, glossy, crumpled and leathery. What a profuse bloomer, early, late and continuous, scarcely ever without flowers in the growing season. And such attractive Roses as they are: lively rosy-crimson petals, with their abundant bright orange anthers. I scarcely know of a more attractive corolla than that of the rugosa rubra Rose. Mine are large, often 2 inches in diameter. Then, too, what a beauti-

grow anywhere under any conditions. The red globular fruit which sometimes succeeds the flower also adds to the decorative value of the plant. It is said to grow true from the seed contained in these hips or pods, though a better and quicker way to propagate it is by suckers and off-shoots, which are freely produced. What a charming hedge it would make impenetrable by reason of its abundant thorns, and beautiful in leaf, flower and fruit at all times.

This Rose seems to have been introduced into European countries from Japan nearly a hundred years ago. Professor Lindley has an etching of the plant in his "Rosarium Monographia," published eighty years ago, although

original plant undiluted in my garden. If I am correctly informed, the first named hybrid of this kind was produced in this country by my friend Elbert S. Carman, formerly for many years editor of the *Rural New Yorker*. This he named Agnes Emily Carman, in honour of his wife. That is now over twelve years ago. He said it was a cross with Harrison's Yellow as the male parent. Even then he had some sixty or more similar crosses with various Hybrid Perpetuals and Teas. They were a strange progeny in appearance, and he found that very few of the rugosa characteristics were reproduced in any of them. The Carman hybrid was sent out soon afterwards to some extent and elicited considerable praise for

THE ROSE WALK AT WALTHAM CROSS.

ful setting it has, surrounded by a crowded cluster of pointed buds in various stages of maturity, some just bursting through the perianth, with bits of colour here and there, the whole nestling in a close bunch of fresh young leaves. Verily a bonnet in itself is just one blooming sprig of this charming Rose—Nature's arrangement. How much of Nature there is in this decorative shrub—its flowers and buds and its simple, robust habit. I like it the more for this reason: all untouched by the botanical skill of man, and devoid of abnormal features so prevalent in the modern floral world—just a single Rose with five large petals and delightful fragrance. Nature makes it all, and we have only to plant and admire it.

the picture is crudely drawn and far from accurate. Just how long it has been grown in America I do not know, but it is rarely met with even now in the average garden. Who will give its history, with the facts regarding the time and manner of its introduction so far as known? I feel sure that among the many well-informed gardeners and florists reached by THE GARDEN there are those who can give this information.

The species has been found valuable as a subject for crossing with other sorts having less constitutional vigour. There are now, perhaps, some twenty or thirty such hybrids which have been dignified with names and a host of others on-coming. But while conceding the value of these productions to the commercial florist, as a true lover of Nature I must prefer the

awhile. But later accounts of it were less favourable, and now little is heard of it. The next hybrid of this class to achieve name and notice was, I think, Mme. Georges Bruant; this came out the year following, if I mistake not, and it attracted much attention also at first on your side of the water where it was produced. Afterwards came Mrs. Anthony Waterer, a very fragrant red flower, and this was followed by several others; but so far as I know none of these hybrids have ever been grown to any extent, although Mme. Bruant, a pure white semi-double Rose, and the Carman crimson, which is also semi-double, are now listed by our leading growers here. The former is a cross between rugosa alba and the Tea Rose Sombreuil. It has the delicious fragrance of both parents and some of the desirable features

It is in all respects ironclad, and it will

of the rugosa stock. Both ought to prove valuable to growers if as hardy as they seem, because of their greater endurance by reason of being partly double. H. HENDRICKS,
Kingston, New York, U.S.A.

WANTED SOME GOOD DARK COLOURED ROSES.

BECAUSE Hybrid Teas and Tea-scented Roses are popular and deservedly so it appears that raisers are concentrating all their efforts towards increasing the already prodigious collection of these and kindred classes. I think I can safely affirm that a good very dark Rose has not appeared for some years. The various groups, if carefully cross-fertilised, would produce some worthy additions to the at present meagre collection of real dark Roses. Everyone loves a rich dark-coloured Rose, but so many are very disappointing. Either their flowers burn, fade off to purple, or refuse to expand, and in addition most of them are very shy-flowering. We want a Rose with the form of Mrs. W. J. Grant (perhaps a little more double) and the rich intense colour of a Victor Hugo, Xavier Olibo, or Charles Lefebvre. Some are expecting great things from the new Rose Liberty. Unfortunately, Roses that are good under glass do not always behave well outdoors. May we then entreat our raisers at home and abroad—and especially abroad, where their opportunities are so manifold to give this matter careful consideration. It is only reasonable to presume that if chance seedlings gave us what we already possess in this direction, that thoughtful cross-fertilisation will achieve even better results, especially as dark Roses seed so freely.

PHILOMILL.

STANDARD TEA ROSES.

MR. C. J. GRAHAME, who is as a writer on Roses invariably trenchant, may be left to the mercy of that older writer on the subject, Mr. D. T. Fish. But when he tells the readers of THE GARDEN that he has disposed of all his dwarf Teas and grows only standards apparently because dwarf Teas are so tender and subject to injury by frost, for no other reason is given, he naturally startles all those whose faith in dwarf Teas or standards, either for garden purposes or for the production of exhibition flowers, is great. But Mr. Grahame must be assumed to know his own business best, and if he prefers standards to dwarfs, no doubt he can justify his choice. I trust he will give full details of the way in which he protects his numerous standard Teas. He tells us he has 3000. Verily, what a spectacle for the gods all the winter must those standards be if their heads be tied up close and enveloped in Fern, or hay, or straw, or some other covering. When dwarf Teas are grown, nothing is simpler or less offensive to the eye than having them earthed up, for ridges of soil are even more picturesque than are flat areas, and what protection is there artificially furnished that is so efficient as soil, how easily added, how easily removed? Then how plump and fresh is the wood that has thus been buried when it is exposed to the light and air in the spring. What good growths result when the shoots are hard cut back to the submerged and healthy wood. After all, there can be little doubt but that Rose wood, Teas especially, is soft or hard according to the season that has produced it, hot summers producing hard wood, and wet summers soft, sappy wood, and hard winters more commonly follow on cold summers than on wet ones. D.

Lachenalia Nelsonii from Gunton Park. We have received a boxful of noble spikes of this Lachenalia from Mr. Allan with the following note: "These fine spikes of bloom were grown from medium-sized bulbs. The largest bulbs do not produce the finest flowers, but have a tendency to split, producing more foliage and flower-stems, but not so fine individually. Just now we have a very great display of them. For a large conservatory in February that has to be kept bright with flowers this Lachenalia is unsurpassed. It may be grown in pots, baskets, boxes, or pans, and, however grown, is most attractive and pleasing."

CORRESPONDENCE.

ALPINE PRIMULAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I am desirous of growing some of the hardy Primulas on my rockery this year, but I am not quite clear as to the soil they should have. I enclose you a photograph of the portion of the rockery which I think will suit them best; it faces nearly due north and is shaded from mid-day sun. If you can give me a few hints I shall be much obliged. The present soil of the rockery is the best loam I could procure. The rocks are yellow sandstone from Norfolk. I could incorporate peat and sand with the soil if necessary. The following are some of the Primulas I have on order: *Capitata*, *denticulata*, *cashmeriana*, *japonica*, *luteola*, *marginata*, *nivalis*, *rosea*, *Sieboldii* in variety, *sikkimensis*, *viscosa major*, and *verticillata*. In any of the above are not worth growing, will you kindly say so? H. E. MOLYNEUX.

Bulham.

[So far as we can gather from our correspondent's description as well as the photograph, we incline to the opinion that the position is in many respects a good one. Many who set to work to grow these and similar plants too often erroneously assume that because they are alpine, a position not only dry, but one embracing only the merest scrap of soil is the one thing at which to aim. To act on this principle is courting failure. Not only are many alpine great rooters, though of small stature, but they delight to send down their root-fibres to great depths in search of the cool uniform conditions that are so much to them and go so far to make them succeed. We trust, therefore, provision has been made in this case for their needs, and we cannot too strongly emphasise this point. So many small rockeries, by ill-construction become so many veritable death-beds, that we cannot refrain from a word of warning. We have known good soil simply deposited on a bottom as hard as a road, spread out a few inches deep, with a few stones interspersed, regarded as a fitting home for choice alpine that would have been safer—infinity safer—and would have stood greater chances of success had they been planted on an ordinary level soil bed. It is not so much a question of the quality of the loam as the amount of it at disposal and the position. Deep fissures or crevices are frequently more suitable than more ample superficial space. Indeed, it should be borne in mind that a niche 18 inches deep and perhaps only 9 inches across would accommodate several little tufts of any of the Primulas of the *viscosa* group or nearly allied forms, and by planting tightly against the sides of the stones, that one essential to success is conceded at the very outset.

The soil may be composed chiefly of loam, with an admixture of clippings of sandstone, grit, and charcoal. If manure is employed, it should be old, so that it will readily pass a ½-inch sieve. Peat is not at all necessary for any of the Primulas of our acquaintance. Taking your list in order: *P. capitata* should be planted in the above mixture without manure, and in a cool spot where a stone block would afford shelter. *P. denticulata* and *P. cashmeriana* require similar care, and thrive best in a deep bed of rich soil, the strong fleshy roots descending quite 2 feet; give partial shade and moisture freely in the growing season. *P. japonica* is never truly happy unless its toes are in water, or, what is next best, some shade and a strong moisture-holding and rich soil. In the former position we have had its giant rosettes of leaves 2½ feet across, and whorls of crimson blossoms in proportion. *P. luteola* is a lover of rich loam with plenty of grit. *P. marginata* often planted in open spots is far happier when snugly nesting at the base of a stone block, while *P. nivalis*, assuming *P. viscosa nivalis* is the intended plant—and *P. viscosa major* will be happy in similar places. *P. rosea* is a moisture-loving species, but its success with much moisture in England is quite conditional. Some of the grandest clumps we have seen were grown in constant shade, that of a 10-feet wall, and in deep,

very sandy soil, liberally dressed with old cow manure. Plants in quite a wet position have failed to reach one-third the size. It is easy to grow and vigorous. *P. Sieboldii* may be treated in exactly the same way, only it should be moved when too crowded. With liberal treatment these attain a diameter of 18 inches and are superb. *P. sikkimensis* must be regarded as a semi-bog plant and a biennial. It may not always be strictly the latter, but it must be this if you wish to see a spike worthy of the lovely class it represents. *P. verticillata* is an Abyssinian species, and too tender for the outside garden. It will be necessary to raise *P. capitata* from seeds to keep up a succession of flowering plants. We would also suggest raising from seed such as *P. denticulata*, *cashmeriana*, *japonica*, and *rosea*, particularly to enable you another year—or even this season if the plants are large enough—to plant small colonies of each rather than solitary examples. The plants should be secured without further loss of time.]

PROPAGATING POLYGONUM BALD-SCHUANCICUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I have been interested in this charming plant since the day some two or three years ago when I first saw it flowering so grandly and profusely in the herbaceous garden at Kew. After reading the note on page 89 of THE GARDEN and the quotation from *Le Jardin* concerning its propagation, I am led to suggest the following: I notice it is suggested in *Le Jardin* to take the eyes for propagating after the manner of Vine eyes. In this species of Polygonum, however, many of the eyes or lateral buds do not remain dormant, as in the Vine, but spring into lateral growth quite freely, such growth resulting in breaks of 1 inch to 3 inches long. Now, if the single eye or bud of this plant will, as in the Vine, both emit root and growth when detached, it would appear feasible that the young shoots to which I refer, if taken from the parent stem with the old-fashioned heel attached, would root in even greater proportion than the older and certainly more wiry wood. This wiriness of stem is a point of great difference as compared with the Vine eye, usually of a prominent and well-matured nature, quite apart from the material support which the eye must receive from the wood itself. In the Polygonum there is no such store of elaborated sap to fall back upon. Still, if the stems root at all when detached, as is apparent by the note referred to, it is more than likely in our own climate that success may be obtained by layering the stems after the method of the Lapageria, either by the ordinary method of layering, or taking out a small V-shaped niche on the inner side of the stem quite close to and a little below the joint. By placing a few boards lengthwise, and filling in 6 inches deep of sand or this and cocoa-nut fibre in equal parts, the rooting would be quicker than in the much colder soil. A spare light or some squares of glass should also be employed for throwing off wet and for other obvious reasons. For choice I would prefer September for the operation either by cuttings or layers, yet in so exceptional a case there is no reason for not doing the same now, and also for treating the stems as in the French case. In this latter, the time selected would also appear to have been late autumn or winter, so that little time is lost. A simpler plan for those having good plants, at least for the time being, would be to train the stems thinly against a warm wall and endeavour to obtain good seeds: even if by fertilising the labour would be well repaid. The plant is such a charming addition to good climbers, that no effort should be spared to secure the supplies for which many owners of gardens are only now patiently waiting.

Hampton Hill.

E. H. JENKINS.

EARLY FLOWERS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, A box of flowers from the garden at Wisley is, I think, worth sending you on account of the early frises. We treated some of the plants to a cold frame, which was fortunate with the late

weather. Iris Vartani, I. Histrion, I. histrioides, I. Danfordiae, I. alata, I. Bakeriana. The snow has left its mark on Oakwood, big boughs of Rhododendrons having been broken off. The worst sufferers are a large fine Tree Ivy and a tall double Furze, which are smashed. G. F. WILSON.

[With this note came some charming flowers, among them the finest-coloured *Anemone blanda* we ever saw; also *Hepaticas*, *Lent Hellebores*, white and red, *Spring Snowflake*, *Violets* and *Crocus Imperati*. But in this delightful gathering of early gems those of the greatest interest and beauty are the *Irises*: the large and beautifully fringed *I. alata* of the Algerian hills, the clear-cut yellow *Danfordiae*, the well-coloured and marked *Histrion* and *histrioides*, and for colouring most remarkable of all, *I. Bakeriana*, in which the fall ends in a thick wedge of velvet-like purple-blue, so dark that at first it looks black, and all the blacker because it is approached by a region of white ground spotted and pencilled with the same.—Eds.]

A FLORAL CLOCK.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—During the coming season I desire to make a "floral clock," i.e., to plant a collection of flowers which open at various times from morning to night, thus giving an approximate indication of the time. Will you kindly give me a list of suitable plants? Keighley. A. K.

[Perhaps some reader of THE GARDEN can furnish such a list. Eds.]

LOBELIA TENUIOR.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Can any reader of THE GARDEN help me to get some seed of *Lobelia tenuior*? I saw two plants of it in the Cambridge Botanic Gardens last summer, and have never seen a more lovely thing. I have applied to our best seedsmen, and so far without result; but it may be that someone may see this who knows where seed may be got. Mr. Lynch writes me that the plant has been grown for some twenty years, and this being so, it seems strange it should be practically unknown, as it would seem to be. B. DICKINSON WEBSTER.

Newton Abbot.

MISTLETOE FROM SEED.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—I shall be pleased to send "Medway" seeds from a growing Mistletoe either next month or when he pleases later. About one in ten of ripe seeds start very freely on the under side of a branch glued on by its own viscosity without injuring the bark of the branch. But when started the seed should be wired on, as I have found, and have also heard from another source that the young plants are very liable to being blown off during the second year before they have got sufficient hold. If he will send his address to the editor it will be posted to me.

Ambleside.

H. B.

ROMNEYA COULTERI.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—This lovely plant, at any rate down in South Devon, seems a most capricious bloomer. I have been watching four or five plants in neighbours' gardens and one in my own to find out what the plant requires to be a success. My own plant, now 4 feet through, makes luxuriant growth, and does everything one would expect but flower. It seems to be quite indifferent to cold; in fact, it has not shed all its leaves this winter, and we have had rather more frost than usual. It never seems to flag for water in summer, which, being a native of California, one would not of course expect it to. It does not seem to be particular about soil, or at any rate it makes equally clean growth in my light soil among rocks and in a neighbour's garden on the level where the soil is heavy. Apparently it is indifferent to food, for a plant heavily watered with manure two consecutive years bloomed well the first year and had one single

flower the next. What does it want? Perhaps some of your readers will give us their views. When I bought my plant I was assured a position on rockwork in full sun was all that was needed, but it seems there is something more wanted. The only thing I have left to try is the removal of last year's wood, and that I shall try so soon as the new growth shows, which may be any time now, I suppose. Hitherto I have kept the one-year-old wood, and only removed that of the preceding year. B. DICKINSON WEBSTER.

Newton Abbot.

MUTISIA DECURRENS.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—In reply to "T. J. W." I beg to say that I have had this plant for six or seven years, doing well and flowering every year. It is growing against a south wall with a projecting balcony above it, and to this I attribute its success, as it is kept dry in winter and spring, and thus neither frost nor wet hurts it. This overhead shelter is, I feel sure, valuable for many tender plants. In a similar situation *Daphne indica* has been growing for many years, flowering beautifully every winter. The *Mutisia* runs much underground and sends up suckers freely, but I find these very hard to remove safely. A. R. W.

Parkston, Dorset.

WINTER ACONITES NOT FLOWERING.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Can you explain this? I have plenty in full leaf, but very few flowers. It was so last year also. Richmond, Surrey. W. P.

[We have heard other cases of *Winter Aconites* refusing to flower, though in most places they flower abundantly every year. It may be that the roots are overcrowded and require replanting. You do not say what is the nature of your soil.—Eds.]

GARDENING OF THE WEEK.

KITCHEN GARDEN.

ROUTINE WORK.

MUCH of the work advised during the past two weeks will have been delayed owing to the heavy snow-fall and frost, and the forcing department will have been in greater demand to eke out the daily vegetable supply. Such seasons as we are passing through show the value of winter roots such as *Salsafy*, *Scorzenera*, and *Celeriac*, as these when stored are got at readily, and even in mild winters, with plenty of green vegetables at command, they give a welcome change. The snow will have preserved choice vegetables, such as winter *Broccoli*, but it is well to lift and shelter any that have heads, as frost soon affects the flavour, and in the case of green vegetables it will be well when frozen through to cut them a day before they will be required, and thaw slowly indoors previous to using. Forcing pits will need replenishing to keep up constant supplies, but this will be done more readily if some long litter is placed over the forcing roots in the open, as in most cases the latter are lifted early in the season and laid in thickly for use as needed. Much during this weather may be done in the way of clearing up odd corners removing rubbish, and preparing for spring cropping by writing labels, sifting soils and preparing manures, also affording protection to vegetables needing it.

SPRING ONIONS.

As soon as the ground is in condition for sowing there should be no delay in getting in the seed. I am aware that in some seasons sowing is at times delayed well into March, but I am in favour of early sowing in light well-drained soils, as the plants will stand more cold at the start than many imagine. There are several advantages in sowing at an early date, as the plant gets a longer season's growth, and I find that the earlier sown plants are

less troubled by the dreaded grub or fly than when later sown. As regards the sowing and varieties, few words are needed. The plants need a rich, and at the same time a well-worked soil, trodden firm on the surface before sowing. Where there is the least fear of maggot, now is a good time to prevent its ravages, and a good dressing of lime or soot will be advantageous, though it is only fair to add that the soil would have been better if prepared some time in advance of sowing. It is well to give the seed as good a chance as possible by not sowing on land that has grown the same crop for some time. Wood ashes form a valuable aid in poor land. Failing this, burnt refuse may be used; this used freely in the drills will keep the seedlings healthy. It is not necessary to use stable manure in land that was well manured for a previous crop, but one may rely on the above aids and feeding freely during growth with fertilisers. The latter may with advantage be sown in the drills with wood ashes or soot.

Varieties are becoming numerous, and such kinds as *Carter's Record*, *Ailsa Craig*, *Excelsior*, and *Sutton's Improved Reading* are all excellent and give very fine bulbs, whilst for keeping purposes the *Bedfordshire Champion* is one of the best.

Syon Gardens, Brentford. G. WYTHES.

INDOOR GARDEN.

CALADIUMS.

THESE should now be shaken free from the dry soil in which they have been wintered and potted up in small pots, varying, of course, with the size of the corm. The soil used at this potting should not contain any manure, this being reserved for the next potting, when the roots are active and able to assimilate extra food. For the present a good mixture will consist of equal parts peat, fibrous loam, and leaf-mould. With this mix in silver sand freely and let the base of the corm rest on a good sprinkling of the same material. After potting, place the pots in a temperature of from 60 to 65°. Keep the pots and the surface on which they stand moistened freely with the syringe, but do not water the soil until growth commences, as if fairly moist when used for potting, it should retain sufficient moisture to carry them through to the growing stage. If it is thought necessary to increase the stock, this may be done by dividing the corms carefully into pieces, each of which contains at least one fairly prominent bud. These pieces must not be potted right away, as bleeding in moist soil would be sure to induce decay; they should be sprinkled with dry powdered charcoal and flowers of sulphur and placed on a dry shelf in a warm house until the cut surfaces have quite dried up and hardened.

TUBEROUS BEGONIAS.

The pots of these should be looked over, and any that show signs of starting should be shaken out at once and repotted in the pots in which they are to flower, this being a safer plan than shifting them on into bigger pots later. A good mixture for these consists of two parts of loam, one part each of leaf-mould and decayed cow manure, using sand freely. Keep the tubers well beneath the surface, so that the collar of the plant is covered with soil when the shoots push through. Water carefully to begin with, and fumigate the house once or twice with XL. All soon after the first leaves show to get rid of thrips which may be lying dormant now. A house with a temperature of 50° by night will suit these *Begonias* well, and it is not necessary that it should have the south aspect so needful to many things.

SOWING SEEDS.

The time has now come when there are many seeds that require to be sown. Among others are *Greivilleas*, *Acacia lophantha*, *Fuchsia*, *Celosia*, *Coleus*, *Myrsiphyllum*, and *Cyclamen*: the latter only if we cannot afford to wait until August for plants raised then, which will certainly be best, though a season is lost in flowering them. As a rule the conditions and time for sowing are printed on the seed-packet, but a word of caution may be necessary, for I find it better to delay sowing as a general rule for a week or two later than the dates given. Another thing is to avoid the mistake of

sowing all seeds in strong heat. This has the effect of checking rather than forwarding the vegetation of seeds of those plants which require cool treatment when growing, and only seeds of warm house plants should be sown in strong heat. One of the most useful stove plants of which to sow seeds now is *Cherodendron fallax*. I mention this particularly, as seedlings are better than cuttings, and, again, because it often fails to germinate when sown singly in small pots; while, if sown thickly in pans, the seeds germinate with great freedom, and the young plants may then be potted off singly while quite small.

J. C. TALLACK.
Shipley Hall Gardens, Derby.

FRUIT GARDEN.

PEACH TREES OUTSIDE.

PRUNING, nailing, and tying being deferred to the last, so as to retard as far as possible the opening of the flowers, cannot much longer be continued. The work must be completed before the buds have swollen. Prune out wood that bore fruit last season, strong gross shoots of last year, very weak unripened wood, also old snags, leaving the tree furnished throughout with medium-sized well-ripened wood, not too close in any part, and less so amongst the more extended branches. There is some difference of opinion whether fan-trained Peach trees should have a centre leading shoot or not. In my opinion they should not. The centre shoots grow too strong to be fruitful, and they draw away the sap from the lower side branches, making them too weak to bear fine fruit. The central leading shoot of trees with two or three years' growth from the time of being worked and planted last autumn may be cut out. Begin nailing the largest main branches, fixing them at the same angle on each side as far as possible, so that both sides appear to balance.

If dressing of the trees has not already been finished, take the earliest opportunity of syringing thoroughly with a proved reliable insecticide for the purpose of killing green or black aphides, either of which is sure to be present in crevices of old bark or other hiding-place ready to attack young leaves. By the time the flowers begin to open have coverings ready for use on frosty nights.

In growing Peaches out of doors it is important to avoid overcrowding of the wood. Keep the foliage clean and healthy throughout the growing season. Good foliage results in ripened wood, and in the season healthy flowers.

STRAWBERRY BEDS.

Carefully look round each plant and remove runners. Afterwards, if manure was not applied in the form of a top-dressing at that time, let it be done forthwith. Give a liberal layer of farmyard manure and feed the plants, as this serves as a mulching, which is equally valuable.

ALPINE STRAWBERRIES

are very useful for supplying fruit after the large varieties are past. This section has been much improved of late years by the introduction of varieties bearing fair-sized fruit. Now is a suitable time to plant. Select from existing beds young, strong, well-rooted crowns, plant them in rich, deeply-cultivated ground, putting the plants 1 foot apart in the row and 2 feet between the rows. Also the plants may be raised from seed sown at this time and brought on in gentle heat. Prick off when large enough and plant out when strong and well hardened off.

LOOKING OVER FRUIT IN THE FRUIT ROOM.

Take advantage in time of bad weather to look over Apples and Pears in the fruit room to pick out the decaying fruit. To prolong the season as far as possible, use first those kinds that show signs of decay.

Good free-bearing fruits are, of Apples, dessert: Wyken Pippin, Adams' Pearmain, Cockle Pippin, Court pendu Plat, D'Arcy Spice, Lord Burghley, and Sturmer Pippin. For kitchen use: Lane's Prince Albert, Wellington, Dutch Mignonne, Rymer, Mere de Menage, and Round Winter Non-such. Pears for dessert: Josephine de Malines, Knight's Monarch, and Bergamotte d'Esperen. For stewing: Yverland and Uvedale's St. Germain.

The Gardens, Hatfield House. G. NORMAN.

SOCIETIES.

NOTES FROM THE SCIENTIFIC COMMITTEE (R.I.S.). FEBRUARY 13.

ELM BARK WITH LARVAE.

MR. W. BROOKS, of Weston-super-Mare, forwarded a piece of bark of an English Elm tree, with the following observations: "The Elm trees are attacked by an insect which is destroying them. Some of the trees are fine, nearly 100 feet high, and in their prime; others are smaller. The larger trees are attacked more especially on the north side, but the smaller all around the stem from bottom to top. One of the largest trees shed all its leaves in August, and it looks as if the whole of the trees will die."

Mr. McLachlan sent the following report: "The Elms are attacked by the larvae of a beetle. No perfect beetles are to be found in the bark sent, but there are numerous larvae, each in a small cell, in which it will undergo its transformations. So far as can be judged from these larvae, they are those of *Scolytus destructor*, so common in many places. In order to destroy them it was suggested, more than forty years ago, by the late Capt. C. J. Cox (who probably took his idea from the French), that all the old outer bark be pared off by a spokeshave or some similar instrument (the scrapings being of course collected and burnt), taking care not to injure the inner bark and wood. Dressings of dilute petroleum, repeated at intervals in dry weather, might also be of service. But the subject opens up a wider question—viz., whether the beetle is the cause of the condition of the trees, or only steps in where these latter are in a moribund state from some other cause. The writer of these remarks is inclined to think the beetles come as scavengers. At any rate in the case of tall old trees, probably already 'stag-horned,' it is practically useless to employ remedial measures, and the best thing is to cut them down and burn them, or at any rate cut them away at once from the vicinity of trees not already attacked. The bark of such old trees is usually riddled by the larvae from base to top. When the trees are younger and less tall, remedial measures, such as those suggested, might be tried. Even supposing the trees to be in an unhealthy state from some other cause, the attacks of the beetle must aggravate that state and hasten decay, and if these attacks could be lessened or averted, there might be a chance of the trees recovering from the other conditions whatever they may be. But as a rule disease or decay have already proceeded too far before being discovered."

FERN ROOTS ATTACKED BY GRUBS.

MR. BURT, of The Gardens, Caeuwood Towers, Highgate, sent a specimen of soil and grubs with the rhizomes of *Adiantum cuneatum*. Mr. Hudson observed that he was not unfamiliar with them. The specimen was forwarded to Mr. McLachlan, who reports as follows: "The grubs at the roots of *Adiantum* are those of a species of weevil, probably *Sitona*, but I cannot commit myself to anything more precise without seeing the perfect insects. I should think the best thing to do now would be to turn out the plants from the pots, shake the old soil from the roots, and repot in clean earth, taking care to burn all the old with the grubs. When the foliage shows signs of being attacked go over the pots at night, turn each pot gently on its side, and shake the foliage over a sheet of paper. By this means multitudes of the perfect insects may be collected and destroyed, and the deposition of eggs prevented."

OROBANCHE ON PELARGONIUM.

A plant in flower was shown by Frances M. Cooper, Forest Road Gardens, Wokingham, described as having "established itself in a pot of *Geranium*." The latter at first showed no sign of diminished vigour; but now the specimen has come into bloom its host-plant seems to be weakly and its leaves are turning yellow. The plant does not seem quite like any wild species. The *Orobanchae* was of a purple colour throughout, but not agreeing closely with any true British species.

SHROPSHIRE HORTICULTURAL SOCIETY. ANNUAL MEETING.

THE annual meeting was held recently in Shrewsbury, when a large number of members were present. The Mayor (Mr. R. S. Hughes) was in the chair, and he congratulated the members on the extraordinary success which attended the society's last show, and on the fact that the receipts for the past year exceeded any previous record by considerably over £200.

Mr. H. W. Nanton (one of the hon. secretaries) presented the annual report of the committee, which is as follows: "It appears to be the general opinion that the horticultural display in the Quarry, on August 24 last, was the finest and best ever seen there, and it is satisfactory to report that the attendance was the largest on record, and that the receipts on that day and the profits on the year exceeded all previous returns. The collections of Grapes, which included exhibits from many of the best known Vine growers in the kingdom, were undoubtedly a success, and the results should encourage the society to continue their experiment of introducing novelties in future exhibitions. It is proposed this year to offer large prizes for collections of British-grown fruit, which will probably attract a large number of competitors, and which, in consequence of the great variety in form and colour of the exhibits, will, no doubt, meet with general appreciation. Our hearty thanks are due to our president (the Rev. T. M. Bulkeley-Owen), not only for his acceptance of that office, but for his long-continued co-operation with the society and the interest he has always taken in its success. The report would be incomplete if it failed to express the very deep regret felt by the committee on hearing a few weeks since of the death of Mr. Outram, one of their judges. He had acted in that capacity for many years, and the society had benefited not only from the careful manner in which he discharged his judicial duties, but also from his ready-given advice in all matters, and they were numerous, on which he was consulted by the committee."

The assistant treasurer presented the statement of accounts, and pointed out that the total receipts for 1899 amounted to £4739 10s. 11d. The profit on the summer show amounted to £1050 13s. 5d. The balance in the bankers' hands on December 31, 1898, amounted to £1808 15s. 3d., and on December 31, 1899, to £2149 9s. 10d. The actual receipts on two days of the summer show (excluding subscriptions) amounted to £4154 3s. 2d., and the actual payments to £2648 13s. 7d. The society's total receipts for twenty-five years amounted to £65,197 10s. 8d. The donations and gifts made by the society amounted to £5840 10s. 6d., and, in addition to the balance of £2149 9s. 10d. in the bank, the society owns land situate between the Quarry and the Friar's Bridge (purchased from the town), which cost £5500. The prize money given during the year amounted to £1059 17s. 3d.

BRISTOL GARDENERS' ASSOCIATION.

THE fortnightly meeting was held at St. John's Parish Room on Thursday, 22nd ult. Mr. Chas. Lock presided over a good attendance. The paper was supplied by Mr. A. Moore-Sara, of Elmside, Stoke Bishop, on "The Pollen Grain and its Functions." With the help of black-board diagrams he made the subject very interesting, tracing what is known of the sexuality of flowers from the time of Herodotus down to the 17th century, when, in 1676, Dr. Grew, in a book on plant anatomy, laid down in definite terms the law of vegetative impregnation, accepted by botanists to-day, and in a greater or less degree understood by all present-day gardeners. Dealing in detail with the subject, he described the formation of the pollen, some of the many methods of distribution, and the processes through which it had to pass until fertilisation was complete. A short discussion followed, chiefly on the advisability of forming a botany class in connection with the association.

HAMPSTEAD HEATH PROTECTION SOCIETY.

THE following is the report of the past year of this excellent society:

The committee have pleasure in submitting their third annual report, together with a statement of accounts to December 31, 1899.

Since the date of the last meeting the committee have been actively engaged in promoting the objects of the society, and are glad to find that the interest of the public in their work has been sustained.

It will be remembered that your committee have all along advocated the appointment of a ranger to preserve the amenities of the Heath, and they desire to record their appreciation of the assistance they have received from the Metropolitan Public Gardens Association to this end. At a meeting of that association on January 4, Lord Meath in the chair, the following resolution was passed unanimously: "That this association approach the London County Council asking that body to appoint some responsible and experienced person to superintend all work carried out on Hampstead Heath, and asking that such work shall be for the preservation of the natural beauties of the Heath, its Gorse, trees, shrubs and ponds, and the views from the same in accordance with the provisions of the Hampstead Heath Act of 1871."

This action resulted in the appointment in the month of March, 1899, by the London County Council, of a resident superintendent ranger (Mr. George Palmer) for Golder's Hill, Hampstead Heath, and Parliament Hill Fields, and the anticipations formed by your committee of the benefits that would result from such an appointment have been fully realised up to the present time.

Your committee have been in active correspondence with the London County Council during the year on various subjects, among which may be mentioned the damage done to Furze, Ivy, and shrubs by the sheep which are allowed to graze on certain parts of the Heath.

The council have so far met the views of your committee by passing a resolution to restrict the area upon which the sheep may graze to the lower portion of the east Heath, where they are less likely to do damage.

The committee trust that the areas from which vegetation has disappeared will be temporarily fenced out where necessary, and measures taken for renewing the natural vegetation, such as grass, Fern, Broom and Gorse.

Another point to which your committee have asked the attention of the council is the shooting of cinders on the Heath, and they have expressed their strong opinion that if any cinders must be brought on to the Heath for the repair of roads, they should not be shot on the grass, but kept as far as possible out of sight.

The committee have also asked the council whether the time has not arrived for allowing the public at least partial access to the grass enclosures near the Hampstead Heath Railway Station, but the council consider that nothing need be done in this direction at present.

With regard to the over-planting of trees which has been referred to in previous reports, your committee are still pressing the council to take action, and hope that when the matter comes again before the council, regard will be had to the often-expressed wish of the public and of the society. One of the members of the council, in whose energy and discretion the committee have full confidence, has put himself in communication with the chairman of the Parks and Open Spaces Committee, and will, as soon as convenient opportunity arises, take care that the views of the society on the question of the over-planting, with special reference to the trees on the north-east side of the Spaniard's Road, are again brought fully before the council.

The committee have co-operated with the Northern Heights Footpath Association in their suggestion to the London County Council to purchase the small strips of ground adjoining the Heath at North End, which have been marked out by small posts as private property.

The committee are gratified by the interest shown by the chairman and vice-chairman of the Parks Committee in visiting the Heath and conferring with some members of the society as to the preservation of the small rain-pools and other picturesque features of the Western Heath.

SHIRLEY GARDENERS' SOCIETY.

An interesting meeting was held recently, when Mr. E. T. Melton, of Hartley College, Southampton, gave an interesting lecture upon "The Composition of Manures and their Applications to Various Soils," illustrated by lantern slides and diagrams. Several plants were exhibited at the meeting. The chair was taken in the absence of the president by Mr. B. Ludhams. The secretary of this prosperous society is Mr. H. J. Hobbs.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

The annual meeting of this society will take place at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday, March 12, at 8 p.m. Mr. S. T. Wright, superintendent of the Royal Horticultural Society's Gardens, Chiswick, has kindly consented to preside.

NEW AND RARE PLANTS.

IRIS STENOPHYLLA.

THIS is a very beautiful bulbous Iris, one of the early-flowering group, and quite as interesting as any other species in bloom about this time. The flower is as large as that of *I. alata* and richly coloured; the standards a full deep purple, relieved with a lighter colour at the base, spotted purple, and an orange line runs into the throat. We shall give a further description, and also an illustration of this charming flower. A pamphlet was shown by Messrs. Wallace and Co., of Colchester, at the last meeting of the Royal Horticultural Society, and given a first-class certificate.

PRIMULA KEWENSIS.

An interesting and important new garden plant, which has been flowering at Kew since October of last year. It is a hybrid between *P. floribunda* and *P. verticillata*, and possesses the best attributes of both parents. The plants bloom with wonderful freedom, being covered with a mass of rich yellow flowers which remind one strongly of those of *P. floribunda*, but are larger individually. It is a bright, handsome and welcome addition to the list of indoor Primulas. Several plants came from the Royal Gardens, Kew, to the last meeting of the Royal Horticultural Society. First-class certificate.

AGAPETES BUNIFOLIA.

This is a very old garden plant, but so rare that it comes to us now as almost a novelty. It is a native of Northern India, evergreen, and its leaves remind one in texture and form of those of the Box. The bright red flowers appear on the ripened growths of the previous year, and the tubular corolla, about 1 inch in length, has five pointed tubes, followed by milky white fruits. It requires much the same treatment as the greenhouse Azalea, but, as already mentioned, is very rare now-a-days. This is a pity. These beautiful hard-wooded plants are too interesting to entirely neglect. Nuttall first found this species on the Duphla Hills, between Bhotan and Assam, at an elevation of about 3000 feet. Mr. J. T. Bennett Poe showed a remarkably well-flowered specimen at the last meeting of the Royal Horticultural Society, and was given an award of merit.

CAMELLIA GENERAL HECTOR MACDONALD.

This is another handsome addition to the list of new Camellias. This variety reminds one of *reticulata*, so large and imposing is the rich red flower. It is a welcome novelty. Award of merit at Royal Horticultural Society's last meeting. Shown by Messrs. Sander & Co., St. Albans.

LELIA EDISSA.

This is a cross between *L. anceps* and *L. purpurata* and is a remarkable plant, showing the intermediate characters of the two groups. The sepals are 3 inches long and rosy lilac, the petals nearly 2 inches broad, and similar in colour to the sepals. The lip is upwards of an inch broad, bright crimson, veined with a darker shade of colour and margined with rose on the front lobe. The side lobes are rose, shading to yellow, suffused with purple and lined with a darker tone of purple through the base and throat. The three-flowered raceme is produced on a scape resembling *Lelia anceps*. First-class certificate, Royal Horticultural Society's last

meeting. Shown by Messrs. J. Veitch & Sons, by whom it was raised.

CATTLEYA TRIANE (WEST BANK HOUSE VARIETY).

This is a charming form with finely-balanced, deep rosy-lilac sepals and petals. The lip is rich crimson-purple in front, margined with rose, a white area being in front of the orange disc. The side lobes rose, lined with white at the base. Shown by Mr. J. Leeman, West Bank House, Heaton, Mersey, Royal Horticultural Society's last meeting, and given an award of merit.

ZYGOPETALUM BALLII.

This is one of the most beautiful and distinct of the Zygopetalums. The sepals are 2 inches long and rosy purple, margined with white. The petals as long as the sepals, $\frac{1}{2}$ inch broad, white, spotted with purple on the upper half, suffused with the same colour at the base, and margined with white. The lip is $1\frac{1}{2}$ inches broad and $1\frac{1}{2}$ inches long. There is a margin of white nearly $\frac{1}{2}$ inch broad. The basal area is suffused with purple. There are also some violet-purple lines on the disc. Royal Horticultural Society award of merit last meeting. From Mr. G. S. Ball, Ashford, Wilmslow, Cheshire.

ODONTOGLOSSUM ADRIANE VAR. LORD ROBERTS.

This is one of the most beautiful of the Hummelian-*crispum* hybrids. The sepals are about $\frac{1}{2}$ inch broad, pale yellow, blotched with purple in the centre and on the basal area. The ground colour of the petals is lighter than the sepals, and covered over the central area with smaller purple-spottings. The broad lip is creamy white, with some large purple spottings in the centre and smaller markings on the basal area. Award of merit, Royal Horticultural Society's last meeting. From Mr. W. Thomson, Stone, Stafford.

ODONTOGLOSSUM LOOCHREISTENSE.

A natural hybrid between *O. triumphans* and *O. crispum*. The sepals are yellow, with some purple suffusion and bright brown spottings, more numerous on the upper than the lower ones. The petals are brighter than the sepals, with two or three large brown spots in the centre and numerous smaller ones on the basal area. The flower is of fine shape and substance, and upwards of 3 inches in diameter. It resembles a glorified form of *O. excellens* with the lip of *O. crispum*. It is by far the finest of this particular cross that we have seen, and with increased strength should be given to letter advantage. The plant exhibited carried a single flower on the raceme. Shown by Mr. W. Thomson, Stone, Stafford (gardener, Mr. W. Stevens), and given an award of merit, Royal Horticultural Society's last meeting.

LAW.

AN INTERESTING SEED CASE.

IN the City of London Court on Friday, before Mr. G. Pitt-Lewis, Q.C., Deputy Judge, an action was brought by Messrs. Bowcott and Watkins, seed merchants, 10, Floral Street, Covent Garden, against Mr. R. W. Gardner, Princess Road, Victoria Road, Roufford, to recover the sum of £6 15s., damages for breach of contract in respect of certain Swede Turnip seed. Mr. W. R. Hison, plaintiffs' solicitor, said that the plaintiffs bought the seed of the defendant on the understanding that it was 1898 or new seed. The plaintiffs, upon applying the ordinary test which was well known to the trade, found that the productiveness of the seed only yielded 60 per cent., and not 98 per cent. The plaintiffs had paid for the seed, and now that they found that it would not answer their purpose they were asking for the return of their money or for damages for breach of contract. Mr. Charles Butler, defendant's solicitor, said that the parties were well known to each other, for the defendant had been in the plaintiffs' service for twenty years. He had sold them the seed in question the day after he had purchased it. They retained it for two months before they found any fault with it. The practice was to test seed within a week. The plaintiffs had dealt with the seed before rejecting it. Mr. Watkins, plaintiffs' manager, was called and spoke to having purchased eight or ten bushels of the seed in question at 18s. 6d. per bushel. He understood he was buying new seed, and that meant that it was the previous year's seed. They usually tested seed immediately it came into their warehouse. The seed in question was tested on tannel and then on soil. The germinating power of seed which was two years old would be about 85 per cent., and perhaps more. It depended upon what care was taken of it. The percentage of productiveness depended to some extent upon how seed was tested. Martin, who was employed by the plaintiffs, deposed to having tested the seed in question. Mr. Butler explained that the plaintiffs should have rejected the seed

within a reasonable time, and that they did not do. The defendant was called, and said that he bought the seed in question for 18s. 6d. a bushel. Knowing that the plaintiffs wanted some of the same sort he offered it to them and they bought it, his profit being £1 on the transaction. Two months after the deal, when he ceased to think about it, the plaintiffs wrote and told him that the seed did not grow well. If he had been informed in time he could have gone to his sellers and raised the same point. Mr. Paul Ursulas was called to prove that the seed had yielded 90 per cent. The Deputy Judge said he came to the conclusion that there was a warranty that the seed was new seed. The plaintiffs were entitled to damages for the defendant's breach of contract, and he thought they ought to recover two-thirds of the money which they had paid for the seed. There would, therefore, be judgment for the plaintiffs for £2 5s. as damages, with costs of the action, and they would keep the seed.

ANSWERS TO CORRESPONDENTS.

Names of plants. *Solpinae*.—*Primula floribunda*, 1. *E. W.*, 1. *Ceterach officinarum*; 2, apparently an immature frond of *Pellaea corallata*; 3, *Nephrodium decumpositum*; 4, *Adiantum fulvum*.

Cyclobothras (H. T.).—Pot the bulbs at once in light well-drained soil and plunge in a cold frame, and in about a month's time plant outside on a warm south border. It all depends on the present condition of the bulbs whether they will be a success or not; if hard and firm, all well, but if shrivelled and dry, the result may not be satisfactory.

Cucumbers in frames (S. F. J.).—Do not attempt to make up a cucumber bed on a large scale until you have good strong plants nearly ready and plenty of fresh stable manure. But you can make up at once a small bed to suit a small frame in which to sow cucumber seed in pots that will produce plants. These may be strong for planting out into a permanent bed in about a month from sowing if you have kept up a good warmth. That is the difficulty with manure beds early in the year, as in cold weather the temperature goes down quickly. Perhaps it would be wiser for you to order plants to be ready to plant out in a hotbed about the middle of March. In the meantime collect stable manure, keep it occasionally turned and mixed, shaking out the longest straw. For a frame of two lights, 8 feet by 6 feet, the hotbed should be 12 inches wider and longer than the frame, and be nearly 3 feet in height when made and trodden firm. It will require a good amount of manure to form such a bed, and even when planted it is needful to place fresh manure as rapidly as it is collected round the bed to keep in the warmth.

GARDENING APPOINTMENTS.

MR. JOHN LOGAN, late gardener to Mr. G. de Belle Ball, Lisson Hill, Swadlow, has been appointed gardener to Mr. W. Woodburn, Hermitage, Rathfarnham.

MR. A. BROWNE, late head gardener to Mr. Pim, Stradbroke Hall, Monkstown, to a similar position in the gardens of Mrs. Henshaw, St. Philips, Milltown, in succession to Mrs. McKay.

MR. A. WARD, Stoke Edith Park, Hereford, gardener to the late Lady Emily Foley for the past seventeen years, and latterly sub-agent, has been appointed head gardener to Mr. F. A. Bevan, Trent Park, New Barnet, in succession to Mr. W. H. Lees, who is, we understand, entering business on his own account.

CATALOGUES RECEIVED.

LAWES, & Co., *James Carter & Co., High Holborn, London.*
FERN SEEDS. *Little & Ballantyne, Carlisle.*
CHRYSANTHEMUMS. *Vilmorin-Andrieux & Cie, 1, Quai de la Marée, Paris.*

[MARCH 10, 1900.

FRUIT GROWING IN THE BRITISH ISLES.

(WITH SPECIAL REFERENCE TO APPLES.)

WE mentioned in *THE GARDEN* of last week (p. 153) that the fruit industry of this country was sufficiently valuable to stimulate a keener interest than is apparently expressed by the trade and private growers of the present day. Horticulturists were rudely awakened to a sense of their opportunities when the famous Apple congress held by the Royal Horticultural Society at Chiswick aroused public interest, and revealed an ignorance of Apple culture incomprehensible in a country capable of producing fruit as ruddy and handsome as the rosiest importations from over the seas.

The national insular conservative spirit dominates in a measure horticulture as severely as its sister, agriculture. We seem loth to leave the path lined out by our forefathers or to attempt to improve upon their ways of culture. But this clinging to the traditions of the past is unreasonable: it is futile to rail against foreign importations into the market unless the British grower presents fruit as luscious to tempt the national palate. A large demand exists for British-grown Apples. A stroll through any of the great market centres reveals the pleasant fact that the best winter Apples from our orchards realise prices not approached by the Apples from abroad.

Quite recently that good Apple Wellington, or Dinnelov's Seedling, was bringing in the handsome return of from 10s. to 12s. a bushel from standard trees, and it requires no intense mathematical perception to know that a few acres of trees would realise a respectable annual income.

We are not standing still, it is true, but progress is slow. Our markets reveal little of the change, for the reason that the grower is apparently slow to move until some incident occurs to arouse him to a sense of his loss in permitting a profitable industry to slip into other hands. Greater facilities for importing fruit mean, of course, severer competition at home, and it is an almost weekly occurrence to find that Apples from far distant lands have been received in England—fresh, wholesome, and possessing their natural good looks—a condition of affairs impossible before the quick mercantile fleets of the present day. We enjoy the home-grown fruit, whether the Apple or

the Pear, the Cherry or the Plum, because it contains its true lusciousness and flavour, developed by a distinctly suitable fruit-growing climate. The mealy productions of sunnier lands than ours have little of that delicious quality recognised in the Apple or other fruits grown in the British Isles. There are a few exceptions, and one is the famous Newtown Pippin, which refuses to bear abundantly in this climate.

Why are the British fruit growers to a large degree blind to their own interests in not facing this increasing foreign competition? We cannot answer a question that one would think in these days needless to ask. Probably it is due to a want of cultural details bearing directly upon the success of the tree, and when the variety is considered, its likes and dislikes, then it will yield an abundant return. Position, soil, stocks, pruning, and minor attributes to proper cultivation must be thought out, remembering that one variety will fail where another spells success, grown in the same climate and under the same conditions.

We hope that these notes will not be taken in an unkindly spirit; it is far from our wish to dictate to the fruit grower the methods he should pursue in raising the culture of fruit in this country to a higher level, but it has occurred to us that the following shortcomings are responsible for want of success. Exhibitions of fruit teach wholesome lessons. The annual display at the Crystal Palace under the auspices of the Royal Horticultural Society is witness to the great possibilities of fruit growing in this country. If the necessary £100 be not forthcoming to maintain this yearly display of fruit from various districts in the British Isles, then surely we must confess that failure is due to want of enterprise—a sorry confession in a commercial country. The beginner in fruit culture must not rely upon the exhibition for his selection of varieties. Many a noble fruit is seen there—a huge Peasgood's Nonsuch, maybe—that can never be accounted profitable. It is handsome and big, none too luscious, and there its value ends. More attention must be given to varieties capable of making a stir on the exhibition table, but richly prized, too, in the garden, or that appeal to those who require fruit of good quality.

An overwhelming abundance at one season signifies small returns, and the early autumn fruits quickly lose flavour and decay. The energies of the grower may well be directed to the winter supplies, and to achieve this desire varieties that naturally bear late ripening fruit

must be grown: not those that through elaborate storage preserve their freshness and colour until the spring. Their appearance is deceptive: the Apple painted with tenderest hue is a bag of mealy, unwholesome flesh.

Storage of late Apples is an essential detail in the routine of cultivation, but this is not a matter of great expense. A simple store is necessary—not an elaborate structure, which makes inroads in the bill of expenses at the outset of the business. We have a letter before us in which the writer, one of the most successful fruit growers of the day, says: "I have kept that good Apple, Cox's Orange Pippin, in excellent condition until the end of April in a cool dark store. The fruit was gathered late from dwarf standard trees." If such a sweetmeat as this luscious Pippin could be obtained at this season of the year in quantity, foreign importations would run little chance of acceptance at remunerative prices. Imported fruit is not cheap, but sold at almost prohibitive prices except to those indifferent as to household expenses.

We quoted prices paid for Wellington Apples, and, referring to the notes taken of the market recently, find that Northern Greening and French Crab are being sold at 5s. to 6s. a bushel.

Too many Apples is the universal complaint, and will be heard in the land until the grower undertakes to remove unprofitable varieties. If a tree fails to crop profitably after once obtaining a fair trial, remove it in the interests of the business.

The subjoined list has been prepared as a guide to the beginner and everybody who has failed to succeed. We hope our fruit-growing readers who have found the industry profitable, by cultivating varieties that fill the basket to overflowing, will give their valuable assistance in making the list absolutely reliable. Late Apples of good quality are desired, and to this section we look for useful additions.

This list is intended merely as the nucleus of a selection that few will cavil at. We leave to our readers the task of rectifying mistakes and admitting varieties of greater excellence than those at present recorded.

The fact cannot be disputed: fruit growing in England offers scope to young men with proper training and some capital to embark in the industry. A demand exists for good fruit, a food more wholesome and satisfying when gathered from trees in the counties of these isles. Apart from the question of varieties and culture, difficulties must be faced and overcome. A grower must have within reasonable distance a market or centre to dispose of his produce. Writing of fruit in general, dwellers in large towns know that of stone fruit—Plums, Damsons, and Cherries—there is never an over-supply. This may be remedied by creating greater facilities for disposing of the produce and preventing a glut at any one point. The supply of the west is of little value to the dweller in the north, as cost of carriage seriously lessens the profits.

The fruit-drying trade opens up another source of profit. This would prove a lucrative undertaking entered into with proper training and business acumen, and check the flow of foreign importations. We are writing now of fruit grown entirely in the open air, not under glass in any form. Produce developed under artificial conditions has its value, but the true hardy fruits must be regarded as belonging to the orchard and out-door garden.

FALSE IDEALS.

SCARCELY Mr. Leslie misapprehends the real question in writing as he does in THE GARDEN of February 21. One would think from the following passage that we had all been protesting against good lawns, comfortable seats, the pleasant and beautiful shade of the pergola, &c.:

Lawns are none the worse for being kept smooth and velvet, paths for being firm and free from weeds; strong, comfortable seats are not eyesores, fountains are at times desirable; a pergola shade of a well-designed summer-house for tea or shelter does not necessarily injure the general beauty. And in the same way a well-clipped hedge in its *right place* adds not only a comfortable feeling of home to the garden, but assists much in the general beauty as a foil.

But the question of hedges is outside of the central one altogether. Hedges are made for dividing lines, fences, backgrounds, &c. I like a Box hedge as well as anybody, but, unhappily, it will not grow well and rapidly with me, and do not object to a comfortable seat, and have even made pergolas people think pretty.

The question of clipping trees into false shapes is a wholly separate one, and to show the

evils of the practice let me give a few instances. Take the gardens in any district round London—Harrow or Colham, say; there we shall find that nine out of ten evergreens are clipped to get them into what the gardener calls "good shape," and we see the same thing done in our public gardens, as at Kew, and parks, as at the end of the Serpentine. If the man who wields the shears thinks that his aims at form are better than that which Nature gave to the Holly—well, we can only pray for his conversion! That is a real evil running through the whole gardening world, a false ideal in the simplest and purest sense. Can anybody find in the gardens in which this shearing is carried out a Holly as true and right in form as we may find in the first Surrey lane? The harm done by it it would be difficult to exaggerate, in concealing the true and varied forms of things even from the eyes of those who live most among them and sacrifice a good deal for their purchase and care. Mr. Leslie would, I am sure, be the first to see how much is lost, from an artistic point of view and from many others, by the wholesale destruction of the true forms of shrubs and trees and the creation of false and ugly shapes in them. He may be lucky in his own and neighbours' gardens, but those who take the trouble to see a great many gardens throughout the country will know how far this practice goes. Of course, once people get accustomed to false and ugly shapes in shrubs, they will gradually train themselves to put up with ugly shapes and patterns in gardens, even as regards the flowers and their disposition.

Now to come to the question of deliberate design. Take a few instances in which clipping into false and ugly forms is done. Some of our young landscape gardeners now fill their beds with forest evergreens. I do not like to name instances of private places, and the designer of some is a friend of mine. The beds that should be filled with flowers are filled with Yews, and the unfortunate gardener, after the first two or three years' growth, has to be continually clipping down these Yews into table-like shapes. This may be good landscape gardening, but no one, I think, will claim that it is good flower gardening. I think it is bad in both ways. The garden I mean is quite a recently made one. Let us go to an old one, at Northiam, in Sussex, which I saw last year, a very good and interesting old house and a very well-placed garden behind it well walled round. Against the wall on one side is an enormous line of clipped Beech trees, the roots taking up half the garden, and the rest of the garden is much occupied by clipped Yews, many of them large, absorbing all the nourishment of the ground.

I may be asked what I want. I should like to see the walls, which are very good walls, clad with Wistaria, climbing Roses, Clematis, and Jasmine—a real flower garden, in fact, as walls so often are, walls giving beautiful backgrounds—and I should certainly leave the forest Beech where it was "made" for the wood.

I need not take your readers to the mechanical instances of clipped gardens abroad, such as Versailles and Schonbrunn, hoping I have said enough to show that the evil of clipping in our gardens is quite a different one from that of hedges. But I should say that these may do very great harm if put down, as they often are, without thought of the gardener. In one of the places alluded to above the idea was to form a Rose garden, and the poor gardener had to put the Roses between close-set lines of Yew; and there he is still—between the devil and the deep sea.

W. R.

RIVIERA NOTES.

OF newer Tulips, *T. saxatilis* most certainly deserves the first place. It evidently enjoys warmth more than any other early Tulip, and its large Peach-blossom petals, with a yellow base, wide open in the sunshine, are most beautiful in this climate. It flowers quite three weeks before *T. Kaufmanniana*, and lasts fully a month in beauty in a season like the present. Altogether it is most desirable, and promises here to be free in growth.

T. Kaufmanniana, so far, is less satisfactory, and does not come up to its English reputation. It is stunted in growth, has none of the pretty red tinting outside seen in English gardens, and the lemon-white interior is uncertain in tone.

Tulipa Greigii also is stunted in growth this season, but when planted in a stiff and rather moist clay soil can be the most gorgeous of all Tulips either here or in England.

Curiously enough, *Iris reticulata* is far less charming in this climate than in England. Its deep blue-purple petals wither so quickly in the hot sun, that one day suffices to fade their beauty, and its sweet scent seems far less pronounced than in a colder climate. What delightful weeds the Starch or Grape Hyacinths are! Deep purple-blue, cobalt-blue, pale tender blue, and even pure white, they crop up on nearly every terrace, and will in due time be followed by the larger Feather Hyacinths, which latter especially are wild garden flowers, and do not show themselves to advantage in a trim border.

The special glory of this week is a *Magnolia Yulan*, with its grand, wide-open, Lily-like flowers, set off by the rich rose-red of a fine *Pyrus japonica*, one solid mass of flower, a sight for those fresh from the frost-bitten shores of the North Sea.

Daffodils are behaving very curiously this season. The heat and drought that continued till the end of the first week in December has evidently tried them severely, and the mid-season varieties were in flower before the earliest *Tendy* opened a bud. Thanks to the heavy rain and dull, chill days of January, the later varieties promise to be good, and *Anemone blanda* still carpets the ground under the shade of the trees on a northern slope.

Cinnia, Nica.

E. H. WOODALL.

NEW AND RARE PLANTS.**BRODIAEA (TRITELEIA)
SELLOWIANA.**

THIS is a new plant recently introduced from Monte Video, or the neighbourhood thereof. *Brodiaea (Triteleia) uniflora* is a well-known garden plant, hardy on dry soils, and makes a splendid edging to beds of such bulbs as Tulips. *B. Sellowiana* is more dwarf than *B. uniflora* both in foliage and flower-scape, and the flowers are very slightly smaller. But it has some advantages over the better-known species, as it is distinctly fragrant in a temperature of about 65°, its bright crocus-yellow colour being very telling.

I see no reason why it should not turn out to be hardy, as it comes from the same locality as *B. uniflora*. In a cool vinery it flowers with me in January and February, and is very floriferous.

Isleworth.

A. WORSLEY.

[An illustration of this plant appeared in our issue of March 3 (p. 162). If it proves as hardy as *Brodiaea (or Triteleia) uniflora*, it will be of much interest and value.]

LELIA ANCEPS HYBRIDS.

AS far as we know, there are only three garden raised hybrids produced from the influence of *Lelia*

anceps, and these have been derived from the dark section or typical forms. In addition to the garden raised hybrids, there are the supposed natural hybrids *Laelia Gouldiana* and *L. Finckeniana*, the latter undoubtedly owing its origin partly to one of the white forms. The natural hybrids were fully dealt with in the last volume of *THE GARDEN* (p. 479), so there is no need for further particulars here.

The first hybrid raised under artificial conditions from the influence of *L. anceps* as a parent was the bi-generic hybrid *Epi-Laelia Hardyana*, derived from the intercrossing of *Epidendrum ciliare* and *Laelia anceps*. It first flowered in Baron Nathaniel de Rothschild's garden at Vienna in 1891. On November 13, 1894, Messrs. F. Sander & Co., St. Albans, exhibited it and received an award of merit for a plant from the same parentage. The habit of growth resembles more nearly that of the *Epidendrum* parent, but most of the growths have two leaves. The scape shows the intermediate characteristics of the parent species. The flowers

raisers, Messrs. J. Veitch and Sons. It was derived by Mr. Seden from the intercrossing of *L. anceps* and *L. purpurata*. This is by far the finest hybrid of this section, and is certainly one of the most distinct and beautiful hybrids produced of late years. In the habit of growth the influence of the *L. anceps* parent is apparent. It is like a glorified form of that species. The long flower-scape also shows the influence of *L. anceps*. On its apex three flowers are produced, which more closely resemble those of *L. purpurata*, but the intermediate characteristics of the parents are plainly defined. The sepals are 3 inches long, rosy lilac, and the petals as long as the sepals, 2 inches broad, pointed as in the *anceps* parent, and also rich rosy lilac. The lip is upwards of an inch broad, the outer margin bright rose, the whole of the central area of the front lobe being bright crimson, veined with a darker shade of colour; the side lobes rosy lilac, shading to yellow towards the centre. At the base there is a suffusion of brownish purple and numerous longitudinal purple reticulated lines, as seen through the base of *L. anceps*. It received a first-class certificate from the Orchid committee of the Royal Horticultural Society on February 27 last. H. J. CHAPMAN.

LAELIA EDISSA (L. ANCEPS - L. PURPURATA).

(Shown by the raisers, Messrs. J. Veitch and Sons, at the Royal Horticultural Society's meeting, February 27 last, and given a first-class certificate.)

resemble those of *L. anceps* in shape and are in colour almost white, only the faintest trace of colour being observed except on the front lobe and tips of the side lobes of the lip, which are crimson-purple. It is a most interesting and desirable addition, and should prove a free-flowering and useful winter-flowering hybrid.

The second hybrid to appear from the influence of *Laelia anceps* as a parent was *L. amena* (*L. pumila*

L. anceps). This interesting little hybrid was raised in Mr. C. L. N. Ingram's garden near Godalming, and was exhibited by the raiser on October 9, 1894. The plant shown was very small, and resembled *L. pumila* to a remarkable degree both in the habit of growth and in the flowers. Though resembling the seed parent so closely, many characteristics indicate the influence of *L. anceps*.

The last of these hybrids (*Laelia Edissa*) to appear is represented in the accompanying illustration, reproduced from a photograph kindly sent by the

to Schwetzingen, near Heidelberg, to take charge of the splendid herbarium of *Gartendirector* Leyher. He remained here for two years; and then, in company with the famous Professor Spenner, undertook his first *Stadtausreise* to the Black Forest. On his return he was appointed to a responsible post, under Inspector Siming and Professors Nees and Eisenbeck, in the Botanic Garden at Poppelsdorf, near Bonn, and he resigned this position before he had held it a year in order to visit the Rhine and Switzerland. His next place of residence after Poppelsdorf was Munich, whence he made pilgrimages on botanical research intent to the Tyrol and Italy. After following his profession in Vienna for a while, he also visited Prague and Dresden. Then he made a brief stay in his native city, which was brought to an end by his acceptance of the office of head-gardener at the Agricultural College in Brunswick. He later acted in the same capacity for Baron von Carnap, but was obliged to leave that nobleman's service owing to

a lameness in one of his arms. Thereupon he returned to Berlin and founded the celebrated nursery, which some time ago he made over to his son Adolph. After the transference he retired to his extensive estate in Friedrichsfelde, but he did not finally settle down until he had gratified his wish to see Paris and Copenhagen and had revisited Italy. It is hardly necessary to add that Herr Demmler is a member of most of the leading German botanical and horticultural societies, and that the fact of his attaining the ninety-first anniversary of his birth in excellent health brought him hundreds of congratulatory letters and telegrams from all parts of the Fatherland.

W. D. CHILD.

Schönberg, Berlin, Germany.

CAMELLIA LADY AUDREY BULLER.

We much regret that in our last issue we should have let pass without notice, until the whole had gone to press, the incorrect form (Lady Buller) in which appeared the name of the wife of the heroic general whose guidance of the most arduous part of the South African campaign the whole country has been breathlessly watching. The name, which of course should have been Lady Audrey Buller, was taken down as it stood, and the error, unfortunately, escaped us till it was too late to correct the mistake. Eds.

PRESERVATION OF CHOICE APPLES.

AN interesting article on this subject appeared in the January number of the Belgian *Bulletin d'Arboriculture, de Floriculture et de Culture Potagère*. It describes the result of some experiments that had for their object the prolongation of the time during which Apples could be kept unshrivelled and in good condition. The operation consisted in the packing away of the Apples in cases filled up with dry sifted peaty powder. The greatest care was taken to ensure that only perfectly sound fruit, without bruise or other injury, should be submitted to the trial. The peat (peat-moss litter was found to answer well) was dried and beaten as small as possible and sifted. The Apples were each wrapped in thin newspaper or tissue paper, and packed round with peat powder. Care was taken that no two fruits should touch, but that each should be isolated by a sufficiency of the peat; the top layer was covered with a good thickness, and the case carefully closed. It is said to be important that the fruit, after gathering, should stand for a certain time in the fruit room till the usual sweating has taken place, whereby the excess of moisture is thrown off. It is then in the best possible state for packing.

It appears from the results of these experiments that, though the coarser kinds of soft Apples lose their flavour, the flavour, colour, and all attractive qualities are perfectly preserved in the case of the best dessert kinds. We are told that the fruits were packed in the beginning of November, but though it was not clearly stated when they were unpacked for testing their quality, we gather that it was certainly several weeks after their usual season of maturity, and that it was the opinion of those who conducted the experiment that it might be possible to preserve the Apples in this way until the beginning of the next season.

Pears were also tried, but with little success, as in the case of this fruit it was found impossible to retard the natural season of ripening; in their case the only advantage secured was that of avoiding shrivelling or accident.

It is well known that there is something about peat of a wholesome antiseptic nature; probably this beneficent quality, in conjunction with the keeping away of the drying influence of the air, has to do with the satisfactory preservation of the fruit.

The same journal, in its issue for February, accentuates the good opinion so generally expressed on the merits of the new perpetual-fruited Strawberries raised by the Abbé Thivolet. The second

of this series, St. Joseph, is becoming known in England, and we shall hope during the coming summer and autumn to hear of the result of its cultivation from gardeners in many different districts. Meanwhile, this has been followed by a still better and more continual bearing variety, named St. Antoine de Padoue, which was obtained by the crossing of St. Joseph with the Royal Sovereign. We may be assured of its merit when we learn that it was awarded a first prize by the Horticultural Society of France, but, meanwhile, we have to learn how it fares with us. For the opinion of good gardeners in this country we shall have yet to wait awhile, as it was only last autumn that it was put into commerce by Messrs. Vilmorin, of Paris.

SOME HARDY FLOWERS AT THE DRILL HALL.

At the Royal Horticultural Society's show in the Drill Hall on February 27 there was, notwithstanding the gloomy weather, a fairly representative exhibition of the hardy flowers of earliest spring. Messrs. Wallace showed the new Iris stenophylla, but the dim light of the room prevented a due appreciation of its pure colour, which is a clear blue, the widened ends of the falls being marked with a deep purple blotch. Its height is about 5 inches, and it was awarded a first-class certificate. Other Irises shown by the same firm were the dwarf yellow I. Danfordiae, I. histrioides, I. stylosa, I. reticulata major, and I. reticulata Krelagei. Other plants on the same stand were Anemone blanda in varied tints, Muscari praeox, and Galanthus Whittallii. Amongst Mr. T. S. Ware's exhibits were Saxifraga Bauseriana and S. apiculata, Adonis amurensis, a form of the winter Aconite (Eranthis cilicica), Hyacinthus azureus, Leucojum carpatium, which appeared identical with the spring Snowflake (L. vernum), Galanthus Elwesii giganteus, and two pans of Cyclamen Atkinsii album and C. A. purpureum. Species of Crocuses were well shown by Messrs. Barr and Sons, comprising Crocus reticulatus, C. Sieberii, C. cruseus, C. Olivierii, C. susianus, C. biflorus, C. chrysanthus albus, and C. c. fusco-tinctus. A good pan of Iris stylosa alba was also exhibited, as well as Cyclamen comm. roseum, C. ibericum rubrum, C. l. roseum, Galanthus Ikarie, C. Fosterii, G. Elwesii, G. robustus, Narcissus cyclamineus, N. minimus, N. Bulbocodium albus, and N. B. citrinus major, while numerous bunches of Lenten Roses were also staged. Of greenhouse plants, the invaluable Primula floribunda was represented in more than one collection, while amongst Messrs. W. Cutbush and Sons' exhibits were Primula denticulata alba, Daphne indica rubra, the sweetly-scented Boronia megastigma and Acacia Drummondii. A number of plants of Clematis indivisa lobata in full bloom were shown by Messrs. W. Paul and Son amongst a large collection of Camellias, while Messrs. Cammell were responsible for an array of well-grown Cyclamens. A fine group of the vivid orange Lachenalia Nelsonii was exhibited by Lord Suffield.

S. W. F.

NOTES OF THE WEEK.

A winter garden for Dundee.—The city of Dundee has decided to spend £5000 on a winter garden, while Edinburgh, which some years ago received a legacy to be spent on the erection of one, lags behind. It seems strange that the latter city, for so long a time famed for its nursery gardens, should be so backward in the cultivation of flowers in its parks, and also hesitate to avail itself of the benefits thrown in its way. R. P.

Acacias in California. Many of the leading sorts of Acacias are in full bloom now (January 20) and in great profusion. They are much healthier and more free from insect pests than ten years ago, and it begins to look as if Acacias would again be planted extensively, for the effect of large masses of the best sorts, on our hill-

sides is magnificent. I send a photograph of a group in the University grounds showing A. mollissima, a favourite Acacia here, growing against a mass of Pines on a gentle slope. They are about twenty years old and in excellent condition.—C. H. S., Berkeley, California, U.S.A.

Sugar Beet.—The Sugar Beet Committee of the Central Chamber of Agriculture have decided to make arrangements for a series of not less than twenty experiments in the growth of Sugar Beet in different parts of Great Britain and Ireland during the forthcoming season, each experimental plot to be at least one acre in extent. As, in certain cases, previous experiments have demonstrated the value of Sugar Beet for the feeding of stock, independently of the value of the root for the manufacture of sugar, this point will be specially kept in view in connection with the proposed experiments of the present year. *Nature*.

Zonal Pelargoniums for a long journey.—Pelargonium cuttings, if taken the right way, can easily be sent long journeys of three weeks or so. The great point is to choose ripe, hard wood and to pack perfectly dry, the only moisture being that contained in the cuttings themselves. It is best to cut extra long, for this reason: on arrival both bottom and top of the cutting are brown and decayed, but a cut of the knife to a new joint shows sound. An expert in tropical gardening from Port Royal Mountains, Jamaica (elevation 2000 feet), was in England not long ago and particularly wanted Pelargoniums of a certain kind from a friend. The cuttings were, however, cut as for home use, and they arrived a sodden mass of brown decay.

The National Dahlia Society will hold its annual exhibition at the Crystal Palace on Friday and Saturday, September 7 and 8. A committee meeting will be held at the Drill Hall, Westminster, S.W., September 25, for the purpose of awarding certificates to seedling Dahlias. The committee will meet at 12 o'clock. A few of the more important classes are for sixty Cactus varieties, not more than two of a sort, shown with their own foliage; twelve varieties, six blooms of each, to be arranged with any suitable foliage in vases, which will be provided by the society. The stems may be stiffened with wires, but no wire frames may be used. The Duchess of Sutherland (patroness) offers a special prize of £2 2s. for the best eighteen fancy Dahlias.

Vitality of Acacias in California.—Few plants introduced into California are as much at home as the Acacias, which readily reproduce themselves in most places. The capacity of the large feather-leaved kinds, such as A. decurrens, A. mollissima (which is often rated as a variety of decurrens), and A. dealbata, to grow when broken down has often proved surprising. I send a photograph showing the appearance (January 18, 1900) of a stump of A. mollissima growing on the grounds of the University of California, Berkeley. This tree was broken off in August or September, 1899, by a wind-storm. It grows on a hill-side in a cañon, and the shallow, rocky soil has not been cultivated for years, but a good many forest trees were set there about 1882 and have grown well. The young growth can be plainly seen near the top. Other buds are developing near the base and at various points around the trunk.—CHARLES H. SHINS, Berkeley, California.

Crocus Sieberii and C. Olivierii.—I had intended writing a note earlier than this about these pretty Crocuses. I am glad, therefore, to see the pleasant and appreciative notice by "F. N. A. G." in THE GARDEN of February 24. They are both a little later here than C. ancyroneus and form charming companions in clumps grown side by side. I once read a reference to C. Sieberii, which said it "is a hardy mountaineer, anticipating all others." This latter clause is not quite literally correct, as it is not the first of the Crocus species to flower. It is, however, such a dainty and hardy little flower that it ought to be grown by everyone who cares for our earliest blossoms, which peer through the snow in a season such as this has been. Your correspondent has, I think, solved the difficulty of describing its colour better than many in calling it of "a peculiar mauve shade," although

even this description is hardly so clear as one would wish. It is sometimes called blue, which it is not. In C. Olivierii, again, we have an orange-yellow of wonderful depth. It is a real orange, and yet wonderfully bright. Like C. Sieberii, the dwarfness of the plant is greatly in its favour when we consider the weather it has to contend against. One is hopeful that notes such as that of your correspondent will bring home to many readers how much they miss by not growing such flowers as these. Crocus Sieberii is, I believe, more variable in size.—S. ARNOTT, Carsbothon, by Dumfries, N.B.

Crocus Sieberii and C. Imperati.—I can endorse all that "F. N. A. G." (p. 149) says of Crocus Sieberii; it is most charming. C. Olivierii I do not know, but will look after it. I think he must live in a very cold region, for with me (near Dublin) C. Sieberii has been in bloom all January on a sunny bank quite unprotected and is still good, though we had some 14 of frost a fortnight ago. C. Imperati under like circumstances was in flower in December, and is now practically over, only the weakest bulbs being in flower. I think C. Imperati varies a good deal; at least, C. l. longifolia does. I got a few bulbs of the latter a year or two ago. Some have the feathering very pronounced and very dark, while others are almost—some entirely—destitute of it, being clear pale buff. The ordinary form, I believe, varies a good deal, too, but I cannot speak from experience, as my stock has all originated from six bulbs and is practically uniform.—G. P.

(Our correspondent "F. N. A. G." writes from Maidenhead.—Eds.)

Mutisia decurrens.—Although I do not happen to possess this pretty climber at present, I have had several opportunities of seeing it and learning something about its ways. I believe that the main difficulty lies in inducing it to take to the place in which it is planted. It is hardy with us in several parts of Scotland. I think the late Mr. Charles Jenner was one of the first to establish it near Edinburgh in his garden at Easter Duddingston Lodge. It did well with him in the open, and, so far as I can recollect, with the lower parts of the plant partially shaded by the other climbers in what the owner called his "climber garden." I find, however, that some have had a similar experience to myself in failing to establish it, even if the plants were strong ones and turned out of pots without disturbing the ball of earth. I lost a fine plant last year, but I am hopeful, from what I have seen of it, that I may yet be more fortunate. Perhaps "T. J. W." will also try again.—S. ARNOTT.

The twin-flowered Snowflake.—Few who know it will deny that the Spring Snowflake is among the most precious of our early flowers. Even those of us who have a deep admiration for the lovely Snowdrop cannot but admit that the Snowflake is in some respects its superior with its exquisite satiny white bells so beautifully tipped with green or yellow outside. The species or variety of Leucojum vernum to which I now refer is among the best of its forms. It is often grown as L. v. carpatium, and is distinguished from the common vernum by its earlier blooming, its taller growth, its larger flowers, its always producing two flowers on a stem when established, and by the deep green of the spot on the tips of the segments. It is a little unfortunate that there are two plants sold under the same name. The other has yellow spots, and generally produces one flower. It is also later in coming into bloom. If one could persuade nurserymen to follow Mr. J. G. Baker's nomenclature in his "Hand-book of the Amaryllidaceae" and call the tall robust form with green spots and twin flowers L. vernum var. Vagnerii, and the form with the yellow tips L. vernum var. carpatium, it would be a gain and save some confusion. I fear, however, it is too much to expect this. I think some readers may like to know that there are two Snowflakes sold under the same name. This year the variety Vagnerii is rather later than usual, but it has had fully open flowers here for more than a week before this (February 28). I always look forward to the coming of its fine flowers.—S. ARNOTT, Carsbothon, by Dumfries, N.B.

Narcissus cyclamineus from Cork.

I went out to see my Daffodil grounds this morning, and to my great delight found several sorts fully open, and in the grass garden got the enclosed in a sheltered spot from seeds merely dropped—not purposely planted; simply accident. W. BAYLOR HARPLAND, *Cork, February 22.*

Snowstorms. The chief damage done by the recent heavy snow has been to the large Rhododendrons. Several of mine have suffered severely, and it may interest you to see the enclosed section of one of the many branches which were broken off. The section measures just a foot in circumference, and was taken at 6 feet from the main stem. Fortunately, it is but seldom that one is able to burn logs of Rhododendrons. A. KINGSMILL, *Harbour Wood, Middlesex.*

[The section of wood sent must have come from a very large Rhododendron, for it measures 4 1/2 inches in its wider diameter. The wood is tough and whitish, and the medullary rings indicate an age of about twenty-six years. Eps.]

Fuchsia globosa outside at Hitchin.

I am much interested in the remarks about hardy Fuchsias in "Answers to Correspondents" of THE GARDEN, February 24. I have here a large plant of hardy Fuchsia which I believe to be *globosa*. It has stood out for twenty years, and has never been cut down and protected at the root in the ordinary way; indeed, the knife is only used on it to remove wood that has died naturally. The last six winters have left it practically untouched, and it is now a large shrub over 7 feet in height and solid in growth. It flowers most freely. This garden is on a chalk hill 300 feet above sea level in the extreme north of Hertfordshire, with a slope to the west. The Fuchsia stands in a border facing due west, with a good wall at the back. F. A. TINDALL LUCAS.

Asparagus tenuissimus.

We have now several forms of the delicate *Asparagus plumosus* in cultivation, all of which have attained a considerable amount of popularity within recent years. The most generally grown is *A. plumosus nanus*, a charming plant in every way. It can, however, only be increased by means of seeds, whereas the pretty *tenuissimus* may be readily struck from cuttings. In this variety the branches are not arranged in a flattened frond-like manner as in *nanus*, but more in the way of *A. plumosus* itself. The variety *tenuissimus* is, however, far more slender in all its parts than the typical *plumosus*; indeed, so exceedingly light in texture is it, that when studded with moisture it appears little more than a cloud of mist. It is of a climbing habit, and is a delightful rafter plant for a small structure. Owing to its being easily struck from cuttings, neat little plants that are extremely useful for many decorative purposes may be formed by putting from four to six cuttings around the edge of a 3-inch pot, and placing them in a close propagating case in the stove. There they root quickly, and after being hardened off may be shifted into larger pots, where they will form globular masses of delicate bright green foliage. Plants obtained in this way retain the dwarf bushy habit for some time, but as soon as they develop strong shoots from the base they mount upward quickly. H. P.

Cytisus filipes.

It would be difficult to find a more graceful subject among the innumerable occupants of the greenhouse than a well-grown specimen of the Tenerife Broom (*Cytisus filipes*), which, though an old plant and, generally speaking, well known, is very rarely met with. It is of free growth, with long slender semi-pendulous branches, which are for the greater part devoid of leaves, their place being taken by bright green shoots. The flowers are white, and borne as a rule in February and March, a succession being kept up for some time. It is not at all exacting in its cultural requirements, needing little more than to be kept free from frost. This Broom is seen to particular advantage when grown as a standard, as the long cord-like shoots have then ample space for their development, and a few good specimens are very serviceable for grouping purposes. To obtain standards it is often grafted on to vigorous seedling stems of its near ally, *Cytisus racemosus*, or sometimes on to the *Laburnum*, but the first named

makes the best stock. Grafting is, however, not absolutely necessary, for seeds are sometimes produced, and when this happens they germinate readily if sown in the greenhouse, and the young plants may then be tied to a stick and limited to one shoot till the required height is reached. Pretty plants, too, may be produced by securing the leading shoot to a stick and allowing the side branches to grow at will, the result being a kind of loose pyramid. H. P.

HOW FLOWERS ORIGINATED IN NATURE.

It is now a fact familiar to all that the parts of flowers are really identical in their nature with leaves and are interchangeable with them. Thus the green Rose illustrates this by having its carpels, stamens, and petals in a foliaceous condition; so that if we wish to speculate when flowers first came into existence we must look

A CORNER OF THE GARDEN AT HOLME LACY.

IN THE GARDEN AT HOLME LACY.

The accompanying illustration shows a view in the beautiful garden at Holme Lacy, Herefordshire, the residence of Mr. Pilkington. The garden is one of the most interesting in the county, and is rich in striking pictures produced by contrast of flowers with the sombre green of well-kept Yew hedges.

back to the first change discoverable from leaves or leaf-scales, which are rudimentary leaves, to floral organs.

The geological history of plants is, however, so imperfect, that nothing has been discovered to throw light upon the origin of flowers. Many reasons exist, however, for believing that the conifers have descended from the higher cryptogams, such as Ferns, plants like *Welwitschia*

and Cycads, but at present we can only speculate. The conifers probably gave rise to ordinary dicotyledons, but the links are wanting. When we examine the male inflorescence of the Cypress and Fir, we find evidence of stamens being constructed out of scales, which remain green in the former, with four yellow anther cells at their base, but in the latter the whole scale is yellow.

Now whence came petals? Here we are on safe ground, for the Water Lilies illustrate the process: as well, indeed, does the ordinary procedure in the production of double flowers, for we find the filaments widening and the anthers disappearing by degrees till a stamen is represented by a petal. What induces the change to arise? That the alteration is the result of a response to some external influence seems obvious, but how Nature does it, is a question we cannot answer.

There are two kinds of stimuli. One follows on the visits of insects mechanically probing and irritating the flower in search of honey or pollen as food. The other consists of the external physical conditions of water, soil, and climate generally. If it be asked what flowers are the most primitive in type (apart from conifers), one would say such as the *Ranunculus* family, because the stamens and carpels are numerous and spirally arranged like leaves on a shoot, while entire freedom prevails throughout the flower. Cohesion, *i.e.*, union between the parts of the whorls, and adhesion, *i.e.*, union of different whorls, are entirely wanting. Both kinds of union are regarded as of a later or more advanced condition in flowers. Hence the usual order adopted in the classification of plants according to the natural system corresponds to a considerable extent with the supposed order of their evolutionary history. Thus dicotyledons have four great groups of orders. The first has all the petals free; the next has the petals adherent to a honey-secreting disc, called the receptacular tube; the third always has the petals coherent into a tube; while the fourth, called "incomplete," contains plants which are probably in all cases degradations from some members of the preceding groups. They have no corolla at all.

The next point to observe is that when petals were first made they were all alike in the same flower. The corolla is then called "regular," as of a Buttercup. Subsequently some became irregular, as Larkspur and Aconite, *Salvia* and Dead Nettle, Snapdragon and Foxglove. The question arises, How did their changes come about, for all irregular flowers have undoubtedly descended from regular ones; to which, indeed, they frequently revert, as in the terminal blossom of a spike of Larkspur, Foxglove, Horse Chestnut, Pelargonium, &c.? The probability is that the irregularities of all sorts are due to the irritations set up in the flowers by the insects themselves.

The first point to note is that irregular flowers are arranged up a stem so close to it that insects can only visit them from the front, but regular flowers, being terminal, can be approached from all points of the compass. Special adaptations are then correlated with their positions, such as the frontal lip, which acts as a landing place, as in Labiates and Orchids. It may be observed that in some of the latter (Orchids) the inferior ovary having no central axis, so to say, gave way under the weight of the insect and became twisted, thus acquiring strength, but the consequence was that the posterior petal now fell in front, the result being that this petal, and not the anterior one, enlarged and became the landing-place. If there be no exactly anterior petal in front, then the stamens undertake to carry the insect.

This they do by becoming declinate—that is, by inclining downwards and then turning upwards again. They then become strong, elastic springs, as in *Rhododendron*. The honey-glands will be found to be always localised in irregular flowers at the base of the flower, just where the proboscis of an insect will find it, whereas in regular flowers the glands occur all round, as in *Geranium*, or from a circular trough, &c., as in the Raspberry. "Guides" consist of extra streaks and spots of colour on the petal exactly over the position of the honey-gland, and are due to local irritations with special increase of colouring matter. These are the more obvious correlations between the structures of the flowers and the insect-visitors.

The actual minutest structure of the sepals and petals often shows a further response to the mechanical forces exercised by the insect. Thus, in the Labiates the tubular calyx, which is composed of five coherent sepals, ought to have only five ribs, *i.e.*, one dorsal or midrib to each. To strengthen it, however, as a support

flower rather than to the stigma of the same flower. That plants respond readily to mechanical strains by altering their internal anatomical structure is well known. Thus, if a weight be attached to a small growing stem just sufficient not to break it, in a few days it will have added supportive tissues to meet the strain; indeed, more than sufficient to bear a much greater weight than it could have done if left alone.

It is by the accumulation of facts such as the above, as well as others, that the belief that the irregular flowers have been derived from regular ones is confirmed, and that it has been brought about by the actual insect-visits.

Next, as to colours. As Pine trees have yellow anthers, it would be reasonable to infer that yellow is the first result of a change from green chlorophyll. Red follows yellow, and is probably a result of insect stimulus, as also, as stated, are the extra guides on the petals. After red comes purple, and then, finally, blue. White may occur anywhere in the series as

ANEMONES AT HOME IN SOUTHERN ITALY.

for the corolla tube, five more are usually added up the coherent margins. But in such a flower as the *Salvia*, which has to support a heavy insect on its enlarged lip, additional cords or ribs are added just where the strains are greatest. The calyx is almost bi-lobed, as if stretched with a tendency to tear, while the distribution of the cords will be understood as follows: *D*, being original dorsal or midribs; *M*, marginal cords; and *S*, a supernumerary one in front, where the strain is greatest of all. As the joint result of the alteration in the corolla and positions of the stamens, the anthers become situated so as to dust the insect in such a spot where the stigma may strike it when entering another flower. Hence, all irregular flowers, and, indeed, all regular ones when conspicuous, are thus capable of having their pollen transferred to another

being the arrest of all colour, as in the Water *Ranunculus*, which retains the yellow at the base of the petals only. Brightly coloured flowers often revert to yellow, as the var. *citrina* of the crimson *Adonis*. Various *Chrysanthemums* sport, *i.e.*, revert to yellow, that being the colour of the original species, *C. indicum*. As an example of red advancing to blue there is *Anagallis arvensis* var. *caerulea*, the corolla of which retains the red in the tube. Lastly, some flowers have become degraded in consequence of the absence of the insect to stimulate and keep up their conspicuous features. The size is then dwarfed; the petals nearly or quite disappear; the stamens are often reduced in number. No honey-glands remain, and the flowers fertilise themselves, sometimes never expanding at all. The reader is probably familiar with such common weeds as Groundsel, Shepherd's Purse, Chickweed, Knot-grass, cleistogamous Violets, &c.

GEORGE HENSLAW.

OUR GARDEN PLANTS AT HOME.

ACANTHUS MOLLIS LATIFOLIUS.

This plant of noble foliage is of frequent occurrence through Middle and Southern Italy, Northern Africa, and other regions adjoining the Mediterranean. In hollow, half-shady places, in the cool bottoms of rocky valleys, at the foot of mountain masses, may be found the great sheets of its magnificent foliage. The leaves are broadly displayed to view by the arching of the midrib, which also so disposes them that the blue of the sky is reflected on much of the polished surface, while the remaining portions show their local colour of full rich green. The great leaves all come direct from the root, and from among them the flower-stems shoot up straight and tall, their upright carriage in striking contrast to the arched bearing of the foliage. The hooded flowers are of a tender white with a purplish tinge, which is repeated in the protecting hood. They spring rather thickly from bracts armed with spines so stiff and sharp, that the flower-spike is bad to handle. As the blooms give place to the rounded fruit the size of a plump acorn, the stiff, protecting hood remains and shelters it from the autumn rains.

Like other plants that are natives of Southern Europe and yet are hardy in England, though at home they like a shady place and the cooling nearness of great rocky masses or the mouth of a cave, as in our illustration, with us they must have all the warmth and sunlight we can give them. A bank of deep light soil, where their long, thick, thong-like roots can go down a couple of feet, seems to suit them best. They are noble plants anywhere, but perhaps look finest at the base of a bold rocky bank. They also associate happily with stone seats or any wrought stonework: indeed, the leaves of this noble plant have a long and honourable association with sculpture such as no other growing green thing can boast. For the beauty and graceful dignity of its form was quickly appreciated by the ancient workers in marble, and when the earlier orders of architecture had progressed from the rude and massive Doric to the stately Ionic, and when this had led to the more graceful and highly ornate Corinthian

and the still later Composite, in the two latter orders it was the Acanthus foliage that gave its form to the richly chiselled ornament of the capitals and to the enrichment of the sculptured ornament of frieze and architrave and much else of ornamental detail on many a building or other object of public dignity or domestic utility. And, again, in the Middle Ages, when the fine arts arose again upon the basis of the teaching of the great artists of ancient Greece, and those churches and palaces and gardens were built and made, and those pictures were painted that are still among the greatest of art treasures, again the beauty of the Acanthus is recognised, and its ever-recurring form runs through all the best of the ornament of the Italian Renaissance. In marble, in bronze and iron, in delicate working of silver and gold, in cunningly carved wood-woodwork of throne, choir-stall, and canopy, and in every detail of the interior of palatial dwelling, of municipal building or of vast cathedral; wherever ornament rightly applied grew out of structure—not only in marble, wood and metal, but in painting and pottery and in woven fabric—the noble lines and forms derived from the Acanthus grew and thrived, conceived in adaptation of suitable use by the brain of the artist, and wrought in the same spirit by the sympathetic hand of the craftsman.

ACANTHUS IN MARBLE CAPITAL OF AN ANCIENT COLUMN.

TREES AND SHRUBS.

CATALPAS.

THIS genus of large deciduous trees is represented in both the eastern and western hemispheres and contains about a dozen species. Only five of these are at present in cultivation in Britain or are known to be hardy, two being natives of North America and three of China. The Catalpas are some of the most striking and beautiful of all hardy trees both in regard to foliage and to flower. The leaves are large and bold in outline, and the flowers borne in large terminal panicles towards the end of summer. Catalpas love a rich soil and abundant moisture. They are particularly well adapted for planting on the margins of ponds and water-courses. All the species have this peculiarity: they never form a terminal winter bud. In consequence of this, every shoot branches at its apex into two or three every spring, with the result that the trees naturally acquire a broad, spreading habit. This is especially apparent in the case of isolated trees growing on lawns—a position, it may be mentioned, in which Catalpas are seen to exceptional advantage.

In the forests of North America, where they are drawn up by other trees, the Catalpas occasionally attain to heights of 50 feet to 100 feet. In gardens it may sometimes be advisable to help them to reach a moderate height by keeping them to a single lead when young. All the species can be increased by cuttings of the roots or of the fairly-matured leafy growths.

The wood of the American Catalpas, although comparatively soft, is valued in the United States because of its quality of resisting decay when in contact with soil or water.

C. BIGNONIODES (SYN., *C. SYRINGEFOLIA*),
INDIAN BEAN.

Having been introduced from North America in 1726—more than a century in advance of any

other—this species is by far the commonest and best known of the Catalpas in Britain. It does not often attain a stature of more than 30 feet, although in its native woods it is met with twice as high. The broadly ovate leaves are in healthy trees of mature age about 6 inches long and 4 inches to 5 inches wide. The flower-panicles are erect, branching and pyramidal, frequently 1 foot in diameter at the base. The flower is 1½ inches across, with a broad, bell-shaped base, the reflexed limb being elaborately frilled. The colour is a creamy white, blotched with yellow and spotted with purple in the throat. The thin kidney-bean-like fruits are 9 inches to 12 inches long, but in most parts of the country are only produced after exceptionally sunny seasons like that of 1899. It flowers in July and August. This tree occurs in the South United States, and was figured by Mark Catesby in his "Natural History of Carolina" as long ago as 1731.

The following varieties are in cultivation: *Aurea*, with rich yellow foliage; *nana*, a remarkable low shrub, 2 feet to 3 feet high, which never flowers, and must therefore be regarded as a curiosity merely; *purpurea*, with purple-tinged leaves and shoots.

C. BUNGEI.

Whether the true *Catalpa Bungei* is in cultivation at the present time is very doubtful. Professor Sargent during a recent visit to Kew expressed the opinion that it was not, either here or in the United States. Certainly the plants supplied by some nurserymen under this name have nothing at all to do with it, being, as a rule, the dwarf variety (*nana*) of *C. bignonioides* that has already been alluded to. Even plants raised from seeds imported from China have proved to be *C. Kämpferii*. In any case, the true *C. Bungei* has not yet flowered in Britain. It is a tree 30 feet high, with the leaves either entire or lobed, as in *C. Kämpferii*, but of more triangular outline and with a longer, more acuminate apex. They are 4 inches to 8 inches long and about three-fourths as wide. The flowers are white, spotted with purple, they as well as the panicles being larger than in *Kämpfer's* *Catalpa*. It is a native of Northern China.

C. CORDFOLIA (SYN., *C. SPECIOSA*), WESTERN
CATALPA.

Whilst this species is nearly allied to *C. bignonioides*, it differs from it in geographical distribution and in the characters of leaf and flower. The leaves are ovate, but drawn out into a longer, more tapering point than in *C. bignonioides*. The panicles are larger: the individual flowers are also larger (2 inches or more across), but not so numerous. The corolla is white, with yellow blotches on the

ACANTHUS IN IRON TORCH-BRACKET, 16TH CENTURY

throat, but the purple spots are not so abundant. It flowers about a fortnight in advance of *C. bignonioides*.

This is probably the finest species of Catalpa, but is not yet well known in Britain. In the United States it is often 50 feet high, and in exceptional cases over 100 feet. It inhabits a more western region than *C. bignonioides*, and is found in the States of Kentucky, Louisiana, Tennessee, Missouri, Texas, &c. Professor Sargent, in his "Silva of North America," records a remarkable instance showing the power of the wood of this Catalpa to withstand decay when submerged in water. In 1811, owing to an earthquake, a large area of land in Missouri on which this tree and others were growing became submerged. All the vegetation was destroyed, but in 1878—or 67 years after—the trunks of the Catalpas were found to be still sound, whereas the other trees that had been contemporary with them had long since decayed and vanished.

Owing to its having been for a long time confounded with *C. bignonioides*, this species was probably introduced unknowingly, and it may exist in some gardens under the other name. It is said to be somewhat the hardier of the two.

C. FARGESII.

This is a new Chinese species introduced to France by Mons. Maurice de Vilmorin, and sent by him to Kew in 1899, where it is now growing. It will probably be a few years before it flowers, and nothing can as yet be said as to its value, except that in the size of its leaves it is fully as striking as any of the older species.

C. HYBRIDA (C. CORDIFOLIA × C. KEMPFERII).

It is now about twenty-four years since this hybrid Catalpa was raised by Mr. John C. Teas in Indiana, U.S.A. It has hitherto been generally known as Teas' Hybrid. In the United States it appears likely to prove the finest of all the Catalpas, exceeding even *C. cordifolia* in the vigour of its growth and the size of its panicles. Four hundred flowers have been borne on a single panicle; they are of the usual white, with yellow and purple markings on the throat. Generally the plant is intermediate between the two species that share its parentage.

C. KEMPFERII.

Whilst this species named in honour of Engelbert Kempfer, who visited Japan in the seventeenth century bears a strong resemblance to the American *C. bignonioides*, it is neither so fine nor so ornamental a tree. It has naturally the same rounded habit, but is never so large. The leaves differ in frequently being more or less lobed. The flowers are about 1 inch across, with reddish brown and purple markings. Kempfer noted this tree in Japan, and until a recent date it was regarded as indigenous to that country. Recent travellers have, however, concluded it to be (like many other popular trees in Japan) of Chinese origin solely. It is frequent in the grounds surrounding Buddhist temples in Japan. Introduced to Europe by Siebold in 1819.

Arboretum, Kew

W. J. BEAN.

THE ROSE GARDEN.

ROSA RUGOSA AND ITS BEST VARIETIES.

THE original species of this valuable tribe of hardy Roses, according to Thunberg, is a native of Japan, although Lawrence mentions it under the name of *R. ferax*, as indigenous to the Caucasus and having been introduced from thence in 1796. To show the wide distribution of this tribe, not long ago a variety of the species was found growing on the Rocky Mountains of America, and is now known as *America*, having been sent to this country by the Harvard University. It is a very large open flower, crimson-lake in colour. The whole tribe are deserving of a more extended popularity than they have hitherto commanded.

When we consider that they will endure with impunity 40° or more of frost, that the collection now consists of kinds bearing flowers almost as large as Hybrid Perpetuals, it seems inexplicable there is not a larger demand for them. It is true the type *Rosa rugosa* and *R. rugosa alba* are being extensively planted in game preserves, and it is found that pheasants and partridges are very partial to the seeds and pulp which these Roses so freely produce enclosed in their handsome fruit. Plants of the white and rosy-erimson coloured variety may be quickly raised from seed sown as soon as ripe. A nice sheltered, well-drained bed of loamy soil in which some sand has been freely incorporated would be all that is required. Sow in very shallow drills, keep the beds clear of weeds, and above all protect them from birds and mice. Perhaps two-thirds of the seedlings will be of the rosy-erimson variety even if the seed be sowed from *R. rugosa alba*; but should the latter form be most desired, plants may be propagated quickly by budding, or, better still, from layers put down in July. These *rugosa* Roses are conformable to a variety of uses, but perhaps the best manner they can be employed in is as hedge plants. Instead of planting so much Privet, one would beautify the garden or park far more delightfully with *rugosa* Roses than with that malodorous shrub. Certainly these Roses are not evergreen, but their foliage is so attractive during summer and autumn, the bold green leathery leaves being unmarked by insect or blight, that the planter obtains ample recompense.

There are numerous floral gems that require a sheltering hedge to screen them from cutting winds. What more suitable subjects are available than these *rugosa* Roses? They are the most accommodating of shrubs, flowering as freely if pruned hard as they will if left unpruned. I have seen the type forming a hedge fully 8 feet in height, and a perfect picture when adorned with its numerous and showy fruits, which, by the way, make a good conserve. As a background to the herbaceous border, the orange-scarlet of the fruit would give a tone of colour very acceptable in the autumn months when so much yellow abounds in the extensive *Helianthus* family. When planted as hedges, great watchfulness is necessary to see that the plants produce some new wood each year, otherwise the bottom part of the hedge will be devoid of foliage. A shrub loses a good deal of its attractiveness when it becomes bare of foliage and branches towards the base. If a tall wall-like hedge is desired, a double row of bushes could be planted, which would enable the planter to prune the front row rather severely, and thus hide the want of foliage of the back row, or the second row might consist of the lovely single rather dwarf growing *Rose Andersonii*, whose glowing fruit in autumn would harmonise so well with its more vigorous companion.

Perhaps some day our great railway companies will awaken to the fact that it is possible to beautify the banks abutting the iron roads which they control with cheap flowering shrubs, and one of the many lovely subjects for the purpose would be *R. rugosa*. For open spaces, recreation grounds, and such like places our corporate bodies would find in these Roses a shrub well suited to plant therein

in conjunction with Lilacs, Weigelas, Ribes, Spiræas, &c. As standards the double forms are a grand success on account of their great hardiness and ability to resist violent gales. One kind, *Blanc double de Courbet*, deserves special mention: it is the purest snow-white flower possible to find among hardy shrubs. This would certainly be the variety above all others that I should recommend if asked to name the best *rugosa* Rose. Picture a great spreading head of grey, half-pendulous growths covered with thick, leathery, rich myrtle-green bunches of exquisite semi-double white flowers, and one can obtain some idea of the beauties of this Rose, but no verbal description can do justice to the wonderful formation of the pretty elongated buds which only need a little longer stem to make them commercially valuable to the florist. This variety is deserving of a conspicuous position on the lawn. Give it a good start by trenching the ground and affording some good lasting fertiliser, and it will be an object of beauty for many years. One cannot expect fine showy flowers and fruit if the plants are neglected. New wood must be encouraged by cutting away old branches now and then before the plants start into growth, and in fact similar cultivation should be afforded as is given to what many consider superior Roses. A pretty cone-like mass of *Blanc double de Courbet* or *Mme. G. Brant* could be produced by planting a standard in the centre of a bed and about three bushes around it. The standard if possible should be double budded, with a space of 15 inches between each bud. An alternate plan would be to plant out a strong bush and when established layer three or four branches round, the layers, of course, remaining undisturbed. When necessary, a centre stake could be afforded to the older bush, so that in time a splendid pyramid of snow-white blossom would be the result. I am not sure that I care for the majority of double forms of *Rosa rugosa* which seem to be the aim of our hybridisers. That the flowers are more lasting cannot be denied, but we are in danger of losing one of the greatest charms this tribe has hitherto possessed, and that is their gorgeous fruit, and, moreover, there are double Roses galore in the Hybrid Perpetual and other groups. The only reasonable excuse for producing these double kinds is that we are providing the dwellers in the vicinity of smoky districts with a class of Rose which, by reason of its leathery foliage, smoke does not seem to harm, and its extraordinary hardiness may in some degree replace the Hybrid Perpetuals, many of which are not perfectly hardy.

I have nothing but praise for *Blanc double de Courbet*, but then it has its pure colour, fragrance, expanded shape, and thick petals to recommend it, and it is also a grand autumnal blooming variety. The double *rugosa* blossom rather earlier than the Hybrid Perpetuals. Last June the fine hedge of Mrs. Anthony Waterer at the back of the Rose dell in Kew Gardens was covered with a perfect mass of its rich crimson blossom simultaneously with many of the best single Roses, such as *Rosa lutea*, *Carmine Pillar*, *macrantha*, *hispida*, &c.

If *rugosa* Roses would thrive well upon railway embankments, obviously they would do so by the margin of lakes, or upon the small islands formed in the centre of ornamental pieces of water; they would if upon their own roots hold their own in the wild garden, and would certainly grow under trees as well as the Scotch Roses if care were taken when planting that their roots were provided with a good depth of soil, and not placed too close to any strong-rooting tree. Until recent years *rugosa* Roses consisted mainly of dull, cloudy, magenta-coloured varieties, excepting the whites. There is said to be more than one form of the original type, but I have never met with it. The profusion of yellow stamens in the single species is not the least of its many attractions; admirers of this group would warmly welcome a single form of *rugosa* with flowers as brilliant as *Bardou Job* or *Gloire des Rosomanes*.

Atropurpurea has the appearance of being a move in this direction. A good yellow would also be much appreciated. I think with patience this might be evolved by cross-fertilising *R. rugosa alba* with *R. hispida* or *R. lutea*. There is in the

Hardy outdoor flowers at Christchurch. The following plants are now in full bloom in the Riverslea Nursery, Christchurch: *Cyclamen coum*, *Iris Krelagei*, *L. hystrioides*, and a batch of seedling *L. reticulata*, amongst which are some very fine flowers; *Rhododendron praecox*, *Leucopium verum*, *L. x. carpatium*, and a very early form of *Sedum sibiricum*, which has been in bloom for the last three or four weeks; *Helicorus colebiens*, *magnificus* and other varieties. H. M.

Kew collection a beautiful rich crimson single kind with a white centre, received from the Arnold Arboretum. The vagaries of hybridised Roses are very remarkable: a similar cross to the above produced the double form Mrs. A. Waterer. I also saw at Kew an exquisite hybrid between *R. rugosa* and *R. macrantha* which had lovely clear pink single flowers and all the peculiarities in growth of *R. rugosa*.

Another interesting hybrid from the Arnold Arboretum was one which resulted from a cross between *R. Wichuriana* and *R. rugosa*. It possessed the procumbent habit of the former and gave one the impression of being a creeping variety of a Penzance Briar. The colour was a soft rose, foliage leathery but glaucous, and wood very spiny. I thought it one of the loveliest single Roses in the gardens at the time of my visit. *R. rugosa calocarpa* has never in my opinion deserved the high encomiums of the raiser when it was introduced. Perhaps in a drier atmosphere its fruits are more brilliant, certainly they are very abundant, but no larger, if so large as the hedge Briar, and they damp off so quickly in the autumn that a spray of fruit is invariably marred thereby. One of the finest kinds to grow, were fruit the sole consideration, is *Souvenir de Christopher Cochet*, but its flowers are very dull in colour. *Delicata* has been much admired; it is a very continuous flowering single variety of a most beautiful delicate soft rose colour. Among the oldest of the semi-double and double kinds *Mme. Georges Bruant* is a very worthy variety; although it does not produce seed-pods, its long Niphetos-like bud has accorded it a high position among garden Roses, and it should be extensively planted for its buds alone. It is a splendidly vigorous grower, equally adapted as a standard, pillar or bush. *Mme. Georges Bruant* was raised from a cross between *R. rugosa* and the Tea Rose *Sombreuil*, and was twelve years ago thought to be the commencement of a new race, but few have followed in its train.

Belle Poitevine is a very free-flowering variety, in fact almost always in flower. Its sweet, double, rose-coloured blossoms are much brighter than the usual run of this colour among Roses. The three following take their names from Hungarian mountains. They are really most interesting hybrids at present little known in England. *Hargita* has charming rich pink semi-double flowers not unlike a deep coloured *Blairii* No. 2, and the wood resembles in its prickles and ruby colour that of the old Rose named. *Tamogled* is very double; the buds are large and of a bright pink colour. *Jelina* is showy, having large double reddish-carmine flowers and magnificent foliage. *Thusaella* has splendid deep petals in colour not unlike the buff-pink *Bombon Queen*. These last four Roses are reputedly derived from crosses between *R. rugosa* or *rugosa alba* on the one side and yellow Tea Roses on the other. *Schneelicht* is an extra vigorous-growing kind with large snow-white flowers and very thorny wood. *Consul F. Meyer* promises to become one of the most valuable of double *rugosas*. It has buds resembling *La France*, and the large flowers when fully developed have a likeness to *Baroness Rothschild*. A reference was made to this Rose in "Notes from a Swiss Nursery," which appeared in *THE GARDEN* of October 7 last.

Fimbriata is one of those choice novelties found in nearly every tribe. Its pretty flowers, though small, are charmingly fimbriated like a *Primula* and are white in colour, shaded with the palest blush-rose. It bears distinct traces of its parentage, having resulted from a cross between *Rosa rugosa* and the Hybrid *Noisette Mme. Alfred Carrière*, the wood resembling in a great measure that of the latter. It is not at all showy on the plant, but must be cut and arranged to obtain the effect of its rare beauty.

Mme. Charles Worth, although the last to name, is certainly not the least. As a decorative shrub it is grand, yielding as it does large bunches of semi-double rosy-carmine flowers which are, moreover, very sweet. Its foliage is also most attractive.

PHILOMEL.

DAFFODILS UNDER GLASS.

SHAKESPEARE evidently had the kindly and patriotic trait which makes us attribute to all our English springs the graces which in stricter truth belong to only some of them.

"When Daffodils begin to peer . . . why then . . . the sweet o' the year" is too often deferred *sine die*. February can be a most exquisite month: a month of broad, soft airs which make us inland think of the sea; a month of reddening twigs and yellowing catkins, of cooing ringdoves and shoots up-breaking through the moist soil. But there has been little such amenity in the turn of the present year, at all events here in the uplands of North-west Hampshire. Even indoors the cool reflected light from the white expanse without gives to the rooms an uncomfortable and disproportionate look of too much ceiling. Outside there has supervened an ebb and flow of chilly rain and snow, slush and frozen slush ever since the deceitful gold of those indomitable December Aconites inveigled us into the spring mood. A full month ago the Daffodils were pushing into sight with sturdy leaf wedges and here and there a green bud. But to-day in the third week of February not even the spears of *Iris reticulata* or the long-necked

upon a time a neighbour's head gardener, an excellent man, though of the ancient grape, melon, and cucumber order, came to see my Daffodils. After making the round of all my seedling beds and dwelling observantly on my *chets-d'œuvre*, he took his leave in these words: "Well, all I can say, sir, is this: some of these flowers of yours deserve a pot; they are well worth a pot, sir." This eulogy was scarcely appreciated at the moment, but I understand now how encouraging it should have been. The old man had the eye of a life's experience—he has long ago passed away, I hope to the *Paradisus* of worthy gardeners—and knew the marks of a good flower from one important point of view. He meant that these Daffodils had been educated in size, symmetry, and colour to the rank of a florist's flower, a flower deserving of a little portable garden of its own, in which to be handled and fondled and turned about and set on a shelf for admiration or comparison with its rivals. Let no one scorn the notion as cramped and petty. The broader vision of profuse colour and form in our gardens resolves itself largely in its "ultimate analysis," into spike and cluster and solitary bloom which are our heritage from the restricted plodding of the florist proper.

A SEEDLING BETWEEN THE WHITE HOOP PETTICOAT AND NARCISSUS TRIANDRUS GROWN IN A POT

buds of *Crocus Imperati* can top the thick coverlet of snow.

In such a season, when the skies have chalked up "No thoroughfare" everywhere on path and border, the most uncompromising outdoor gardener may gladly betake himself to a refuge and a foretaste of spring in his greenhouse. No one can out-believe me in the creed that the hardy plant, at large in free air, is lord and master of all. Nevertheless, my five or six score pots of Daffodils are yearly a delight in the inclement days of February and March, and serve to add some three weeks to the reign of my favourite flower. And there is here the least possible artificiality: indeed, the film of glass is almost all. Fire-heat is used either not at all or only just enough to prevent actual freezing. For perfection of growth, the leaves not drawn and the flowers not flimsy—Daffodils should never be forced—it is surprising how far they will outstrip their open-ground brethren by a mere exclusion of frost. My nostrum for successful cultivation can be put into few words. Plant in August in loam, leaf-mould, and burnt earth in equal proportions, never using larger than 7-inch pots. Plunge in ashes until the shoots appear, then keep in cold frames, the foliage close to the glass, until the buds are almost opening. For the pots I am inclined to apologise. Once

The pleasure prepared in this little glass shelter, while the great outdoor Daffodil hosts are hanging back only *pour mieux sauter* presently with a rush, is twofold. First, there is this same close and affectionate florist's study of the points of the nobler individual blossoms—we can set each in the best light and at the best height. Every lover of Daffodils has been taught by plantations on steep banks and by cut bloom on a mantel-shelf that they look best on or about the eye-line. We can turn each to learn its features in profile, three-quarter and full face. Here are seven great ivory-white flowers of *Mme. de Graaff* in one small pot. Their ample rolling back at the brim, as though she were lavish enough of her robe's costly material to give it an extra fold, is a sure sign of vigour. There need be no fear of growing quite precious bulbs in this fashion, for with the simplest craft of management they will be as happy next year in the open ground as if they had never left it. The secret lies in protection of every leaf from injury after flowering and plentiful watering until they turn yellow. There is ceruus, smaller, but scarcely less lovely than *Mme. de Graaff*. In texture and tone its solid, drooping flowers are suggestive of some white stone of jade-like consistency. The *Leedsii* kinds are no less beautiful under glass

than the white Trumpets, but the least tall of these, as also of the coloured *incomparabilis*, should be chosen for this use. Leedsii Mimie Hume has a purity it never attains to out of doors white, except the faintest possible tint in its fringed cup of a colour like the pale side of a Peach. The large, shallow crown of *incomparabilis* Princess Mary shows the same suffusion of rare cinnamon-orange which it draws from the salt breezes of Scilly, but entirely lacks in my garden. Here is the new bicolor Victoria, wonderful in size and substance, a flower which seems quite to demand glass for development and clearing of its complexion. The glorious *maximus*, a Daffodil of pure wild blood, neither touched nor superseded by the florist's hand, revels in the moist air of its glass cage, and its great flanged golden cups continue to swell for a fortnight after their first unfolding.

The second delight, though the first in order of time, is the flowering in perfection of those smaller, early wild Daffodils which too often fail out of doors, or are missed by reason of what my man calls "scandalous" weather. Few things are more exquisite than a pan of the frail white Hoop Petticoat, or that other *Corbularia* of luminous pale citron. The humble

stature of *N. minimus*, whose tiny flowers imitate in their variety nearly every form of the larger Trumpets, exposes it to battering and soil-splashing by every storm, and minor fares but little better. The little Pyrenean *moschatus* is most delightful of all to establish, and has a Nerine-like glitter as of diamond dust in the pure white of its throat. Certainly let all these be grown also in the borders on the chance of halcyon weather to beguile them with a counterfeit of their Spanish or Algerian homes. But meanwhile it is more comfortable to "gloat" over their perfections—to make use of my friend Mr. Ewbank's expressive verb—in the greenhouse than outside with apparatus of bell-glass and mackintosh.

Here is *pallidus praecox*, no two of its flowers alike, but all taking on, in the calm of this retreat, a more refined refinement of their delicate tints of creamy straw. There are *Tazettas* but enough is as good as a feast, and to-morrow when we open the door the air shall be as of mid-April.

GEORGE ENGLEHEART.

AN ARTIST'S NOTE-BOOK.

CLEMATIS INDIVISA LOBATA IN POTS.

THIS is one of the most useful of winter flowering plants. It is easily grown and blooms when flowers are scarce. When planted out in the greenhouse it often gets attacked by mildew, and then it is almost impossible to keep it in health for any long period. The best way to grow this plant is in pots, putting them in 10-inch or 12-inch ones, and using a good rich turfy loam with plenty of drainage. About the middle of May stand the plants out of doors in a good open situation, securing them well to stakes and keeping the long shoots well apart, as they are apt to get entangled. This causes unnecessary trouble in the autumn. When taken into the greenhouse during the summer I give the plants a liberal supply of manure water with a little soot. This helps them considerably. By the end of October the plants will be covered with clusters of flower-buds, and they are then taken into the greenhouse, carefully trained to the rafters, and if given a little warmth, by the first week in January they will be a sheet of lovely white flowers, with the leaves of a dark green colour and quite free from mildew. After flowering, keep the house as cool as possible, and never allow the plants to be neglected. This Clematis is well worth all the labour that can be bestowed upon it. T. B. FIELD.

Ashwellthorpe Hall, Norwich.

[The accompanying illustration was made from a plant in Messrs. Wm. Paul's nursery at Waltham Cross. A group of this beautiful flower was shown by this firm at a recent meeting of the Royal Horticultural Society.—Ebs.]

SAXIFRAGA BURSERIANA.

HINTS ON ITS CULTURE.

IN the autumn of 1894 I obtained good plants of this beautiful Saxifrage and of its variety *S. B. major*. Both flowered freely in the early spring of 1895, and the extreme delicacy and grace of their white cup-shaped blooms made one feel that they were worth all possible care and attention.

But for a long time after this first success I met nothing but disappointment. Both plants were near the top of a bank, formed by cutting a V-shaped trench to provide shelter for hardy Ferns.

CLEMATIS INDIVISA LOBATA.
(From a drawing by H. G. Moon.)

They enjoyed the sun morning and evening during most of the year, but in winter the evening sun did not reach them, and they never had sun in the middle of the day. My first attempts to bring back the flowers were confined to carefully dividing the plants and to altering their positions upon the same bank. It seems certain now that the blooms of 1895 were due to the fine condition in which the plants were received. But at first I attributed them to the suitability of the position, and was unwilling to change. It was not till the spring of 1899 that I gave up the hope of flowers without some radical alteration, and moved the plants to an entirely different situation. In two respects the new position differs from the old. The Saxifrages now get no evening sun, but they are fully exposed from early morning to mid-day. They have the advantage of a deep, well-drained bed filled with loam, made light by a liberal proportion of mortar and sand. At the back are rocks, and stones are freely distributed over the surface to prevent evaporation.

It so happened that I paid a long visit to the rock garden at Kew last August, and devoted special attention to the Saxifrages. It was comforting to learn that even there *S. Burseriana* had proved a very shy bloomer, and a helpful hint was gleaned by noticing that the spaces between the plants were thickly covered with a layer of small stones. When I next saw my own plants it was plain that their new quarters had already effected a change for the better. With good hope I applied the stone mulch I had learned at Kew, and eagerly awaited the results.

This time there has been no disappointment. Before the hard weather, which commenced a fortnight ago and has broken up to-day (Feb. 15), *S. B.* major was in full bud, and one or two blooms had opened. The frost and snow have bruised the open flower, but the buds are not only not injured, but they have developed considerably while out of sight under the snow. *S. Burseriana* itself is not nearly so far advanced, but it too is forming flower-buds and is full of promise.

Until my plants have been a year or two in their new position I cannot claim to have reached any assured results; but I think I have found their secret in full exposure, good drainage, light soil, and a stone mulch.

BOOKS.

THE EARTH LIFE.

IN the star-embellished halls of the world, let none deem that he is poor while he takes to himself the heritage of the ages, and moves like a king in royal participation of the earth life, breathing its breath exhaled from grass and foliage, with the blood of Roses pulsing in his veins."

Of all things Nature is sufficient to itself, and man is either a reverent worshipper or an impudent and ignorant meddler in all life's higher mysteries. All the old nations had respect for the bounty of food, clothing, and the beauty of Mother Earth, ages before cultured Greece bowed the knee to Demeter.

To love and reverence the earth lies as it were at the very deepest root of material things, and in this little book one may find oneself "watching at the floating veils of illusion that shimmer in the spray of waterfalls and in glamorous tree-tops quivering between us and the sun." In its dainty pages "One seeks the thing behind, and sees the world grow strangely filmy and transparent with unreality, in the midst of which one stands, a naked

soul gazing silently from edge to edge of manifestation, over the beautiful waves of phenomena to that which is beauty itself." We listen to the great herons in the sunlit Scots Firs, and see the lights and shadows o'er the flat bogs of Erin, and again we see the flash of Daffodils in the grassy meadows, and breathe the fragrance of wild Roses and Wood Hyacinths ever fresh and fair.

The book throughout is an exquisite collection of poems in prose, and one finds deep rich notes struck in life's music now reminding us of Wordsworth or again of Walt Whitman, but always delicate and tender and true.

The contents consist of ten short chapters under the titles of Fir Needles, Bog Pictures, The Music Making, The Voice of the Sycam, Virginian Creeper, The River Beyond the Mountains, Winter's Trees, A Creeper of the Earth, In Autumn Weather, and Finis. All are most suggestive and charming, but they should be read under shady trees or in the garden during a summer holiday of ample leisure and peace.

The scenes appear to be mostly laid in Ireland and Wales, but the spring, summer, and autumn aspects of tree and flower life touched upon will appeal to all those interested in gardens or in wild Nature anywhere. In the chapter on Winter's Trees we are told that "winter is the long Lenten fast of trees." Again, of "Weeping Birches with branches fine as a maiden's hair, and nun-like in their sweet melancholy keep vigil, perchance say gentle masses, over the graves of thrushes grown tired of play; golden was the hair of the Birches but a short time since, but now it is turned all grey with that watching and weeping in the cold starshine." Speaking of perfume we are told that "In an October twilight the air seemed charged with ghostly fragrances that arise and move wistfully to and fro; these are the souls of flowers but lately dead, come back to look for their petalled dwellings. For the scent of a flower is its little soul, differing from another even as the souls of men; and as for these blossoms that are scentless, one must pity and be very tender, perhaps one day they shall have found a perfume." Once again, "In the scent of Mignonette there is all the sweetness and all the sadness of life," and even when cold and snow have done their worst in garden, wood, and field, yet still there is hope. "Nature in her love chooses ever to take away weary things to rest deep-hidden for a time, to mingle one with the other for building up a newer life. Thus the bodies of trees and of men shall lay them down all brotherly together in their common mother-soil, and the colours of October leaves shall blend once more with the sunlit tints in unborn hair; thus the wild-rose flush which we have loved may but pass to brighten again in June hedges; for the joy of these unborn may glow inside tropic shells or throb across the dove colour of opals; it shall perchance deepen the blush of a future dawn, or the latest rosiest flush over snow peaks, after the sun has gone down. And so it comes forth in everlasting renewal, in the gladness of youth, this pulsing life of the body that is miscalled mortal, moving fair limbs in fullness of health and vigour, sparkling in laughter and smiling through its own April tears, to pass onwards for ever and for ever in ceaseless interchanging and blending with other forms."

Here is a little bit on form *versus* colour that will appeal to many readers: "The relations to

the mind of colour and of form are of so diverse a nature; colour seizes upon the floating emotions and entralls them, but it is a higher part of the consciousness that recognises form; its appreciation necessitates in part the intellectual. The savage who gazes with rapture at a glare of scarlet perceives not the Gothic lines of his own tree colonnades; the colour forces itself by its so evident beauties upon the unmotivated mind, but the loveliness of form is a quieter and a less apparent thing, which must be sought by the finer understanding."

In a word, "Earth Life" is a little book that will set the quiet reader thinking on many of the subtle mysteries of Nature as they exist in garden and field for all who have eyes to see and a mind alert to recognise the importance of apparent trifles, the nebula out of which all things delightful are made.

F. W. B.

The weather. A Weybridge correspondent, writing on February 27, says: "In many respects the weather this month has been very unusual. The rainfall has amounted to 4.59 inches. Snow fell on the 2nd inst., and did not entirely

SAXIFRAGA BURSERIANA MAJOR.
(Drawn at Kew by H. G. Moon.)

melt until February 19. The snow which fell on the 2nd and 13th insts., when melted yielded respectively 1.22 inches and 0.68 inch of snow water. A cold thaw set in on the 15th, and half an inch of rain fell. In the frozen state of the ground it was impossible for the water to run away; hence the Wey and the Thames became in a state of flood. The Wey burst its banks at 11 p.m. on the 16th, rose higher than within living memory, broke the Plough Bridge at Byfleet, and did other considerable damage. The record for sunshine amounted to 35 hours 20 minutes, registered on fourteen days.

Eranthis cilicica (Schott & Kotschy).

Towards the end of last autumn I received from a nurseryman at Haarlem a couple of dozen tubers of a plant under the above name, which he described in his catalogue as being larger and finer than *E. hyemalis* (the well-known Winter Aconite) and very early blooming. These are only now coming into flower about the end of February, so that, compared with *E. hyemalis*, which blooms early in January, they cannot be said to fulfil their promise of extreme earliness. They are apparently very tree-blooming, as, though the tubers were by no means large, every one of them is producing one or more flowers. The flowers are of a fine bright shade of yellow and of a good cupped form, and make an exceedingly pretty edging to a small bed in the spring garden, where perhaps their coming as a succession to the common kind may by many be considered an advantage. W. E. GUMBERTON.

"The Earth Life. By E. Longworth Dimes. London: George Redway, 1899.

GARDENING OF THE WEEK.

KITCHEN GARDEN.

SOWING SEEDS.

WITH the break up of the frost, seed sowing in the southern parts of the country will need to be considered. Of course it is early for this work on a large scale, but, on the other hand, it is well to make a start with such crops as the small early Radishes, Spinach, Lettuce, Turnips, and Carrots.

CARROTS

take a longer time to germinate than many other vegetables; they should have a warm border for the first crop in the open, sowing such kinds as Early Nantes or Sutton's Early Gem.

TURNIPS

should be sown in small quantities for an early supply, using such kinds as Extra Early Milan or White Gem, the latter being of rapid growth, oblong in shape, and of great value for early supplies, as it does not run to seed in heavy soils as do some of the flatter roots sown early.

RADISHES

need so little soil as a cover when sown, that the land will soon be ready for this crop, and a warm sunny border will be suitable. The Earliest of All Radish is a remarkably quick grower with a very small top. There is no lack of good kinds such as the Forcing Turnip varieties and French Breakfast. Growth is assisted by covering the seed bed at night or in cold weather with long dry litter or bracken. The Carter Spinach is a very early variety, and sown now on a south border will give good dishes at the end of May. Sow thinly and in good soil.

PARSNIPS

The most approved mode of culture is to sow as early in the year as possible, so as to obtain a long season's growth, and it is advisable to do so as soon as the soil is in a workable condition. For exhibition roots large size is considered needful, and it is important that the roots be shapely, and though there are but few varieties, and those mostly good, the best flavoured root is doubtless the new Tender and True, which is not so large as the older kinds, but the quality is excellent, and the root is of perfect shape and much whiter in colour than others. This vegetable is not always a favourite, but in hard winters it is valuable. For late supplies, that is from February to April, we sow much later than is often advised; the roots grown thus are smaller, but I think they are more serviceable, as they are not so strongly flavoured, and, being quite hardy, may be left in their growing quarters and lifted as required. If desired, they may be dug and clamped in the open, as it spoils the roots to house or store in a dry or warm place. For large roots the Student and Hollow Crown are reliable. They need ample room—15 inches to 18 inches between the rows and half that distance between the plants.

G. WYTHES.

Syon House Gardens, Beaufort.

FRUIT GARDEN.

VINERIES.

ACTIVITY must prevail from now onwards throughout this section of the forcing department. In the early vinery, as soon as the setting period is past, reduce the number of bunches on each Vine rod to a fair crop, *i.e.*, as many as each Vine can bring up to perfection in the size and colour of the berries without unduly taxing it. The number of bunches left should depend on the size they promise to be; young Vines produce larger bunches and a greater weight of fruit than do older ones, and early forced Vines cannot carry so great a weight of fruit as those started later in the season. Thin the berries by the time they have attained the size of Radish seeds. This is tedious work and requires carefully doing, so as not to damage or dirty the remaining berries. The amount of thinning required depends upon the variety, and whether the berries will be large when

ripe or not. Black Hamburgh may be made thinner than Foster's Seedling, and Madresfield Court more so than either on account of the closer habit of the bunch. All berries should have room to swell so that they are not wedged together when ripe, and yet they should be sufficiently close for the bunch, when cut and lying on a dish, to retain its natural shape. Berries may be left much closer on the top shoulders than on the lower part of the bunch, as they are so arranged that they fall back towards the main stem, which they hide more or less and give the bunch a compact, finished appearance. Clip out the small berries, leaving the largest. With these proper fertilisation has probably taken place, and the largest at this stage will be the same when ripe.

The temperatures may range from 65° by night to 75° during the day, with a rise of 10° from sun-heat. Ventilate cautiously to maintain a growing atmosphere without creating an inrush of large currents of cold air. Close early in the afternoon so as to shut in the sun-heat, and when the weather is mild put on a crack of ventilation at dusk to remain on for the night. Ventilate at the apex of the vinery only at this season. Once a day may suffice when it is dull for damping all bare surfaces, while four times is not too many when the sun is shining, particularly if the nights are frosty. Go over the Vines as often as once a week to pinch back laterals.

In the case of Vines in flower, a drier atmosphere is favourable to free setting. Maintain this by increasing the amount of warmth in the pipes and giving more ventilation. Every day about noon give each Vine rod a few sharp raps with the hand, which will have the effect of fertilising the flowers. Damp only on very fine days, and then in the afternoon.

Disbud Vines lately started as soon as it can be seen which shoots show fruit, leaving shoots that show good bunches and those nearest the base of the spurs. This applies where only one shoot is required from each spur. Where the latter are further apart on the rods two shoots may be required; in this case leave the one that shows the best bunch and the other nearest the base.

When the shoots have grown to one or two leaves beyond the bunch, nip out the point; whether one, two, or even three leaves beyond depends on the distance between the rods, but guard against crowding the foliage. Prevent the shoots getting damaged in growing against the glass of the roof by drawing them partly down to the trellis, more or less according to the strength of the shoot, and finally tying them to the trellis when they have reached a tougher stage. Suitable temperatures for Vines with young shoots beginning to grow are about 55° at night and 60° in the day, gradually increasing them as growth advances until the flowering stage and the temperatures mentioned above are reached. Damp down as often as circumstances demand.

Start late Vines into growth by closing the ventilators and applying heat to keep up a night temperature of 50°. Take advantage of the assistance of sun-heat by closing early, and syringe the rods once or twice daily until growth is on the move.

Examine the soil of borders, and where it is approaching dryness afford a liberal supply of tepid water, giving it when the soil is less dry where the fruit is swelling, but guard against watering while in flower by doing it a week beforehand.

INDOOR GARDEN.

FERNS.

FEBRUARY is a good month in which to pot or replant the various Ferns, as they will then make their growth in the various receptacles, be they pots in an ordinary house or pockets in a rockery, to which they are transferred. The immediate effect of filling up blanks in rockeries at this time of year may not be so good as may be had by planting specimens in full growth later on, but the latter results are better in all ways. When planting Ferns for effect it is well to mix with them some of the hardiest of the Rex Begonias, the propagation of these being simplicity itself, as single leaves taken off with an inch or 2 inches of

stem, which may be pushed into a little soil in any available fissure, root freely and form plants from the base of the leaf, such plants being more compact than those which have been struck elsewhere and potted up in the meanwhile. The Selaginellas, too, should be attended to, replanting where necessary short pieces of the growth tips, thus getting rid of the older stems, the decay of which often causes the whole growth to fog off. Many of the Adiantums which are to be used for pot work may have all the growth cut away before splitting them up or repotting them in larger sized pots. This would be bad for many things, but the closer-growing Adiantums of the emacium type appear to grow away all the more freely for the cutting, provided it is done before many of the new fronds get into a forward state. For almost all Ferns a mixture of half fibrous loam and half good peat, mixed with enough sand to keep the whole free and open, will be suitable, but for the delicate rooted kinds some finely broken brick and charcoal mixed in as well will be found useful.

HIPPEASTRUMS

will now be pushing their flower-spikes, and those which are showing must be brought out from their winter quarters and stood on the stages in a light house. They may be grown very well under ordinary treatment for garden purposes without using plunging beds, the only difference in treatment being that plants so grown should be potted after they have flowered instead of potting them while dormant in mid-winter. Keep up a nice genial atmosphere in the house, which may be kept at a minimum temperature ranging from 55° to 65°, according to the time when flowers are wanted to be at their best. The plants should stand on a moist bottom and not on the open lattice stages with which houses are frequently furnished.

CARNATIONS.

The early autumn-struck batches of Malmaison Carnations should contain many plants that ought now to be potted on, using 5-inch pots for the majority, though the very strongest may go into 6-inch pots. The backward ones should be left undisturbed for a few weeks longer, as nothing is gained by potting on before the plants are ready. Early-struck winter-flowering Carnations may be removed from the propagating house and hardened slightly to prepare them for potting.

ANTHURIUMS.

Root action will now be getting very active, and as Anthuriums of the Scherzerianum section are mostly surface-rooting, it is advisable to add a little fresh material in the shape of fibrous peat and loam, interspersed with some lumps of charcoal and here and there a little Sphagnum Moss. The spathes now showing freely make it necessary to increase the water supply to the roots, but in this individual plants will vary greatly, according to their activity of growth.

FLOWER GARDEN.

PRUNING ROSES.

THE pruning of Roses should now soon be taken in hand; indeed, in mild seasons in the south-west the end of February is none too soon for commencing this operation. Amateurs as a rule prefer that their plants should produce a plentiful supply of flowers rather than a few show blooms for the exhibition table, and therefore need not prune so hard as is necessary where production of the latter is the object in view. All bush Roses should have the dead wood and spindly growths in the centre cut away; weak shoots should be shortened to half their length, while the stronger may be allowed to retain two-thirds of their growth. In the case of some specially weak growers harder pruning is advisable, since they lack sufficient vigour of constitution to perfect a quantity of bloom, and it is therefore necessary to direct what energy they possess to a limited amount of growth. Strong-growing Roses, such as those generally employed for covering walls and trellises, should, in the majority of cases, have had the greater part of the flowering wood cut out after it had perfected its crop of flowers in the preceding summer in

order that its place might be taken by the strong shoots thrown up during the season, which come into bearing the following year. This cutting out is, of course, unnecessary where the wall or trellis is but meagrely clothed, as in such a case ample room is afforded for the young growths to be laid in amongst the old without undue crowding. Some Roses, such as Rêve d'Or, should be but sparingly pruned, the growths being re-arranged and laid in as far as possible instead of being cut out, since extensive pruning encourages growth at the expense of flowers.

PROPAGATING SUMMER FLOWERS.

Many decorative plants that are indispensable for brightening the flower garden during the summer and autumn months, but which are of insufficient hardiness to exist during the winter in the borders, are usefully propagated during the early spring. Of these, tuberous Begonias occupy a foremost place. Seed should be sown in well-drained pans of light, porous compost surfaced with finely sifted sand and leaf-mould, the seed being sprinkled on the top of the soil. A pane of glass should be placed over the pan, and this kept in a temperature of 65°. The handsome Camas may also be raised from seed, which should be soaked for twenty-four hours in tepid water and then sown in light, porous soil in a temperature of 85°.

Seeds of plants useful for sub-tropical beds, such as *Acacia lophantha*, certain of the *Solanums*, *Eucalyptus globulus*, *Zea Mays variegata*, *Ricinus Gibsonii*, and like subjects, may also be sown in heat, while *Petunias*, *Verbenas*, *Marguerite Carnations*, *Campanula pyramidalis*, and other showy border plants may be propagated from seed, *Dahlias* of the *Cactus* and decorative sections, to which our autumn gardens owe their chief brilliancy, may be increased by placing the tuberous roots in heat, removing the young shoots when a few inches long with a little heel and potting them up, growing them on in heat and planting out in the early summer. Another plant that well repays, by the depth of its colouring, any little labour involved in increasing the stock is *Salvia patens*, whose beautiful blue is scarcely rivalled by that of the *Gentian*. This may be propagated in the same manner as recommended for the *Dahlias*, the young growths starting from the old roots making good plants for putting out if taken off and grown on in heat, while the roots eventually form more shoots in the place of those taken off. This plant may also be increased by sowing seed in heat at the present time.

S. W. F.

ORCHIDS.

MILTONTIA VEXILLARIA.

THE favourable change in the outside conditions has had considerable effect on the plants inside our Orchid houses, and much of the work which has been delayed will require early attention. The treatment of the above species, which I have found to be most successful, differs considerably from that which is generally adopted. The principal difference in the mode of culture is in the season of repotting the plants. The month of September is generally advised for this operation. I had been for many years under the impression that the autumn was not altogether the most suitable season for this operation, but, following the advice of those whom I considered more experienced than myself, I did not like to risk so radical a change as to defer repotting until the spring. When entering upon my present charge, the usual potting of this species had not been done, and I had thus an opportunity of putting my own ideas into practice, and my method has proved in every way satisfactory. It will be found that the principal rooting season of *M. vexillaria* is at the time when the new pseudo-bulb is about to be formed. If carefully observed, new roots will be found to be forming in quantity all around the base of the new growth. This is the best indication that the potting season has arrived, and should receive attention before the roots have become too far advanced, or they are liable to be injured in the operation of repotting. If done at this stage the new roots quickly establish themselves in the new material, and no ill-effects are experienced when the flowering season arrives.

Our plants are more forward than usual this season, and the roots being freely emitted, they are now receiving attention.

The potting compost should be of a very light nature: we use two parts chopped living *Sphagnum Moss* to one part fibrous peat. The pots should be just sufficiently large to contain the plant comfortably without crowding the old roots, and should be two-thirds filled with clean broken crocks. Shake the plants out of their old pots and carefully remove the old potting material. Cut away all dead roots from the base of the old bulbs. The newly developing growths are usually produced from the axils of the lower leaves at the base of the preceding season's growth. These leaves which ensheath the new growth generally decay when or just before rooting commences, and in case they have not decayed, and are likely to imprison the roots and interfere with their action, they should be removed, at the same time taking care to remove all dead and decaying matter that may be about the base of the plants. Take care that the base of the new growth is raised level with the rim of the pot, press the material moderately firm and slightly mounded towards the centre. After repotting give a thorough watering with rain water, using a moderately coarse rose on the water-can. Arrange the plants in position so that they may be placed within reasonable distance of the glass to prevent weakening the growths through being drawn. Shade carefully from direct sun-rays in bright weather until the plants become re-established, when more liberal treatment may be afforded, and as soon as the flower spikes make their appearance an abundant supply of moisture is required at the roots. The night temperature now should not be allowed to fall below 55°. Keep the house moderately close for a few days after repotting, but when the roots get hold of the compost, free ventilation may be afforded as soon as the temperature reaches 58°.

The atmosphere in bright weather should be liberally charged with moisture, the damping being done sufficiently early to permit the moisture to evaporate before evening.

The smaller growing section which flower later in the season do not commence rooting usually before April, and their repotting may be postponed until then. The lovely *M. v. superba* belongs to this section, also *M. v. Leopoldii*. These should not be disturbed until root action commences, but more liberal treatment as regards moisture at the roots should be afforded. Place the last-named varieties in a position near the glass. I find that they do best when suspended. H. J. CHAPMAN.

ZENOBIA SPECIOSA.

OF the large class of hardy flowering shrubs, broadly known as *Andromeda*, and for the most part natives of North America, none are more

beautiful than the subject of the illustration and its near relative, *Z. pulverulenta*; and no flowering shrubs of modest growth are more desirable, where garden ground or, still better, wild garden spaces present conditions favourable to their well-being. They thrive in moist, peaty earth, and accord most pleasantly with the wild Heaths, Whortleberry and Mosses that in such soils form the natural undergrowth.

The flower of *Zenobia speciosa* is a handsome spike, more fully set with the waxy white bells than perhaps any other of the *Andromedas*, and the individual bells are of more solid texture. This beautiful shrub is also known as *Andromeda cassinifolia*, and is one of the most distinct and charming of the entire race.

ZENOBIA SPECIOSA.

THE FLOWER GARDEN.

HARDY PLANTS IN POTS.

IT has always been a mystery to me why some amateur does not take up the cultivation of early-flowering hardy plants in pots and show us what they are capable of doing. Year after year we see many of our choicest gems struggling against frost, snow, and torrents of rain, such as we are now experiencing, or icy blasts and parching drought such as we have suffered from in recent springs. As long as they do not absolutely die we let them fight it out with the elements, and in most years lose a great part, if not all, of their beauty.

The late Mr. Atkins, of Painswick, who was my first pupil in horticulture, and who

knew how to grow hardy plants as well as any man I have ever known, often said that if people would give the same time and skill to hardy plants as they do to Orchids or florists' flowers, they would often be better rewarded; and though many of them want considerable experience to grow them well in pots, they are worth the trouble. I never knew the real beauty of *Anemone Pulsatilla*, an indigenous plant here, till I potted a good plant raised from seed. There must have been 150 flowers all out at once in a 10-inch pot and far finer flowers than usual. *Saxifraga Stracheyi*, *S. ligulata*, *Primula denticulata* and other Himalayan and Japanese plants, such as *Epimedium macranthum*, are far more interesting and beautiful ornaments for the house at this season than the everlasting round of Hyacinths, Tulips, Cinerarias, and Primulas, which too often fill the greater part of our greenhouses. *Corbularia alba*, *Tecophylla cyanocrocea*, and many of the smaller and more delicate spring bulbs are also excellent pot plants when properly managed. I shall be glad if anyone can tell me how to manage the fine varieties of Japanese Iris in pots. I cannot grow them out of doors, but have not yet discovered whether they can be grown in pots of moderate size.

H. J. EWES.

Colesborne, Gloucestershire.

THE CARNATION.

A NOTED florist writes to me about the Carnation. By the word "florist" I mean an amateur who cultivates the favourite garden flowers such as the Auricula, Tulip, Pink, Carnation, &c. The Carnation, to the florist, includes the bizarres, flakes, and Picotees; these my good friend terms the classic forms. My friend's words are important as showing the mind of the true old florist on this question. He writes, "I could not bear to grow any but the classic forms that make the flower to me. I do not think that these could ever vie in border effect with the selfs and the fancies perhaps, but then the object of the two divisions is different. In the olden time we did not grow for borderings and clumpings, and other devices that were at their best afar off. Our delight was in the intrinsic separate properties of each single flower." The old florists (and there are many not so very old) have a standard of excellence for the Carnation and Picotee. The Carnation, whether it be a bizarre or flake, must come up to this standard. The ground must be pure white, and if a scarlet bizarre, the colours are scarlet and maroon laid on in flakes and stripes. The crimson bizarre has also two colours, crimson and purple on a white ground. The pink bizarres are pink and purple. The flakes have a white ground marked with one colour only; they are of three colours, purple, scarlet, and rose. The Picotees have also a pure white ground with the petals margined with red, purple, rose or scarlet. The above defines the florist's type of a Carnation. Of course the flower must be of good form, the petals broad and of good substance, a smooth, not a serrated margin, and the flowers holding up their heads boldly on stout stems. This was an important point in the early half of the present century, and a burst calyx was a disqualification.

The late Mr. E. S. Dodwell, a keen Carnation fancier, informed me that he was one of the first amateurs who suggested showing dressed flowers on cards. I am not sure about the date, but it must have been about the year 1850, earlier rather than later. Before that time the stem of the Carnation was inserted in a long slender tube and stood up boldly above the mouth of the tube, and in this condition it was placed on the exhibition table. The National Carnation and Picotee Society has, amongst other good things, provided classes for Carnations shown as they are cut from the plants; moreover, it has improved on the old system of showing by putting the foliage of the Carnation with the flowers. They are, of course, still exhibited as heretofore on cards, and many persons think that the flakes and bizarres are most effective

in this way. Certainly the beautiful markings of these lovely Carnations are shown to the best advantage on cards. I am well aware that many amateurs do not like to see cards used with Carnations at all, but that is no reason why they should not be so exhibited now, as they have certainly been for half a century.

Carnation growers are now preparing to repot their plants, or to plant them in the open ground. The soil should be prepared and be in good condition before potting. The flower-pots also should be clean and dry. Sufficient drainage of potsherds should be placed in the bottom of the pots, and over the drainage some turf fibre to prevent the finer particles of soil from mixing with the drainage. A very good compost for Carnations consists of good fibrous loam, and if the loam is what may be termed sandy loam, do not add any sand, but a little mortar rubbish and a sixth part of leaf-mould. Pounded oyster shells may be used in small quantities, say a quart to a barrow-load of compost. It is desirable to pot firmly. Even in making a remark of this kind one is not always clearly understood. I instructed one of my men to pot the Carnations firmly, and he pounded the soil so much that the plants were forced out of the soil. Amateurs entirely ignorant of gardening matters often take up the culture of Carnations, and although they may read papers written in THE GARDEN and elsewhere for their instruction, it is easy to make a mistake owing to lack of practical knowledge. One of the most instructive writers on gardening matters was the late Mr. Thomas Baines, and he gave instructions in one of his papers as to the quantity of artificial manure to place on the surface of a 15-inch pot as a stimulant. It is well known amongst gardeners that this is a flower-pot 15 inches in diameter, inside measure, but Mr. Baines informed me that an amateur who attended to his own plants had followed his advice, and complained that the dressing had killed his plants. He had measured round the outside of the flower-pot under the rim, and used the amount of manure recommended to surface-dress a 4½ inch pot. It is easy for an amateur to write to the editor for advice when any detail is not well understood rather than to risk failure by following out instructions in the wrong way. After the plants are repotted they may be put into the garden frames again for a few weeks. If frames are not available, they may at once be placed out in the open garden, but in that case it would be better not to repot them until the middle of March, or even April. Being the owner of a large collection, the repotting of the plants extends over a considerable period, and I continue repotting well into May, but the late potted plants do not produce layers so freely as those done early.

The Carnation as a border plant is held in high estimation in most gardens, and many of us exclaim with Perdita, "The fairest flowers of the garden are our Carnations." Like the Rose, the Carnation is a good old English flower, and charms us with its sweetness and beauty. It deserves one of the best positions in the garden, and when well cultivated never fails to give satisfaction as a hardy border plant. It likes a rich deep soil and the careful hand of the gardener. Some people say their soil is not adapted to the culture of Carnations. I can only reply that I have cultivated the Carnation in all classes of soil, and never failed to grow the plants well. In light gravelly soil in a dry district the plants need attention as to watering in summer, and the layers should be put down as soon as they are ready. It is easy also to get a little good loam of a clayey nature to mix with the light soil—a spadeful would be sufficient for two or three plants. I prefer to plant three or two spadefuls of suitable yellow loam placed around the roots will form an ample root run for the three plants for one season. This, of course, is not necessary unless the soil is unsuitable. In soil adapted to Carnations nothing is needed except deep working of the soil to a depth of 18 inches or 2 feet. In new soil this depth has to be reached gradually by digging or forking up the subsoil without throwing it on the surface. If manure is plentiful, some of it may be mixed in with this subsoil. For the last six or

seven years I have been breaking up fresh soil in this way: the system answers admirably for Carnations and all classes of flowers, fruits, and vegetables that relish a generous deep soil. The ground has been under grass for generations, and we line off an opening for the trenching 2 feet 6 inches wide; a good spit is taken out and all the loose earth; the bottom is then well dug up, so that with the top spit and the loose earth taken out this digging loosens the soil to the depth of 18 inches, but the bottom part is left at the bottom, and if some good manure is mixed up with it the roots work freely into it. If this lower 8 inches were put on the top and what was previously the surface turned to the bottom, a failure of the crop the first year would be the result. Trench as deep as you can, but work the subsoil into the upper portion gradually, that is a few inches each time of trenching. It is always safe to put a few handfuls of potting soil around the roots of each plant, pressing it down firmly. Three plants together in a border have a better effect than one. For borders and clumps selfs are best. By the use of this class a mass of crimson, purple, or bluish purple (as in Bendigo), scarlet, rose (deep or pale), yellow, buff, white, bluish, &c., is obtained. I do not think any of the striped, flaked, or edged flowers should be planted in masses, but as individual plants, or three together, in borders to be admired, as for their beauty and sweetness they are unsurpassed.

Before this paper appears in print it will be time to sow Carnation and Picotee seed. March is the best month, as under careful treatment every plant will produce masses of bloom the following season, that is in 1901. Sow in a little heat, prick the seedlings out in boxes, and they are ready to plant out in May or June. It is also the time for repotting, and here, as in the border, the best effect is obtained by three plants in a pot 8½ inches in diameter. In the flower-pots a size smaller two plants will be enough, unless they be small, when three may be put in. I may finish this too lengthy paper with a few hints about tree or winter-flowering Carnations. Get the cuttings or slips in as early as possible. Now is the time to strike the plants in order that flowers may be obtained at Christmas. The cuttings should be given a little bottom-heat, and the temperature of the propagating house should be about 55°, certainly not less than 50°. The cuttings form nice rooted plants in about three weeks, when they may be removed from the propagating frame and be inured to a more airy house. Pot off singly into small flower-pots, and as the plants increase in size and vigour repot when necessary. The plants produce the best blooms in 6-inch flower-pots. J. DOUGLAS.

NICOTIANA SYLVESTRIS.

IN comparatively few of the numerous seed lists which reach me at this time of year do I find this recently introduced *Nicotiana*. How it comes that a plant of this importance, alike valuable for the sub-tropical garden and hardy border, should receive tardy recognition I am at a loss to understand. It was shown at least twice last year at meetings of the Royal Horticultural Society, and received an award of merit. Unlike *Nicotiana glauca*, this plant produces large heads of bloom which remain open all day. I would advise all who want a distinct new plant not to fail to order a packet of seed this spring.

J. T. BENNETT-POLL.

SOME OF THE RARER SHRUBS AND CLIMBERS.

As my text is about "flowering shrubs and climbing plants," I think I must next say a word about *Abutilon vitifolium*, which takes high rank wherever it does well. I have two varieties of it, and both were given to me by the late Major Gaisford. So far it has done quite well in my garden, though I fear it is not very long lived, and certainly it needs protection when the weather is cold. Mr. Nicholson says in his "Dictionary" that it is not a fast

grower, but he does not live in the Isle of Wight, for here I think it responds to the conditions under which it is growing very quickly indeed. It considerably overtops the wall against which it is placed, and it would reach to a greater height still if it were not for the wind. For the rest of my "flowering shrubs and climbing plants" I think names must in a great measure suffice. Magnolias should never be forgotten where objects of great interest are desired, and the following may be recommended with safety: *M. conspicua*, from China, which grows to a great size, and is a very handsome hardy deciduous tree; *M. Soulangiana*, which is probably a hybrid between *M. conspicua* and

southern garden. It is a pretty Australian composite, and its small whitish Aster-like flowers make it look as though it were all covered over with snow in the month of July. Several Roses are of course to be recommended. *Rosa gigantea* seems to be worthy of its name, though it has not been so kind to me in the way of flowering as it is to its possessors in Cannes. *Rosa sinica* is too recent an introduction for me to speak about it with any certainty as of use in the Isle of Wight. All that I can say is that it seems to be passing through this winter successfully, and if it does half as well here as I saw it performing last spring in the south of France I shall be glad that I have it.

years against a wall with a western exposure. It grew to such a large size and did so well from every point of view, that Mr. Noble, of Ascot, who happened to see it, declared that it must be the finest in the kingdom. But its end was a miserable one. I noticed one very hot day, either in July or August, that the sap was exuding from the stem and trickling down in rather plentiful streams; the leaves were also beginning to curl up, and "unhappiness" was written on my shrub in a very evident manner. In a very few days it was all over with it, and smstroke had done its work beyond all chance of repairing. As I have no wall in my garden with an eastern exposure, I planted another

CLIMBERS UPON THE OLD ABBEY WALL, BATTLE, NEAR HASTINGS.

M. obovata, *M. stellata*, from China, *M. Lemnii*, which is a hybrid and has large flowers of a rosy-purple colour; and *M. parviflora*, from Japan, which is certainly hardy in this part of the world and a great favourite of mine.

Piptanthus nepalensis is a sort of evergreen Laburnum with bright glossy green leaves and abundance of showy flowers. *Carpenteria californica* must not be passed over; when in bloom the pure white flowers, resembling those of the Japanese Anemone, render it of great beauty. *Caryopteris mastacanthus*, from China, is certainly of great value because of the late season of the year when it is accustomed to blossom. *Ozothamnus rosmarinifolius*, though rather tender, should have a place in any

Vitis Coignetiae and *Vitis humulifolia* are both included in this place. The former for its vividly bright red foliage in autumn; the latter for its very pretty berries, which are of a pale china-blue colour and marked all over with dark specks.

Of course the above do not comprise anything like the number of flowering shrubs which can be recommended for a warm part of the world, and there are many others besides them, but I think those which I have named are amongst the best I possess, and the others may be taken for granted. Let me just mention two that have done well here for a long time, but which, alas! are now lost to me. I had a very fine specimen of *Fremontia californica* for many

years against the vestry of St. John's Church, and this seemed to prosper for a time, but its fate was as bad as its predecessor's, though in quite a different manner. I did not return from the Continent last year till April had come, and my gardener becoming impatient uncovered the shrub before the east winds had departed; it was stricken by a cold blast, and very soon perished. Still, I feel sure that under more favourable circumstances I could pilot *Fremontia californica* through all its difficulties, and that it would again do well in my hands. It should never be exposed to a western sun in the Isle of Wight, and must be protected against strong east winds while it is young. There is another fine shrub which is much hardier than

GUMMING ON FRUIT TREES.

WHAT is known as gumming on fruit trees is practically confined to those producing stone fruit. Peaches, Nectarines, Plums, Apricots, Cherries, and Almonds are all prone to it, and the intelligent cultivator dreads its appearance on the trees named almost as much as an outbreak of canker in the Apple orchard. Fortunately, however, it does not spread rapidly from tree to tree as canker does, though it is equally difficult to eradicate when once it puts in an appearance. Is gumming really contagious? Some authorities aver that it is so, and that the exudation contains spores of a fungus which under certain conditions increase rapidly, and do not remain on one tree. So far, our experience does not lead to this conclusion, as we have known one Peach tree badly attacked for years, while the adjoining tree whose branches met those of the diseased one remained perfectly free.

Its appearance at times is most puzzling, even to experienced growers, as, knowing what conditions are likely to produce gumming, measures are taken to avoid or combat it. This is not so, however, with the amateur or young gardener. The latter especially often undertakes the management of a valuable lot of trees either growing against walls in the open or under glass. A few errors on his

afforded as the trees require it. Deep rich borders of loose formation and overcharged with manure encourage soft strong shoots which seldom become matured by autumn. With outdoor trees such unmaturing wood is easily injured by frost, and its effect is readily noticed the following spring, first of all by the discoloration of the bark, forming patches of red here and there. These eventually turn black, the bark dies, and this is generally followed by the exudation of gum. From this it would appear that the sap vessels having been ruptured, strangulation at that point results, and the growth above, being cut off from further support, perishes. With strong growing trees then we would advise that they be lifted and the roots re-arranged, bringing the latter nearer the surface. Place fresh strong loam about them, the only addition required being old mortar, and then ram the whole firm.

Although, as pointed out, gumming may be the result in the first instance of indifferent root action, coupled with what may be termed frost-bite, it generally follows wounds or abrasions of the bark. How do these abrasions occur? Seeing the evil which follows, how careful one should be in avoiding them.

A perfectly trained tree always reflects credit on

is generally supposed, and which deserves a word of mention in this place. I refer to *Lagerstromia indica*, which is lost to me through my own fault. Some years ago I was paying a visit to Major Gaisford at Offington, and of course I inspected the garden with the greatest attention and care. He said to me, "Come along here and I will show you something with which I am sure you will be pleased." He then took me into the little inner garden, where so many treasures were kept, and there he pointed out a fine specimen of *Lagerstromia indica* which was in full blossom at the time. Unfortunately, I was far from being pleased with what I saw. The shrub was delightful and quite worthy of his strongest commendation, but I saw in a minute that I might have had just the same in this garden if I had not been so impatient about it. *Lagerstromia indica* had been in Major Gaisford's hands for a long time before it blossomed, and so it had been in mine, and to all appearance it was doing very well indeed. Perhaps it might have blossomed the very next year if I had not cut it down and thrown it away. It was a lesson to me which I have never forgotten, that I should not despair about shrubs. Canon Ellacombe says something of this in *THE GARDEN* of February 10 about *Clerodendron trichotomum*. *Lagerstromia indica* is a beautiful object, and Mr. Robinson writes in his book on greenhouse and stove plants that it is quite different in appearance from any other plant with which he is acquainted.

I have just taken a run round my garden, and I see there are still several other things which deserve a word of mention by me, but they must be taken for granted. Let me only give just a few names. *Indigofera decora*, *Pterostyrax hispidum*, *Abelia rupestris*, *Exochorda grandiflora*, *Berberis stenophylla*, *Lonicera fragrantissima*, *Lapageria alba* and *rosa*, *Rhynchospermum jasmoides*, *Desmodium penduliforme*, *Choisya ternata*, &c.

St. John's, Ryde, I. of W. H. EWANK.

EVIL EFFECTS OF WIRE AND TIGHT SHREDS.

part in the cultural details may lead to much trouble, it not the total loss of valuable trees, through the excessive exudation of gum from the main stem or branches. As many will be employed for the next few weeks in the important work of pruning and training these fruit trees, a few remarks bearing upon some of the causes of the evil referred to may prove useful.

We say "some" of the causes, because it is certainly not confined to one. Among others, one of the most fruitful sources is the too free use of the knife. Trees which produce stone fruit resent hard pruning more than either the Apple or Pear. Under proper treatment pruning can and should be reduced to a minimum. This in the first instance is accomplished by properly disbudding the branches, and secondly by preventing the formation of gross shoots. Rank-growing trees are more subject to gumming than those which make medium growth and carry full crops of fruit annually. To severely prune the former only makes matters worse. The fault can generally be traced to the border, unless through some mishap the crop fails, and there is not the strain of fruit production to balance growth. It is the roots, therefore, and not the branches that must be dealt with. A firm and rather shallow rooting medium favours the formation of short-jointed, healthy fruiting wood, support being

the man in charge, and young gardeners generally take a pardonable pride in such interesting work; but in securing some of the branches in the desired position a certain amount of strain is necessary, and it is here that the utmost care must be taken to avoid undue pressure on any part sufficient to damage the bark. A wound to the latter is easily produced by the use of shreds that are too short, and which will not allow for the free swelling of the various shoots for at least a year. No part of the tree should ever be allowed to press hard against the brickwork. Young trees should always be planted so that the base of the stem is at least 6 inches from the wall;

then should any of the main branches or any portion of the stem, owing to curves or bends, come too near the bricks, they should have the bark protected by placing a wedge of cork where the pressure exists. Many condemn the use of strained wire on walls for training purposes, as the wire and the eyes or studs through which it is laced prove so harmful to the bark. In these gardens there is something like a quarter of a mile run of Peach walls, of which half is furnished with wires, and for the rest we use shreds and nails for training the trees. We cannot say that any difference has been noticed, or that gumming has proved more troublesome with one or the other method, but the greatest care is used in training. The matting or tar cord is twisted round the wire before the shoot or branch is tied in position, and it is the aim of the workman to place the ties alternately on either side of the shoots, the same as one would do with shreds and nails. By this means the growths can be straightened and the strain is on the matting, as the bark is not pressed against the wire, while the loop is of sufficient size to allow of the wood swelling. Even then it is necessary to look over the trees frequently during the growing season to free any shoot that is likely to become too closely encircled by the shreds or matting.

THE FRUIT GARDEN.

APPLE BESS POOL.

THIS is a very old kind, and one not often met with, but it has much to recommend it, especially where good late Apples are in demand. It is excellent for cooking, or may be used for dessert.

The fruit is long and pointed, above average size, and deep red. After being kept for some time it turns a yellowish red, and is in use from February to April. Its greatest fault is that it is a shy bearer in a young state, but those planting an orchard will be wise to plant two or three trees of this kind. It is an upright grower, and when it comes into bearing, crops enormously. Some thirty years ago there used to be some fine trees in an orchard at Hedson Park, Maidenhead. Has anyone tried this grafted on the broad-leaved Paradise stock? J. Crook.

PLUM POND'S SEEDLING.

This is a fine useful kind, and when in full bearing the crop is most profitable, as it commands a ready sale in good condition when placed on the market. This, as well as Victoria, does grandly on north walls, and frequently here escapes frost, while it is destroyed in other positions or on trees in the open. This I saw an example of last September when paying a visit to Sherbrook Park, Exeter. On a high wall, 14 feet or 16 feet high, were growing two large trees, which were covered with large fruit. J. C.

Chard

The usual wall nail, we consider, when it comes in contact with the bark is equally as injurious as the galvanised wire, perhaps more so, as the edges of the former are sharp, and soon make an indentation in the swelling bark. Neatness in training is requisite, but the health of the trees must be studied also; therefore sufficiently large shreds should not be discarded for those which are just large enough at the time, but which do not allow for future development of the branches they hold in position. The accompanying drawing shows the evil result of the latter and a fruitful source of gumming.

RICHARD PARKER.

Goodwood.

CORRESPONDENCE.

CYCLAMEN COUM.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—"H. H. D.'s" note (p. 96) on the successful culture of *Cyclamen coum* in a sunny border is interesting, as affording evidence of the adaptability of this charming flower and its varied forms to positions situated in full sunlight, provided conditions of soil and drainage are satisfactory. The inference apparently drawn by "H. H. D." is, that his fortunate experience is due to the baking received by the corms from the summer sun, but, from the numerous instances that might be recorded where this plant flourishes in more or less shaded situations, it is to be surmised that full exposure to the sun's rays is by no means the chief element of success. In the note referred to, in mentioning the profusion of self-sown seedlings which have sprung up in the neighbourhood of the parent corms, your correspondent alludes to the seeds that have been carried into the shrubbery behind the narrow, sunny border, from which spot corms are being constantly dug up for friends. Here, at all events, there must be shade, which the plants, from their rapid increase, evidently find as congenial as full exposure to the sun. I have met with instances where *Cyclamen coum*, *C. nepapolitanum*, and others have seeded themselves freely in sites shadowed by trees, and were surrounded by hosts of immature plants. The chief desiderata for the successful culture of hardy *Cyclamens* are, doubtless, perfect drainage, a porous soil and shelter from bitter gales, which by tearing off the leafage weaken the corms, and, given these conditions, it would appear immaterial whether they are planted in the full sun or in partial shade.

S. W. F.

MAKING AN ASPARAGUS BED.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—I shall be much obliged if you can furnish me with a few hints as to laying down an Asparagus bed. I have two old beds about 30 feet long by 5 feet wide which I propose to plant with fresh roots. Can you advise me as to when I should plant the roots, approximately how many I should require, and generally as to the course to pursue in planting?

Norwich. W. S. TILLET.

[We fear that you will get poor results by patching old Asparagus beds, as the result from such is never satisfactory. The soil must be partially exhausted and the plants or seeds would not have a fair chance. You could fill up gaps with seed, or you may, as you have two old beds, lift one to patch up the other, but by so doing you will probably injure the old roots in the bed, and the roots lifted will not be nearly so good as younger ones in new soil or position. Your best plan would be to plant a new bed entirely, then in a year or two at the most you may destroy the old beds. If you have the means to force in a frame or a house, the roots from the old beds would do for that purpose, and afterwards may be thrown away. If you have no convenience for forcing, we advise you to cut hard for the next two seasons whilst your new bed or beds are making good progress, and then destroy the old ones, using the land for a totally different crop for a time. There is no

time to lose in making the land suitable by deep cultivation and manuring. By making the beds now, the soil will be in better condition to plant or sow early in April. We would in your case advise plants for the making of new beds, as you will thus gain a season's growth, as seeds do not make much progress the first year, and you cannot cut from seedlings till the third year, and only then very sparingly. The beds are best made in an open position and in light soil. This should be deeply trenched, and the land will need ample quantities of decayed manure, well mixed in as the work proceeds. In good loamy soil double-digging will suffice, the bottom being dug up and the manure being placed under the first course. In heavy land we would advise a liberal use of old mortar rubble, burnt refuse, sea sand, or charcoal refuse—in fact, anything that lightens and improves or drains the soil. For the latter purpose a liberal use of rubble or the rougher materials advised above will be found beneficial if this is placed in the bottom of the trench as the work proceeds.

Planting is best done early in April just before the root growth is active. In a 30 feet run of bed, 15 to 18 inches between the plants would be none too much, and the same distance between the rows. We prefer even more space if room is no object, but frequently in small gardens much room cannot be afforded. We have had good results by planting 12 inches apart in the row, with 18 inches between the rows. In light land the beds are best made level, not raised, but in heavy or wet soil the beds should be 6 inches above the alleys. These latter should not be less than 2 feet wide. In planting, draw out wide flat drills, spread out the roots evenly, and cover with fine, good soil. Plant 4 to 6 inches deep, and should dry weather follow, give water and mulch between the rows with short manure to conserve the moisture. We prefer two-year-old seedlings, and these, if purchased, should not be out of the soil long or allowed to dry. No cutting should be done the first year, and very little the second. If seed is sown, sow at the same time as advised for planting, thin early, and feed in both cases as growth is made.]

FLORAL CLOCK.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I may refer "A. K." to the "Philosophie Botanica" of Limbous (ed. iv., 1809, p. 415). That is the original of all floral clocks, and if "A. K." does not know the book, he will thank me for introducing him to a work which, in my opinion, has more good information on botany in a small compass than any book I know.

H. ELLACOMBE.

Biton Viarage, Bristol.

ON THE WILD FLORENTINE TULIPS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In answer to "T. R." (p. 150), at least nine distinct species of Tulip grow wild in the neighbourhood of Florence, viz.: *T. Oculus solis*, *T. precox*, *T. maleolens*, *T. Fransoniiana*, *T. Clusiana*, *T. stragulata*, *T. spatulata*, *T. sylvestris*, *T. australis*. Whether they are all truly native there may be doubted. Some of them (*e.g.*, *T. Clusiana*, *sylvestris*, and *australis*) show very little variation. Some of them show a great deal. On plate 1990 of the *Botanical Register* are figured four well-marked varieties of *T. stragulata*. Whether *T. spatulata* is a wild Italian plant or a variety of the long-cultivated and very variable Siberian *T. Gesneriana* is doubtful. Several very distinct forms of Tulip commonly cultivated in gardens are nowhere known in a wild state. The whole subject of Florentine Tulips has been fully discussed by Dr. Lérrier in his paper entitled "L'Origine des Tulipes de la Savoie et de l'Italie," published at Turin in 1884, and in a paper entitled "Les Tulipes de l'Europe," published in the 14th volume of the bulletin of the Society of Natural Science at Neuchâtel. He has also written other papers on the same subject. The whole question of the relationship to one another of the different Tulips is a very difficult one. Not long ago Mr. H. J. Elwes, F.R.S., discussed it fully in a paper read before the Royal Horticultural Society and pub-

lished in their journal, and I have since done my best to monograph the genus, in the journal of the Linnean Society and the *Gardeners' Chronicle*.

J. G. BAKER.

BUCK-BEAN.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—It has occurred to me to write you about a flowering water plant which I saw growing wild in the country last summer. It seems to be a species of Water Lily, and blooms about midsummer. It has triple leaves, somewhat like the Strawberry plant, but smooth and glossy green. The flower-spikes resemble very much those of the Horse Chestnut tree, and are almost exactly like it both in colour and form.

I have a very small fountain in the grounds of this club, the lower basin being 4 feet or 5 feet in diameter and nearly 3 feet deep, containing gold fish. Do you think I might try to grow a clump of those flowers in it? If so, what would be the best way to manage them, and the proper time to attend to the planting? The garden space is well open, and gets a good share of sunshine in summer and autumn.

P. F. O'REILLY.

St. Iver's Club, Wexford, Ireland.

[The plant you describe is the Buck-bean or Marsh Trefoil (*Menyanthes trifoliata*). It is not a Water Lily, but a member of the Gentian tribe. Like others of the Gentianaceae, the root is intensely bitter and a valuable tonic. It grows in mud covered with shallow water or peaty swamps, and is not suitable for growing in a deep basin. If the tank has an overflow that could be led into a cemented space a foot or so deep, a suitable place could there be prepared for it. It should be planted in autumn. Eds.]

VERONICA SPICATA.

[TO THE EDITOR OF "THE GARDEN."]

SIR, This beautiful little alpine is, I believe, almost unknown in English gardens, except by those who have brought it from its own mountain haunts, from the fact, mentioned in the note in THE GARDEN, February 17, page 130, that an altogether distinct and common species is credited wrongly with its name. It is plainly to be identified by the description in M. Correvon's very useful and popular little book, "Flore colorée de poche"; nevertheless, it was wholly a revelation to me last year to find it not more than 3 inches or 4 inches high, growing on grassy ledges on the mountains above the Rhone valley, and always finer and bluer when the drip of the rock above made the soil somewhat damp and spongy, which bears out "T. J. W.'s" theory that it does best in moist soil. Having grown the tall garden *V. spicata* and discarded it as taking the room of more desirable species, I puzzled a good deal over this dainty little alpine, and was very glad to have the difficulty solved by his note. The true *V. spicata* has the advantage of lasting in flower for a considerable length of time, for we found it in July, and a few stray spikes still remained in September when we left the mountains. The little colonies of bright blue spikes, scarcely higher than the turf from which they sprang, will always live in memory amongst the many lovely pictures of plant grouping which we found amongst the rocks. Once I gathered a solitary pink specimen, but never again met with one. Though it evidently enjoys moisture, *V. spicata* will succeed in drier spots; indeed, M. Correvon gives it as growing in dry pastures, where it is certainly abundant. We found it in company with *Dianthus sylvestris*, one of the most charming of alpine Pinks, and with the deeper coloured and clustered *D. atrorubens*.

K. L. D.

[Is it possible that in this case, as in some others, that those who have brought plants from the Alps may have observed that what in higher altitudes is a dwarf plant degenerates into a lanky, weedy thing in our gardens? We have seen this happen in the case of the common field Ox-eye Daisy, flowering only a few inches high at about 4000 feet, and to all appearance a charming dwarf alpine plant, but gradually growing in a garden to its usual stature. Also a

very neat and showy Echinum from a mountain district in Norway grew from seed in an English garden into a dull plant of straggling habit, not to be compared with our native Viper's Bugloss. It is unlikely that this is actually the case with regard to the Veronica in question, for were it so, the fact would be sure to be known to M. Corveon, and probably also to so excellent a gardener as "K. L. D." But it is worth mentioning in anticipatory mitigation of the occasional disappointment of the ardent collector. In illustration of the same natural law as affecting some plants, we may mention that seeds of a true strain of the dwarf Papaver alpinum grown for three years in English gardens produce plants that increase in size till they are not to be distinguished from P. nudicaule. —Eps.]

THE BEST PEAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—As I have the following sorts of Peas, could you kindly tell me through THE GARDEN which sorts to sow and how often to keep up a succession: Ringleader, Fillbasket, Antocrat, Main-crop Marrow, Ne Plus Ultra? YOUNG GARDENER.

[As regards dates of sowing, a given date cannot always be advised, for this reason, seasons vary very much; for instance, if cold or wet, a much longer period of growth is needed, and if hot and dry, the plant is soon affected and cropping over. The following is a safe plan: Sow seed every three weeks from now until the end of June or early in July. Begin with Ringleader, which should be ready early in June. Fillbasket will follow on if seed is sown at the end of March and be ready at the end of June. Antocrat sown the middle of April should be ready in the early part of July and last until the third week. Main-crop Marrow sown the end of April or early in May will provide a succession of pods well into August, and it has few equals as a good summer Pea. Your last selection, Ne Plus Ultra, cannot well be beaten. Seed sown of this in June should give you good produce early in September. If you need a longer supply, sow Michaelmas Pea at the end of June for late September use. On the other hand, the best calculations may be upset by climatic influences; to guard against this, provide deep drills and an ample supply of rotten manure for the three late lots. Your selection is excellent, and you should not fail with these. —Eps.]

DEEP CULTIVATION.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Having read in your paper the excellent article by Mr. Beckett on "Trenching the Soil," also the interesting and instructive correspondence arising therefrom, I should like, with your permission, to say a few words.

Ten years ago the writer worked under Mr. Beckett at Aldenham House for nearly three years, and so had facilities for observing the working of the soils in the kitchen gardens, and also the new ground work then, as at the present time, being extensively carried on. I can fully endorse all Mr. Beckett and your other able correspondents say in favour of trenching, both as regards the excellence and uniformity of the crops at Aldenham. During the two years I have been in charge of the gardens here I have always, whenever possible, carried out this same system of trenching. Although only about a mile from Aldenham House, the character of the soil differs very considerably. Here we have a very sandy soil, while in many places within 2 feet or 3 feet of the surface there is pure white sand of a very fine nature. After being here a few weeks I took in an extra piece of land for vegetable growing, trenching it 3 feet deep and working in a good dressing of manure. The crops we have had from it have well repaid the trouble taken with it. Potatoes were very clean, while I may mention that Brassicas were quite free from clubbing, a trouble which in my opinion we should hear much less of if trenching were carried out. Mr. Engleheart mentions the case of the allotment holders who had excellent crops obtained from the ordinary digging, while the deep cultivation system

on the adjoining land was a failure. I may mention that I know of a labourer living in this parish who three or four years ago obtained a piece of meadow land, about 10 poles, for an allotment, and who trenches it every year. The land is very heavy, having a clay subsoil. He has had first prize for his allotment at Aldenham show for two years, while last year he obtained the bronze medal given by the Royal Horticultural Society for the neatest and best cultivated allotment, following this up by obtaining seven firsts, two seconds, and one third, out of eleven entries at the One-and-All show held at the Crystal Palace a few weeks after.

H. NAVLOR.

The Gardens, Piggotts Manor, Elstree.

NARCISSUS PALLIDUS PRÆCOX.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—In Mr. Arnott's note on the above Daffodil he alludes to the difficulties that so often attend its culture in some gardens. In many instances that have come under my own notice this variety has persistently died out, though re-introduced again and again and planted in varied soils and exposures. In light soil, in heavy loam, and in the grass its behaviour has proved equally unsatisfactory. The first season it blooms fairly well, the second poorly, and rarely shows more than an occasional flower in the third year. As mentioned by Mr. Arnott and by "F. H. C." (p. 49), this Daffodil is very variable. Some strains doubtless possess a stronger constitution than others. In my own case the only one that appears to possess any constitutional vigour bears a flower the pale yellow of which is suffused with a suspicion of buff, while the petals are of greater consistency than is the rule in the majority of forms. It is to be regretted that this beautiful Daffodil is not amenable to universal successful culture, since its elaste colouring and earliness render it invaluable in the garden. S. W. F.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

LATE blooming varieties will produce a wealth of flowers during midwinter, some of these lasting well through February. For supplying cut bloom for Christmas and the New Year festivities, I know of nothing more beautiful or more easily produced. Indeed, from a gardener's point of view, this section is probably the most serviceable of any, either as bush plants for the conservatory or for use in a cut state.

Good cuttings should now be procured and rooted five or six in a 3-inch pot. Little heat should be afforded them at this season, giving only just sufficient to keep them in a fresh condition. Put off singly into 3-inch pots immediately they are sufficiently rooted and grow on in a cold frame.

Among the best varieties to grow for this purpose are Jessica, in my opinion, the best of all the many whites; L. Canning, Niveum, Boule de Neige, white; Princess Blanche, creamy white; Golden Gem, bronzy yellow; Eugène Lanjaulet, bright golden Anemone pompon; Jeanette Sheahan, light yellow sport from the well-known Princess Blanche; Rubra perfecta, purplish crimson; Perle des Beantes, crimson; King of the Plumes and Mrs. Filkins, both golden yellow, belonging to the feathery class, most useful for this season, but will require to be stopped rather late to retard their flowering. Early-flowering varieties should now be propagated. For beautifying the flower garden during the autumn these have few equals. When grouped together in separate colours in flower beds, dotted about in the shrubbery borders, or arranged in their proper heights and blending their colours so as to harmonise on a border wide enough to contain three or four rows, and this, I think, is the most suitable and pleasing position to cultivate them they are objects of much beauty, and a few degrees of frost do not hurt them, for after the Dahlias

and other tender plants are killed these will continue to give much pleasure during the closing days of summer. These should also be struck five or six in 3-inch pots and kept close in a cold frame till rooted, when they may be potted off singly when sufficiently rooted, and planted out from these about the middle of May on richly-prepared ground. Twenty-four good varieties are as follows with their colours and approximate heights:—

Alice Butcher, red, shaded orange, 3½ feet; Bouquet Fen, terra-cotta, 3 feet; Crimson Précocé, crimson, 1½ feet; Crimson Pride, crimson, 2½ feet to 3 feet; General Hawkes, crimson-claret, 3 feet; Geo. Wermig, sulphur-yellow, 2½ feet; Gustave Grunerwald, light pink, 1½ feet; Harvest Home, bronzy red, tipped gold, 3 feet; Harvest Queen, ivory-white, 3½ feet; Henri Yvon, rosy salmon, 1½ feet; Ivy Stark, orange-yellow, 2½ feet; Lady Fitzwygram, white, 2 feet; Little Bob, crimson, 1½ feet; Louis Lemaire, rosy bronze, 1½ feet; Mme. A. Nonin, silvery pink, 4 feet; Mme. Desgrange, white, 2½ feet; Mme. Marie Masse, lilac-mauve, 2 feet; Mrs. J. P. Pitcher, blush, 2 feet; Mychett Beauty, golden yellow, 3 feet; Mychett White, pure white, 1½ feet; Piercy's Seedling, orange-yellow, 1½ feet; Queen of the Earlies, white, 3½ feet; Roi des Précoces, dark crimson, 3 feet; Rycroft Glory, golden yellow, 3 feet; White Grunerwald, white, 1½ feet.

E. BECKETT.

Aldenham House Gardens, Elstree, Herts.

RECENT PLANT PORTRAITS.

THE March number of the *Botanical Magazine* contains coloured portraits of the following five plants:—

Stanhopea Rodrigueziana (plate 7702), a native of New Grenada, is a handsome member of this most singular family of Orchids. The flowers, which are solitary, are so anomalous in character, that they cannot be compared with any other of the forty known species, and may almost be said to constitute a distinct section of the genus. The flower has a white ground heavily spotted with carmine, and the middle portion of the lip (or mesochile) bears no approach to anything hitherto known. This curious plant bloomed for the first time in 1898 in the collection of Sir Trevor Lawrence, Bt., at Burford, Dorset.

Mathiola sinuata var. *Ogrisia* (plate 7703), a native of Western France, is a fragrant annual or biennial Stock, with good-sized single flowers of the purest white. It is found in a wild state on the Ile d'Yeu (Insula Oya), off the coast of La Vendée, whence its specific name, which in gardens has been corrupted into ohienis and chinensis.

Ceropegia Waudii (plate 7704), a native of Natal, is a curious trailer with variegated foliage, pinkish stems, and inconspicuous tubular flowers of merely botanical interest.

Cereus mojavensis (plate 7705), a native of California, is also known under the synonyms of *C. Bigelovii*, *C. molliavensis*, and *Echinocereus mojavensis*. It is one of the dwarf tufted species nearly allied to *C. Fendleri* (*Botanical Magazine*, t. 6533), and has very long spines and medium-sized, rose-coloured flowers.

Kniphofia Rafii (plate 7706). A native of Natal. This is a pretty little new species of Kniphofia, nearly allied to *K. laxiflora*, from which it differs in its shorter smooth-edged leaves, shorter perianth, and exerted stamens. It is exceedingly free-growing, and was introduced into cultivation by Herr Max Leichtlin, of Baden-Baden.

The Paris *Revue Horticole* for February 16 has a portrait of a pretty and well-known hardy shrub named *Ribes speciosa* or *fuchsoides*, with flowers resembling a small Fuchsia. The number of the same periodical for March 1 gives a portrait of a new Hybrid Tea Rose named Sokel d'Or.

The *Revue de l'Horticulture Belge* for March contains plates of *Moradla didyma*, the well-known scarlet-flowered hardy border labiate allied to the *Salvia* family, and one of *Ledia Gouldiana*, a beautiful species, with medium-sized, rosy-purple flowers with white centre.

W. E. GUMBLETON.

INDOOR GARDEN.

PROPAGATING CODIÆUMS AND DRACÆNAS.

THERE are several methods of increasing these beautiful and indispensable stove plants, all of which are best performed in early spring. As *Codiaeums* and *Dracenas* become old they are apt to lose their lower leaves, especially if frequently employed for house decoration, and then become very unsightly, necessitating the propagation of young plants. It is unwise, however, to only do this when it becomes absolutely necessary, for small specimens in 4-inch or 5-inch pots are most serviceable for decorative purposes, and should, if possible, be raised every year. The most generally practised method of propagation is to partly cut through the stem at the point where it is desired that roots shall form, and to cover all around this with moss held in position by being tied with raffia. The moss requires to be frequently syringed to keep it moist, so as to encourage the formation of roots. As soon as these appear through the moss the rooted portion may be severed from the parent plant and potted in a 3-inch pot. For some few days after potting, until the roots have taken hold of the new soil around them, it is advisable to keep the plants in a close atmosphere, as is obtainable, for instance, under a handlight or bell-glass, in the stove.

It is not so necessary to partially cut the stems of *Dracenas*, for roots are more readily emitted from these than is the case with *Codiaeums*. Instead of allowing the shoots to form roots while still on the plant, they can be taken off to form cuttings and inserted in very small pots (filled with silver sand or a mixture of sand and peat) and plunged in the propagating pit. The cuttings will take root if simply placed in sand, providing that this is kept warm by hot-water pipes underneath and is enclosed above by a small frame. We prefer, however, to place them in small pots, taking care to make the soil firm around them. They will soon take root if the pots are plunged in a brisk bottom-heat under a hand-light in the propagating pit. If the old stems of *Dracenas* are laid in sand and kept warm by artificial heat, numerous shoots or suckers will be produced. These may be taken off, and usually root very readily; in fact, if not removed too soon they will probably already have made some few roots. *Croton* cuttings may also be made to take root in warm water if the temperatures of this and of the surrounding atmosphere are properly maintained.

In France, some cultivators, after having established the young plants by one of the above-mentioned methods, instead of transferring them by gradual stages from small pots to larger ones, plant them out upon a prepared bed of good soil made up in a warm house, preferably a low one, as then the plants are near the glass and obtain a full amount of the sunlight which is so necessary to their successful culture. They remain here during the summer months, are kept warm and moist to encourage growth, and when this is almost completed, in September they are taken from the bed and potted into various sized pots, according to the amount of roots they have made. By this method fine healthy plants are obtained in one season, and if carefully lifted and potted, no leaves will be lost. This, I think, is a more satisfactory method than that of keeping the plants in pots throughout the summer, for the growth made under the latter conditions is not so free, and the plants when well rooted are more liable to suffer from want of water than those planted out. If this occurs they experience a check, and probably lose some of their leaves. H. H. T.

VELTHEIMIA VIRIDIFOLIA.

This genus of half-hardy bulbous plants, belonging to the Lily family, comprises but three species, all of which are natives of South Africa. *V. viridifolia* bears, in the months of February and March, racemes of reddish-yellow flowers, borne on a stalk

from 12 inches to 18 inches long. They are very showy, and the plants also are of easy culture. We keep the bulbs during summer in a cool house facing north, and late in the autumn repot if necessary, or perhaps only top-dress them, using a rich soil with a good sprinkling of silver sand. The bulbs may remain in the same house until the flower-spikes begin to push if they are not required earlier than the end of February. Growth will soon commence after potting, and if the bulbs are of a proper vigour the flowers will eventually appear. Gentle stimulants can be applied with advantage when these are seen.

Frogmore, Windsor.

H. THOMAS.

GALTONIA CANDICANS.

AMONG the good garden plants of comparatively recent introduction scarcely any are more gener-

GALTONIA CANDICANS.

ally useful than this fine South African bulb. Unlike so many other bulbous plants from nearly the same latitudes, it needs no special care, such as drying off and replanting, but makes itself quite at home in our gardens, preferring soils that are stiff and rich.

It is a plant so distinct as well as important, that it deserves to be placed with special care; and although it is good anywhere and useful for carefully planned groups in the mixed flower border, it is best when so placed that it makes a quiet picture of flower beauty of its own. Of all positions the best would be as an isolated group, only associated with some rather important foliage of a different character, such as that of the large form of *Megasea cordifolia*, and so placed that it would be

against a background of quiet and yet darkly-rich greenery such as that of the clipped Yew hedge, where its ivory white bells and glaucous leaves would have their fullest value.

SOCIETIES.

THE ROYAL GARDENERS' ORPHAN FUND. THE NEW CHAIRMAN.

At a meeting of the committee of this fund, held on the 2nd inst., Mr. H. B. May, Dyson's Lane Nursery, Upper Edmonton, was unanimously elected chairman, in succession to Mr. William Marshall.

ROYAL HORTICULTURAL SOCIETY.

The next fruit and flower show of the Royal Horticultural Society will be held in the Drill Hall, James Street, Westminster, on Tuesday, March 13, 1-4 p.m.

A lecture on "The Evolution of Plants," illustrated by various garden strains coming true from seed, will be given at three o'clock by Mr. R. Irwin Lynch.

LINNEAN SOCIETY OF LONDON.

The following lectures will be given at the evening meeting, Thursday, March 15, at 8 p.m.: 1. "Report on the Botanical Results of an Expedition to Mount Roraima, in British Guiana, undertaken by Messrs. F. V. McCannell and J. J. Quelch," by Mr. W. Götting Hensley, F.R.S., F.L.S., and others. 2. "Bryozoa from Franz Josef Land, collected by Mr. Jackson, Harnsworth Expedition, 1896-97," by Mr. A. W. Waters, F.L.S., &c.

THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

The arrangements for the present year are somewhat more ambitious than any made of late years. The fruit, flower, and scientific committees instituted last year are continued, their *personnel* being scarcely altered. The usual shows in April and in September exhibit nothing novel in the schedules of prizes, the class for a decorated fruit-table, to be judged by points, though largely a failure in the two years it has formed an item in the autumn programme, forming this year again one of the principal classes in the schedule. Difficulties arising from confused ideas as to what constitutes "kinds" and "varieties" are dealt with in a series of paragraphs explaining what the society means by these terms, and exhaustive lists of dessert and culinary hardy fruits with synonyms of Grapes and Roses are given to serve as guides to exhibitors.

A new feature in the arrangements is provided by two smaller exhibitions to be held respectively on May 2 and July 11, at which, however, no prizes will be given. At the former meeting Mr. Lindsay is to lecture on "Primroses and their Allies"; Mr. Hugh Dickson, Belfast, at the latter to lecture on "Roses." The fruit and flower committees meet on the occasion of each of the shows.

BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY.

WE have received the annual report of this excellent society, and we are pleased to learn that the committee have to report a substantial increase in the subscribers' and members' subscriptions, which is especially gratifying, showing the popularity of the society is still maintained. On the other hand, the show receipts (excepting the summer show) are not so favourable, many causes contributing to the detriment of the Chrysanthemum show. The expenditure generally is less, and the committee are able to present a balance-sheet showing a profit on the year's working of £39 2s. 1d., and a balance in the hands of their bankers of £107 7s. 1d. The thanks of the society are due to the president, vice-presidents, and subscribers for their kind support during the past year, and to Mr. F. G. Clark for his services as hon. auditor. The following exhibitions will be held this year: Spring show, April 3 and 4; summer show, August 28 and 29; and Chrysanthemum show, November 6 and 7.

The president of the society is Mr. G. W. Willett, J.P., D.L.; chairman, Mr. G. Miles, Victoria Nurseries, Dyke Road, Brighton; vice-chairman, Mr. J. Binney, Danny Park, Hassoeks; hon. treasurer, Mr. W. Balchin; and secretary, Mr. J. Thorpe. In connection with this society there is a mutual improvement association, and an interesting course of lectures will be given during the spring by well-known horticulturists.

NATIONAL DAHLIA SOCIETY.

WE have received the report of this society for the past year, and we are pleased to notice that the annual exhibition at the Crystal Palace (on September 1 and 2) was very satisfactory.

The number of entries was again about 300. Omitting the blooms submitted for certificates and those staged "not for competition," the number of shows and fancies taken together was 1302, a decrease, as compared with the previous exhibition, of 108; of pompons 1880, an increase of 24; of cactus 1809, a decrease of 45; of singles 516, a decrease of 456; making a total of 5727 blooms, a decrease of 582.

The unfavourable season had adversely affected the show and fancy blooms, so that they were mostly deficient in the quality and symmetry which secure admiration for them; nevertheless, there were some fine individual blooms. The pompons were exhibited in very good form, small compact blooms of good quality being generally staged instead of the larger and coarser blooms that were once too often seen. The dry weather militated seriously against the display of singles, so that the competition was poor, several intending exhibitors failing to stage their blooms. Those that were staged presented the usual attractiveness and charm of the single varieties in a high degree. The display of Cactus

varieties was again magnificent, and received added interest on account of the large number of new kinds. They are evidently very popular, and are developing more rapidly than ever, so that the task of adjudicating on the respective merits of the many seedlings is rendered difficult. Certificates were awarded to sixteen new *Cactus* varieties.

The committee made arrangements to hold a meeting at the Royal Aquarium, Westminster, on September 19 and 20, for the purpose of affording an additional opportunity for the exhibition of seedling Dahlias, and for the awarding of the society's first-class certificate to such of the new varieties exhibited as the committee considered worthy.

In order to give additional interest to this meeting, it was thought desirable to offer prizes in a few competitive classes, and £26 was promised towards a special prize fund for this purpose.

The primary object of this, the first late exhibition of the society, was so well attained, that more than seventy seedlings were brought before the committee, and certificates awarded to ten of them. The competition in the various classes was very good, in a few severe, and such a large number of miscellaneous collections was got together that the whole formed quite a large show, the success of which was the subject of universal comment. The committee desires to thank Mr. R. Dean for the invaluable services rendered by him in connection with this show.

The value of Dahlias for decorative purposes has not yet been fully realised, and it is hoped that the society will be able to do more in the future than it has done in the past to illustrate the effectiveness of the Dahlia when used in this way. More classes should be provided having this object in view.

The methods of staging at present in vogue in most of the classes are admittedly far from ideal, and the committee would welcome any exhibits in illustration of fresh ways of staging or any suggestion that would improve the existing methods.

The committee desire to call attention to the periodical horticultural shows in connection with the Paris Exhibition of 1900. Classes will be provided for Dahlias on the following dates: August 21, September 11 and 25, and October 9, each show extending over a period of five days. Further particulars can be obtained from the Royal Commission, Paris Exhibition, 1900, St. Stephen's House, Westminster, London, S.W.

The committee desire to convey their best thanks to the donors of special prizes, viz., The Crystal Palace Company, Messrs. J. Cheal & Sons, Messrs. Keynes, Williams & Co., Messrs. Dobbie & Co., and Mr. W. Troseder; also to the Horticultural Club for kindly allowing the society's meetings to be held in the club room.

The committee are able to report that the membership has been well sustained during the year, but the numbers should be much greater than they are, and it is hoped that the society's supporters will in the coming year endeavour to bring the society to the notice of some of the many enthusiastic admirers of the Dahlia who are outside of the society and unaware of its existence.

The committee deeply regret to have to record the loss by death of one of the patrons of the society, Baron Ferdinand de Rothschild, M.P.

The committee has also to deplore the loss sustained through the death, in the prime of life, of their president, Mr. T. W. Girldstone, M.A., F.L.S., who was elected to the presidency in 1897 after serving the society as hon. secretary for nine years. In each of these offices Mr. Girldstone devoted himself enthusiastically to the interests of the society, and great things were expected as the result of his efforts in future years. During his brief tenure of office as president he had secured the addition of many names to the roll of membership, and the compilation of the official catalogue of Dahlias was almost entirely his own work. Mr. Girldstone's achievements as a raiser, grower, and exhibitor of single Dahlias are more fully dealt with on another page; by his untimely death the National Dahlia Society loses a most distinguished president and its most liberal supporter, and the horticultural world one of its most devoted and intelligent members.

In conclusion, the committee express the sincere hope that each member of the National Dahlia Society will make every effort to obtain the support of new members, in order that the work of the society may be extended and carried on to the best advantage.

The income of the society from all sources, including the balance of £1538. 9d. in the society's favour from the year 1898 and the sums contributed to provide prizes for competition at the second exhibition, amounted to £2004s. 9d., and the entire expenditure, including the payment of all prizes awarded at the two exhibitions, amounted to £1924s. 7d., leaving a balance in the treasurer's hands of £798s. 2d.

The hon. secretary is Mr. Frank Hindson, Gimmersbury House, Acton, W.

THE NURSERY AND SEED TRADE ASSOCIATION, LIMITED.

SALE OF WEED-KILLERS AND INSECTICIDES.

THE annual report of this association contains many matters relating to the trade, including sections of the Pharmacy Act under which proceedings have been instituted by the Pharmaceutical Society against nurserymen and seed merchants for selling by retail compounds for killing weeds and insects on plants. As the members present desired that the Pharmacy Act should be amended to permit of nursery and seed merchants selling these compounds, the subject was referred to the committee of management to consider and determine what steps should be taken in the matter, and to ask the assistance of the manufacturers of and wholesale dealers in these compounds in defraying the costs of and incidental to the preparation and passing of an Act of Parliament.

The president (Mr. N. S. Sherwood) expressed his opinion, and the members concurred that it was advisable that a fund should be raised to enable the association to take the

opinion of counsel upon questions affecting the trade, and to contest or support any action for their mutual benefit, as the annual subscriptions to the association are insufficient for this purpose after discharging the working expenses of the association.

It may interest our trade readers especially to know the names of those interested in this association. From the annual report we learn that the treasurer is Mr. W. J. Nutting (Messrs. Nutting and Sons), 106, Southwark Street, S.E. Trustees: Mr. H. Simpson (Messrs. Cooper, Taber and Co., Ltd.), 90 and 92, Southwark Street, S.E.; Mr. J. Hayes (Messrs. J. and J. Hayes), Edmonton; Mr. Harry J. Veitch (Messrs. James Veitch and Sons, Ltd.), Chelsea, Committee: Mr. G. H. Barr (Messrs. Barr and Son), 12, King Street, Covent Garden, W.C.; Mr. George Binyard, Maidstone; Mr. W. Y. Baker (The Thames Bank Iron Co.), Upper Ground Street, Blackfriars, S.E.; Mr. J. Harrison (Messrs. Harrison and Sons), Leicester; Mr. J. Hayes (Messrs. J. and J. Hayes), Edmonton; Mr. J. Ingram (Messrs. Wood and Ingram), Huntingdon; Mr. W. J. Jeffries (Messrs. Jeffries and Son), Cirencester; Mr. John A. Laing (Messrs. J. Laing and Sons), Forest Hill; Mr. William Paul (Messrs. W. Paul and Son), Waltham Cross, Herts.; Mr. T. Peed (Messrs. John Peed and Sons), Rompell Park Nurseries, West Norwood, Surrey; Mr. T. F. Rivers (Messrs. T. Rivers and Son), Sawbridgeforth; Mr. A. P. Silberrad (Messrs. R. Silberrad and Son), 25, Savage Gardens, Cuthbert Friars, London; Mr. H. Simpson (Messrs. Cooper, Taber and Co., Ltd.), 90, Southwark Street, London; Mr. J. B. Shade (Messrs. Protheroe and Morris), 68, Cheapside, London; Mr. Harry Turner, The Royal Nurseries, Slough, near Windsor; Mr. Harry J. Veitch (Messrs. J. Veitch and Sons, Ltd.), Chelsea; Mr. Wood (Messrs. Wood and Son), Wood Green, London; Mr. H. Williams (Messrs. H. S. Williams and Son), Upper Holloway, N., Secretary; Mr. J. P. Worrell, 30, Wood Street, Cheapside, E.C.

ANSWERS TO CORRESPONDENTS.

Names of fruit. *Weiss and Buntel*. The small Apple is Count of Wick, and the large one Gloria Mundi.

Names of plants. A. Y. Z., *Saxosa*. Probably you have not been answered before because you failed to send your proper name and address. The white flower is *Iris stylosa alba*, and the blue flower is *I. histrio*. Heath is *Erica mediterranea alba*. H. G. 1, *Croton Lehmannii*; 2, *C. Van Gerstedtii*; 3, *C. Cronstedtii*; 4, *C. nobilis*. The plant not numbered is *Draecena superba*.

TREES AND SHRUBS.

Shrubs to fringe a small pond (POMONA). Our correspondent asks for the names of shrubs suitable for planting on the margin of a small pond in Northern Somersetshire. We should advise (elder) Rose, whose original form is the wild Water Elder (*Sambucus racemosa*) of our stream-sides; also this same Water Elder, for the sake of its beautiful berries; hardy Bamboo (*B. Metake*), Quince, beautiful both in flower and fruit; and the North American Snowdrop tree (*Balaia tetraptera*), grown either as bush or standard. With such plants it would be well to associate such plants of bold aspect as the large herbaceous Spiræes, such as *S. Arvensis*, and the handsome *Rubus spectabilis*.

FLOWER GARDEN.

Seeding Verbenas (EVA). You can purchase Verberna seed now from any good seed firm at quite moderate prices both in distinct colours and in mixed form, some four to six diverse colours we have noted as being thus offered in packets separately. Seedling plants make very beautiful beds and cannot be termed formal ones, as when several colours intermingle, there is not only variety in colour, but in habit of growth. The seed should be sown thinly in shallow pans, that have in the bottoms ample drainage and are filled with sandy soil. It is well where seeds are few to make shallow holes equally all over the surface of the soil with the point of a finger and to put a seed into each, as in that way the little plants later get ample room to grow, and become quite strong before it is needful to dibble them off into other pans, or else shallow boxes, thinly, or to get them singly into small pots before planting them outdoors in May.

Dahlia shoots (S. M. G.). There is yet ample time to obtain cuttings from stored Dahlia roots. Set yours in shallow boxes close together and put some fine soil about them, then water and stand in very gentle warmth on the floor of a greenhouse for a week. As soon as the small shoots are seen to break up from the crowns of the roots place the boxes near the glass and give more warmth. In a very short time stout shoots 3 inches long will be formed. Take these off carefully with a sharp knife, each cutting having a small piece of fleshy root attached, insert them thickly into 5-inch pots filled with sandy soil, and stand them in a close, warm frame, or, failings such, then in a box stood in the greenhouse that can be close covered with glass. They will soon make root, and become, after being potted singly, nice strong plants in small pots ready to plant out at the end of May. The roots may then be divided with a sharp knife, each portion having one stout shoot, and these again may be planted out in due course.

INDOOR GARDEN.

Ivy-leaf Pelargoniums (AVLEFFE). You will observe that to the plants you term "Geraniums" we have given the proper appellation of Pelargoniums. Really they are not at all Geraniums. That these plants are largely employed, as you say, in summer bedding there can be no doubt, but if the soil be at all rich or the weather wet, they have a tendency to grow too luxuriantly and not to

flower freely. We prefer to see them planted against a trellis of from 3 feet to 4 feet in height, intermixed with white and red Fuchsias and free-growing Heliotropes, as in such case, just moderately tied to the trellis, they intermingle and form singularly beautiful objects. Also from such plants quite a wealth of flowers may be cut during the season. Ivy-leaf Pelargoniums also grown as semi-pyramids are most effective when in good-sized pots they are dropped into holes on lawns during the summer.

KITCHEN GARDEN.

Summer Spinach (S. J. W.). Very early sowings of Spinach will be useful this spring, as winter greens are fast becoming scarce. Anything of the Spinach type will be in great request. Sow now, and again three weeks hence, in shallow drills on a warm border, seed of the variety known as Flanders, or ordinary summer Spinach. These sowings will give plants in the rows rather thick, but the growth will be all the quicker, and then the crop may be clean cut as fast as high enough to do so. But for later sowings to give a summer supply, and these should be made in rows 12 inches apart monthly and quite thinly, sow the Long Stander, sometimes called The Carter. That fine variety produces large, thick leaves, and is much longer than is any other variety in bolting off to flower. For August sowings to stand the winter there is no better variety than is the Vinoflay, or, as sometimes called, Victoria.

Sowing Vegetable Marrow seed (HOPE).— Being a very tender plant, it is unwise to sow seed of it too early, except where it is possible to put plants out on to a manure bed and under a frame for a time, as then the plants come into fruiting early. For first-early purposes, and especially where grown under glass, the best varieties are the short-fruited Pen-y-hyd and the excellent Moore's Cream. But to grow, as is ordinarily done, on hills of soil or on heaps of decaying garden refuse for general fruiting, none are better than the Long White. To have good plants to put out at the end of May, sow seeds in a greenhouse or frame in 5-inch pots, four seeds in a pot, early in April, putting out all but two, when good growth results. Such plants after being well hardened by exposure in a sheltered place outdoors can be planted out where to grow with safety, or putting a little warm manure into a hole and a few inches of soil over it, a few seeds may in that way be sown outdoors late in April.

TRADE NOTE.

THE RATIONAL TREATMENT OF FUNGID DISEASES. UNDER this title we have before us a copy of a pamphlet, issued by Messrs. William Wood and Son, Limited, of Wood Green, N., the well-known horticultural merchants and specialists. Marking, as it does, a departure from the old methods of dealing with the fungoid pests of field and garden, the details of the treatment cannot but be of interest to all horticulturists and agriculturists.

Whether from the pamphlet that "preventive treatment" is the basis of the rational method, *i.e.*, purification of the soil and the destruction of hibernating spores which may be resting in it, thus ensuring for the roots healthy action and immunity from fungoid contagion. The soil being thus freed from impurity and disease germs, the environment of the young plants is favourable to vigorous growth. This purification is effected by means of a new discovery of this firm, which they have named "Veltha," and which is considered to be the most destructive fungicide known.

Prevention is always better than cure, and growers would do well to begin at the root of the matter by applying the fungicide even before there is visible evidence of the fungus. Certainly there is no more practical way of demonstrating the worth of an article than by the testimony of the users to its beneficial effects. Judging from the large number of letters which the firm have received giving strong evidence of the value of "Veltha" as a cure for and preventive of fungoid diseases, there should be a great future before the new remedy. We understand that Messrs. William Wood and Son, Limited, will be happy to supply copies of this pamphlet gratis and post free to inquirers.

GARDENING APPOINTMENTS.

MR. J. STORESBURY, late head gardener to Mr. George Pim, Brennanstown, Cabinteely, has been appointed head gardener to Colonel Smyth, Gaybrook, Mullingar.

MR. W. USHER, for the past three years general foreman at Brennanstown, succeeds Mr. Stodesimny as head gardener.

CATALOGUES RECEIVED.

FARM SEEDS. *Keat and Bendon, Darlington.*
Asparagus. *George Bonnard and Co., Maidstone, Kent.*
Herbaceous Plants. *F. Percival, Loughford, Warrington.*
Engineer Cycles. *The Engineer Cycle Works, Limited, York.*
Garden Seeds. *W. H. Hudson, 109, High Road, Kilburn, N.W.* *H. A. Burpee & Co., Philadelphia, U.S.A.*

THE GARDEN.

No. 1478.—Vol. LVII.]

[MARCH 17, 1900.

TO OUR READERS.

NOW that the renewed issue of *THE GARDEN* is already in the third month of its existence, we feel it to be no less than a duty of common courtesy to offer a few words of thankful acknowledgment to the many friends whose cordial co-operation may well be regarded as the main cause of its now steady growth and increasing usefulness.

The letters that went out to the paper's old friends, asking for a continuation or revival of their active support, have without exception been answered in a spirit of the most friendly encouragement, while the two or three who have excused themselves from special exertion on the plea of age, or ill-health, or of a burden of literary work already too heavy, have expressed their regret in such kindly terms, that we feel as sure of their sympathy as if they had been able to prove it by practical acquiescence.

We feel that it is no small matter of encouragement to be thus assured of the willing support of those eminent in botany and horticulture throughout our land, while we have also the distinguished satisfaction of receiving constant proofs of most generous kindness from our brothers in horticulture in foreign countries.

It is doubtful if there be any bond of common interest so fruitful of good-fellowship as that of gardening. The love of flowers induces a kind of freemasonry, so much so, that we often feel a need to relax some of those lesser restrictions of civilised intercourse to which we Britons are apt to attach a perhaps undue importance. For whereas we are notoriously shy of addressing ourselves to persons unknown to us, even in such exceptional circumstances as render this exaggerated reticence an absurdity, so does a love of flowers, and the simple and wholesome impulses it engenders, impel us to abandon our attitude of apprehensive isolation to cast off our defensive armour, and greet each other as simple human beings. Perfect strangers will write to one another, the ceremony of introduction being performed by some Daisy or Forget-me-not; and from such a beginning many a lifelong friendship has arisen.

Close is the natural bond between botany and horticulture; each needs the help of the other, and though a good gardener need not be a profound botanist, yet some knowledge of the broader classifications of plants and their

main relationships is not only a great addition to the interest of gardening, but is an important matter as a guide in cultivation. When, for instance, we say broadly that all Buttercups like strong heavy soil, it is understood that this applies not only to the more obvious Buttercups such as *Ranunculus*, *Caltha* and *Trollius*, but also to *Clematis*, *Anemone*, *Adonis*, *Helleborus*, *Eranthis*, and the other plants that come within the natural order *Ranunculaceae*. So also the fruit grower, if he has a garden favourable to Pears and Apples, will know that he can also succeed with Roses; and he will remember how closely linked are the many plants of the great Rose family that inhabit our gardens and woods and wild places; of how his Peaches, Plums and Apricots, Almonds and Cherries are all nearly related, and these with the Sloes and White Thorns of our hedges and the great wild Cherries of our high woods; of how Cherries are nearly related to Laurel and its kinds; how Raspberries and Blackberries are near akin; how Strawberries, Gemms and Potentillas resemble each other in flower and leaf; how Quinces, Medlars, Pears and Apples, Mountain Ash and Service tree, and all the wild and cultivated forms of *Spiraea* are all within the great Rose family, and love good loam as does the Rose itself. And for all such easy excursions into the fields of botanical knowledge and such aids to the groping of our ideas we have to thank the botanists, beginning with the great Linnæus.

And though much of botanical lore may be dry, or may appear so to those who have little knowledge of the chain of observation and record that have gone to the development of each separate conclusion, yet we may well be reverently thankful to those patient and learned men who have endured the toil needful for the gradual disentanglement of some of Nature's knotty problems, and have put the discovered facts before us in ways so clear and simple, that they can be easily followed by people of little learning.

While offering our thanks to all those whose constancy of helpfulness seems tacitly to promise a steadfast continuance, yet as we wish always to increase the usefulness of *THE GARDEN* and to further extend its wide embrace of matters of horticultural interest, so do we also invite the further co-operation of all whose tastes are reached by the subjects of the paper.

Those who have a love of flowers and gardening are widely spread throughout our immense empire; and now that whole families of the younger generation are growing up in

homes where an understanding of the better ways of gardening, that during the last quarter of a century have come to be understood, and are about to go forth into the ends of the earth as soldiers, sailors, and engineers, on missions diplomatic, religious or medical, on surveys, on duties of all kinds that take men into many parts of the temperate world, we ask them to remember the home gardens and to keep a bright look-out for anything that may help to enrich them.

To such correspondents the pages of *THE GARDEN* offer a cordial welcome for any short record of their observations, especially when these are gathered in such latitudes as may present some sort of equality of climate with our own.

We feel sure that the friends of *THE GARDEN* will learn with pleasure, and we trust with some measure of personal gratification, that the paper is increasing greatly in circulation, and this surely is a wholesome sign that the love of flowers is extending in these isles and in other lands, from whence most encouraging letters have been received to testify to this world-wide interest in gardens and horticulture generally.

HAMPSTEAD HEATH PROTECTION SOCIETY.

We are pleased to learn from the report of the third annual meeting of this society that its zeal in preserving the natural beauty of the famous Heath shows no abatement. This society has accomplished much good work in the past, and will ever watch that the picturesque features of the Heath are not destroyed by bad planting and the idiosyncrasies of local authorities.

In the course of the meeting, a short, formal report of which we give in the proper department, Mr. F. Danford Thomas mentioned "the unrivalled charm of wildness so near London. In his garden were to be seen not only wood pigeons, but squirrels. The very greenness was restful. Indeed, some people seemed to value the Heath because, they said, it was so good for their children's eyes."

There was an interesting discussion upon the various beautiful features of the Heath and the best means of preserving them.

Mr. Alfred East, A.R.A., spoke with enthusiasm of his, and all artists', delight in the Heath. He reminded his hearers also of "the value of its associations in its wild state with so very many great men. It was loved by the poet Keats, who wrote that exquisite 'Ode to the Nightingale' here. It was the chosen home of the leader of the renaissance of landscape art—John Constable. These associations with Hampstead Heath in its natural

state were of immense value, and should never be broken."

Mr. Walter Field, A.R.W.S., spoke of a member of the Hampstead Heath Protection Society who had died recently, Mr. Gordon Chisholm, who had sketched on the Heath sixty years ago with the great artist William Müller. Mr. Chisholm was over eighty when his warm love of the Heath induced him to join the newly-formed society.

The urgent question of repairing the bald places on the Heath without introducing any discordant note, of assisting, not altering, Nature, was discussed by the meeting generally. The chairman promised that the committee would note the points agreed upon and do their best to fulfil the object required.

Readers know from past comments in THE GARDEN that the society has our cordial support, and it is unnecessary to again express at length our thoughts concerning its important work.

"IN A SMALL WAY."

NOTES FROM AN OBLONG GARDEN. III.

February 14.

I HAVE a lovely plan for next month, and the beginning of it must be arranged for at once. In the front of my oblong—the portion which lies between the house and the road, and which is partly occupied by the stable, against which a tiny greenhouse is built as a lean-to—there is a patch of grass, which forms an illegitimate short cut to both greenhouse, cold frame, and stable, and which is now a bare eyesore, the weakness of human nature taking the servants invariably and myself occasionally across it as a thoroughfare. It is a fairly sheltered spot and gets the afternoon sun, and I propose to make of it something quite out of the way for an oblong. Perhaps I am ridiculously ambitious, but I do not see why Mr. Barr's plan of growing Nymphæas in sunk tubs should not be carried out in a small way here. There is only room for two tubs, but better two than none. An oil barrel is ordered, and when it comes will be cut in two round the middle, and with the bottom taken out this will make two miniature ponds. Two holes will be dug, the staves sunk, and the water made to stay *in situ* by puddling with clay, after the direction in Barr's catalogue. The rain-water supply is close by, so that any loss from evaporation can be easily made good every day in hot weather. Round the two sunk tubs, which are really not tubs, but may be called so for convenience sake, I shall make a sublined rockwork border, and plant Lythrum and the Globe Flowers, with their roots well tucked up in the grateful cooeth of stones. This bit of ground is not very dry even as it is, so I fancy they will do. The worst thing about the plan is that climbing ambition has fixed its desires on *Laydekeri rosea*, which costs 15s., is a lovely pink colour, and smells sweetly; while *odorata pumila*, the little white fragrant Water Lily from America, is much more likely to succeed in such humble surroundings, and only costs 2s. 6d. or so. The yellow Nymphæas are all much cheaper than the pinks in proportion, and I am inspired to try *Helveola*, a little pale Evening Primrose-coloured plant with pretty bronzy leaves, for my second tub. The planting is simple enough, but good quality heavy loam is indispensable. A layer of well-rotted cow manure is put in first, then loam and a little manure about a foot deep; then the Lily rhizome, tied to a turf or stone, is planted, and the water let in. Mr. Barr recommends the addition of a little broken-up charcoal to keep

everything sweet, and I think that the addition of an inch or so of river gravel on the top of the loam would improve the appearance of the miniature pond still further. Nymphæas are fairly hardy, especially in these parts, but they must be protected from frost, for which purpose I shall have a wooden cover made for each pond, which, with the near neighbourhood of the heated greenhouse, ought to answer, as only the severest frost gets into the cold frame close by. Business is very active in the greenhouse just now, for the oblong expects to be largely supplied from it. As I like a perennial garden

and it is pretty closely planted, the borders being blocked out in lengths of 3 feet or 4 feet, each devoted to one class of planting—there is no room for bedding-out, but there are always gaps to be filled up. I am keen on having the encircling walls, which are of old limestone, delightfully lichened and full of cracks, thick with *Stoncrop*s, *Houseleeks*, and *Dianthus*. I have mixed seeds of all these with stiff soil, and pushed it into all the chinks, and sown Wallflower and the Cheddar Pink in the interstices of the coping; but in case of failure, the second halves of all the packets have been sown in the cold frame, and a box of mixed Saxifrage seedlings in this greenhouse is making second leaf. The interest of raising perennials from seed is not half appreciated. They can be sown almost at any time in a warm greenhouse, and there they are not so slow in germinating as when only sown in a summer frame after the approved fashion. I have *Viola cornuta* just thickening in a pan close to the glass and a big panful of seeds of the hardy *Primulas*, so that the pan is a standing dish in the greenhouse for many months. *Pentstemon* hybrids occupy another pan. One block of the sunny border is devoted to these lovely flowers, which are not thought half enough of by amateur gardeners. Their flowering time is so long, if they have plenty of manure, and they are so useful for cutting; while even if a very severe winter finishes them, two or three potfuls of early autumn cuttings kept in a cold frame will furnish a fresh supply very easily. All flowers with campanulate or tubular blooms, from the spotted Foxglove to the glorious *Gloxinia*, appeal to me very strongly, and my earliest joy among them is in the *Fritillaries*. These are supposed to be rather particular and to do best in shade, but I find they will grow anywhere here. Anything more exquisitely fairy-like than an unexpected white or yellow *Fritillary* dancing on its hair-like stem I defy Oberon himself to show me, and they take up little space, yet they are very seldom seen in gardens. M. L. W.

Bathwick, Bath.

AMERICAN NOTES.

A TEACHING SCHOOL OF PRACTICAL HORTICULTURE.

PRACTICAL beginning of what promises to be a most important movement in horticultural advance is made in the recent action taken by the Committee for the Improvement of the Condition of the Poor in New York city, in acquiring land for a horticultural school. This committee, which was formed in 1896, has as its original members A. S. Hewitt, R. F. Cutting, W. E. Dodge, Mrs. J. S. Lowell, J. H. Schiff, Howard Townsend, Mrs. A. B. Comstock, and Professor I. P. Roberts, of Cornell, but has since been greatly enlarged.

Acting under the advice of Mr. Powell, a farm has been taken at Chappaqua, thirty miles from New York city, and in direct communication with the New York Botanic Garden, which latter institution will co-operate with the new teaching school of practical horticulture. The purpose of the movement is to demonstrate the value of horticultural work in its practical application as a means

of relieving much of the agricultural distress of to-day, and at the same time to train up a race of expert practitioners. The institution will work on lines entirely distinct from what are followed at present by any teaching institution in the country. It will be for practical application of practical methods; in short, commercial horticulture as against investigation of scientific principles, and will, indeed, form a connecting link between the higher education of the agricultural colleges and the bread-and-butter work on the farm.

The 200-acre tract of land, which has been secured through the generosity of one of the members of the committee, is admirably adapted for experimental horticulture. It contains a good proportion of orchard land and a variety of sites adapting it for the several crops which will have to be grown. The institution, while looking toward the improvement of the conditions of the people, is not a charity, but is founded with a view to demonstrate the value of real work, to build up a healthy sentiment in the realisation of the value, dignity, and importance of work for its own sake, and to better the methods of horticultural practice as applied to every-day life.

In this country, with all the wonderful advantages of State agricultural colleges and their experiment farms, we have yet been much behind some European countries in the opportunities of training young gardeners and horticulturists in the actual handicraft of their profession. At last the blank seems likely to be filled.

It is a somewhat interesting antithesis that what is practically the Chiswick of American horticulture sees its light in the same year that the council of the Royal Horticultural Society of England is forced, through the development of urban growth, to abandon the time-honoured and historic gardens of that name in England, which have shed such a lustre on the horticulture of the world.—*American Gardening*.

RECENT PLANT PORTRAITS.

THE last-issued number of the "Dictionnaire Iconographique des Orchidées" contains portraits of the following thirteen Orchids, species and hybrids:

Cattleya Leopoldii var. *purpurea*.—This highly-coloured Orchid, though placed under *C. Leopoldii*, M. Cogniaux, in the text accompanying the figure, questions as to the probability of its being a natural hybrid.

Cattleya Schaudiana.—Known so well to all Orchid growers, that a detailed description is not required.

Cattleya Atlanta var. *splendens*.—This handsome form of *C. Atlanta*, already described, has been raised by M. Peeters between *C. Warscewiczii* crossed with pollen of *C. Leopoldii*. With flowers much larger and colour more brilliant than *C. Atlanta*, it deserves the varietal name *splendens*.

Cattleya Waddelliana.—A very fine hybrid, raised by Messrs. Veitch between *C. Bowringiana* crossed with pollen of *C. Warscewiczii*, which latter it much resembles.

Cattleya Ella.—Another of Messrs. Veitch's fine hybrids between *C. bicolor* and *C. Warscewiczii*. A flower of remarkable size and colour.

Cattleya Goossensiana.—This remarkable hybrid has been raised by M. Peeters from *C. Schilleriana* with pollen of *C. Gaskelliana*. It is dedicated by M. Cogniaux to M. Goossens, the artist who illustrates the "Dictionnaire." It bears a richly-coloured flower with a large handsome lip.

Cypripedium A. de Lairsse.—A grand hybrid of large size and distinct marking, raised by M. Peeters between *C. Curtisii* and *C. Rothschildianum*. In appearance it takes more after the latter.

Cypripedium Mulleri var. *Dr. Climp Doorebos*.—A fine hybrid between *C. Lawrenceanum* and *Rothschildianum*, intermediate in form and colour between the parents.

Lisochilus Horsfallii.—An old plant rarely found now in cultivation, producing tall, many-flowered spikes of delicate rose colour and maroon.

Oncidium Kramerianum.—This is the old and well-known *Butterfly* Orchid, so wonderful in form and rich in colour.

Oncidium rubrum. One of the many small-flowered *Oncidiums* with branched sprays of red-brown blooms with yellow lip.

Stanhope Wardii. - Another introduction of many years ago, bearing quaintly-formed blooms of bright yellow with numerous small spots of red-purple.

Vanda Sandoriana. A good form of this most remarkable *Vanda*, or *Esmeralda*, as it is sometimes called, varying so much from the typical *Vandas*, that with one or two others it is placed in a subsection of the family under the name *Esmeralda*.

THE INDOOR GARDEN.

LACHENALIAS.

IN no way do *Lachenalias* show to better advantage than when grown in circular wire baskets. Their natural habit of growth is a semi-pendent one, which renders them just suitable for suspending in a greenhouse or conservatory. This style of growing these naturally drooping plants is preferable to having them in pots. When once the bulbs are established in the baskets it is not necessary to disturb them for three years.

If 2 inches of the surface soil is pricked off in September and replaced with turfy loam and cow manure in equal parts, this will be sufficient to assist the growth each year, with the addition of weak liquid manure freely given when growth is in full swing. The more the plants are fed within reason the more luxuriant will the foliage be, and for baskets the leaves play an important part in the beauty of the plants, as they serve to hide the wire.

The bulbs of *Lachenalias* increase fast when they are in a healthy state. When re-arranging the bulbs in the baskets it is a good plan to sort them into two sizes for the sake of uniformity when in flower. The best time to shift them is when they start into growth in September or early in October.

The baskets are easily made of galvanised wire (No. 8 size). The size of the basket may vary according to circumstances, such as the number of

bulbs at disposal and the site they are to occupy when in flower. Those 18 inches in diameter and 15 inches deep afford space for a very fine display. Line the basket with common green moss from the woods to prevent the soil falling through between the wires. The bulbs are placed in layers, commencing in the middle at the bottom of the basket, and placing the point of the bulb in such a way that the leaves will grow through the wires and

however, be daily moistened to keep it in a fresh condition. When growth has fairly commenced water must be given freely.

As regards compost, *Lachenalias* are not too particular. Three parts of fibrous loam and one of leaf-mould and cow manure, with a plentiful addition of coarse silver sand to keep the whole porous, form a suitable soil. When the plants have done flowering they should be hung in the full sunlight, gradually withholding water from them as the foliage shows signs of ripening off. When this has wholly taken place the baskets may be hung up in a cool shed, where they can remain without water until the time again comes round for renewing.

As to variety, although *L. Nelsonii* is generally regarded as quite the best, there are other deserving sorts. *L. tricolor* is an excellent variety for baskets, as it is quite easy to grow and blossoms profusely. *L. aurea*, a free-growing yellow-flowered variety; *L. luteola*, having yellow flowers with green and red markings; *L. quadricolor*, scarlet, yellow, and green with a crimson edge, and *L. pendula*, with rich crimson flowers tipped with green, are all worthy of attention. E. M.

RIVIERA NOTES.

AMONG the crowd of early-flowering bulbous Irises, *Iris assyriaca* can hardly be said to take a first place. Its large bulb makes one hope for more vigorous growth than it actually attains to, but its quiet grey-blue flowers are prettily raised above the bold recurving foliage, so that a good group of it is not without considerable merit. There is a curious similarity in the shade of blue between it and the lovely *I. sinensis*, so beautiful and so full of flower just now, but it entirely lacks the grace of form and bright golden markings that distinguish *I. sinensis*. *Iris assyriaca*, however, is much more lasting in individual bloom.

After some weeks of delightful weather it is sad to say that a severe fit of cold and heavy fall of snow visited us this morning; it is too early to say how much damage has been done, but as the snow has melted in the morning's sun there may not be much injury to plants unless it freezes again at night. It will be curious to hear how other places fared on March 8. E. H. WOODALL.

Cimiez, Nice.

NOTES OF THE WEEK.

Early flowers at Kew. The Royal Gardens, Kew, increase in interest as the year ages, and recently on a cold March day Crocuses were scattered in profusion over the Cumberland mound and in the grass near the entrance from the Green. Kew in spring is a garden of flowers, and a thousand *Daffodils* are showing through the grass to continue the flower beauty commenced with the Snowdrops and the Crocuses.

Dwarf Irises. Every spring one is charmed with the various dwarf Irises which gladden one's eyes with their brilliant colours; some, too, are precious for their exquisite scent. But one's pleasure is dimmed by the recognition of the fact that but a very small remnant consent to live more than one year with us, and this note is written in the hope that it may elicit suggestions from those who have been more successful than we can claim to be. Of all the common forms, *I. histrioides* is the only one that seems perfectly contented. *Histrio* may linger a year or two, and so with *Bakeriana*, *Rosenbachiana*, *reticulata* (both forms the less attractive *Kreklagei* being the more persistent), but none seem to be here proof against some foe, be it fungus, climate or some other cause. I know of a garden in Worcestershire where *I. reticulata* increases and multiplies as fast as *Scilla sibirica* or *Chionodoxa*; this is in light soil, in beds on terraces on a steep hillside. Quite

LACHENALIA NELSONII. (HALF NATURAL SIZE.)
(From a drawing by Agnes Cook of flowers sent by Mr. Allan, Garsdon Park Gardens, Norfolk.)

hang downward. Strong bulbs may be planted 3 inches apart. When filled, the baskets are at once hung in a light position in a cool house, where the growth will be stocky. If they are given too much heat the leaves are liable to become drawn, which spoils their appearance, and the flower-spikes are not nearly so strong. The soil being moist, water will not be required for a week. The moss should,

lately I have heard of it near Wimbledon flourishing as vigorously in stiff soil almost resembling clay. What is the secret? Here in Reading we have no soil—20 feet of gravel lies below us, and we must put in whatever soil we deem our plants require. Stagnant moisture we do not fear. Would that those who have succeeded, especially such as have gardens resembling this, reveal wherein the cause of failure lies. One's perplexity is increased by the fact that here and there in some odd corner a single bulb of *I. reticulata* will live and thrive for years.—A. C. B.

A note from Ireland.—May I say how glad I was to see "Notes from Ireland" in to-day's GARDEN. I have sometimes wondered why we so seldom see any Irish gardening news in your paper. In spite of frost and unpleasant weather generally we have had our rooms full of Snowdrops for more than a month. The *Lamrustimus* bushes are a mass of bloom, and the Crocuses have never seemed so bright. About three weeks ago we found ten little Primroses in the Scotch Fir wood near the sea. In the garden to-day I found three beauties, and noticed, too, a dear little Primrose out, also *Czar* and *Neapolitan* Violets, Wallflowers, and Periwinkles. In a neighbour's garden the Mediterranean Heath and yellow *Nemophila* are ready for the hoes, and plenty of *Anemones* and *Polyanthuses*. The winter *Jasmine* still looks bright, but *Pyrus japonica* is nearly over. The buds of the common double Daffodil and the graceful princeps give promise of early flowers, and make us feel that the most beautiful of all the seasons of the year, the spring, is very near.—O. C., *Carrowgarry, Co. Sligo*.

[We think that our correspondent's yellow *Nemophila* must be *Linnanthus Douglasii*.—Eds.]

Botanical work at York.—Messrs. James Backhouse and Son, Ltd., of York, have inaugurated a new department in their nurseries, which may be of great service to botanical lecturers and demonstrators, in providing a supply of material especially for microscopic work. They have issued an extensive priced catalogue, comprising objects in the Myxomycetes, Algae (including diatoms), Characeae, Fungi, Hepaticae, Musci, Pteridophyta (prothallia and vegetative organs), Gymnosperms, and all the more important orders of Angiosperms. The department is under the management of an experienced practical botanist, Dr. Arthur H. Burt, and seems likely to supply a long-felt want. *Nature*.

Iris japonica. This Iris, now in flower, is very much in the way of the *Morcas*, lately figured and alluded to in THE GARDEN. It is in every respect a very beautiful plant, and under greenhouse treatment keeps up a succession of its charming blossoms for about six weeks. The Japanese Iris is seen at its best when grown in good sized masses or clumps, as in the Cactus house at Kew, where it is just now very attractive. The flowers, which are borne on a branching spike, are of a beautiful pale mauve colour, blotched with yellow, and are about 3 inches across. A kind of fringed crest forms a very conspicuous feature of the flower, and owing to this it is sometimes met with in gardens as *Iris fimbriata*, while another name for it is *I. chinensis*. Its cultural requirements are not at all exacting, yet many fail to flower it in a satisfactory manner. The principal consideration is good drainage, a soil that will stand for years without renewing, as it flowers best when pot-bound, and full exposure to the sun in order that the rhizomes may be ripened. T.

Croci at Kew. Few flower gardeners seem to know the great wealth of Croci, not the Dutch forms merely, but species and their varieties. It is interesting to see a small collection of the most beautiful near together, as we noticed a few days ago at Kew, where small beds are filled with distinct species of beautiful colour. We made a note of the following: *C. biflorus* var. *minor*, the old Cloth of Gold Crocus (*C. susianus*), *C. Korolkowii*, the ordinary *C. vernus*, *C. Tommasianus*, a charming flower, purplish rose, and large; *C. etruscus*, pale like; the handsome *C. Imperati*, *C. Siberii*; *C. chrysanthus* var. *insculptus*, a Crocus of remarkable colour, deep butter yellow, and *C. reticulatus*.

Phlox maculata, the spotted-stalked *Phlox*, introduced into this country originally from North America in the year 1740, is in danger of becoming lost. I find no evidence of its presence in this country beyond a few examples in the herbaceous borders at Kew, and it speaks volumes for those ably conducted gardens that so many forgotten treasures are retained there. It may be argued that *Phlox deussata* has been so improved of late years, that there is no need of other species. Few will dispute the fact, however, that the large blooms of the improved varieties of the latter have assumed a very indefinite shape, or mop-like contour. There is room for improvement by giving breadth to the trusses in preference to the conical shape, and the habit of *Phlox maculata* with its flat-topped trusses would seem to be a good model to work from, and an equally desirable parent to work upon in the effort, whilst increasing size of bloom, to retain the original form of truss, with a better display of each bloom upon tall *Phloxes*.—W. EARLEY.

Agathæa cœlestis.—When the Marguerite became a popular flower, this *Agathæa* also advanced in favour, and, under the name of the Blue Marguerite, it made its way into many gardens where as *Agathæa cœlestis* its merits had been previously ignored. If stopped during its earlier stages, it forms a neat bushy specimen that will flower more or less continuously throughout the year. The Daisy-like blossoms are a pleasing shade of blue, and being borne on fairly long wiry stalks, their value in a cut state is thereby enhanced. If cuttings are struck in the spring and the young plants shifted on as required, they will by the end of the season form good specimens in pots 6 inches to 8 inches in diameter, and will in a warm greenhouse flower throughout the latter part of the autumn, during the winter, and often well on into the new year. For winter blooming the plants should, after mid-summer, be stood outside in a sunny spot in order to ensure good sturdy growth and an ample supply of flower-buds. Should the plants show a tendency to bloom before they are required to do so, the flowers may be picked off. This *Agathæa* was introduced from the Cape of Good Hope in 1753, but its popularity is quite of recent date. H. P.

The Mountain Avens. *Dryas octopetala*, of Scotch origin, and therefore hardy and

endurable, is a member of the extensive family of Rose-worts, which should be better known and more generally grown. The young leaves it forms annually somewhat resemble small Oak leaves, the delicate coloration of which is so highly appreciated, from amongst which rise its eight-petalled white flowers, somewhat resembling *Anemones*. The plant is very suitable for a front rank border plant and rockeries, but, as regards the latter, should be planted in clefts beneath which are goodly depths of soil. It thrives best in peat soil, and is propagated from seeds, cuttings, and by division—the cuttings to be made in summer and covered with a hand-glass. There is a dwarfier form, named *Dryas octopetala minor*, which is more compact in growth. I may add both are evergreens. I observed lately at Kew Gardens, *Dryas Drummondii* (yellow-flowered), all other species being white-flowered) doing well in the open border. Though a North American species, it is classed amongst half-hardy evergreens. It is deserving attention, though absent in trade catalogues. *Dryas* of this class make pretty pot plants.—W. EARLEY.

Achillea tomentosa, or Downy Milfoil of British origin, has become prominent of late years in connection with carpet bedding, but has not, in accordance with its real merits, yet taken its proper position as a herbaceous border plant, a front row plant in particular, for which it is so well adapted. It is a more pleasing permanent subject than many that are habitually grown—a permanent evergreen with an effective downy appearance, which displays prominently its bright yellow flowers. It is suitable both for growing in tufts and as an edging.—W. E.

SHELTERS.

PART of the garden at Oakwood, Wisley, before some Poplars grew up was much exposed to high winds, and for some plants we wanted shade, so the question of shelter from wind and sun had to be considered. We began with sheep hurdles, which answered to a certain extent, but the feet on the ground rotted and they were not high enough. We had higher ones made, but they were very clumsy, so we tried iron cattle hurdles with cut Furze or Heather worked in between the bars. For some purposes these answered well. If Japanese Rose hedges are wanted, young plants grow fast against this shelter, and by the time the Furze has rotted the Roses have made a good fence. We next tried scrim from the Willesden Paper Company stretched over the iron hurdles; but this after a time looked shabby and the scrim rotted. We at last arrived at a shelter which we think practically answers every purpose, and is easily portable. We have a great many of this sort in use and have thoroughly proved them. I send on a photograph. The iron hurdle is five-barred; it stands 3 feet 6 inches out of the ground and is 6 feet wide; 3-foot common laths are tied by tarred string to the hurdles, two sets one above the other overlapping about 9 inches; this gives stability and a height of shelter of 5 feet 3 inches, which is enough for most purposes. One cross piece is put above the hurdle to stiffen the laths. The laths do not touch each other, so air passes between them. The whole shelter, iron, laths, and twine, is well painted over with black varnish, which we get from Hill and Smith, of 118, Queen Victoria Street. We make up the shelters for our own use, but if there is any likelihood of a demand for them, I could send a pattern to Messrs. Hill and Smith, who supply the iron hurdles, and ask if they could supply the shelters complete from their country works. All I should ask is that they should be called "The Oakwood Shelters." I believe wooden shelters are used in Holland, but I have never seen them and do not know how they are made. GEORGE F. WILSON.

Heathbank, Weybridge Heath.

PLANT SHELTER AT OAKWOOD, WISLEY.

THE FRUIT GARDEN.

GROWING APPLES FROM CUTTINGS.

MUCH has been written in favour of growing Apple trees from cuttings instead of the orthodox or generally followed plan of grafting or budding them upon various stocks. I have repeatedly made experiments with many varieties to test the suitability of the plan or otherwise. I must say I cannot think how any person can advocate the principle of raising trees from cuttings. My difficulty has been to induce them to strike at all. I have inserted cuttings in August, September, and October, even in the spring, and with but indifferent results. The only varieties I could ever induce to root at all are Manks Collin and King of the Pippins. The former is the better adapted to this mode of increase. Even this does not grow freely enough to make a tree and give a fair return. There

desirable practice would be a great gain in more than one way, for exhibitors would find that the appearance of their fruit was actually improved, while all persons of taste while visiting the show would far rather see Melons and Grapes shown with a natural garnishing of their own leaves than bedded in oddly-irrelevant nests of pink paper.

CANKER IN FRUIT TREES AND ITS TREATMENT.

M. PIERRE PASSY in the current number of the *Paris Revue Horticole* writes as follows about the above-named subject: "Canker is a serious disease of the branches and shoots of fruit trees; Pears and, above all, Apples are attacked by it, but all varieties are not equally subject to this malady. There are some which are a deal almost entirely to resist its attacks, while others, on the contrary, such as the *Reinette du Canada*, are specially liable to suffer from them. It is also an undoubted fact that the conditions of locality have a great influence on the evolution of this disease. It is, for example, in confined and damp situations, in narrow valleys, and in low-lying and damp soils that the disorder

that the cause of death was not a Saprophyte which had established itself in tissues which were already dead. We have this year confirmed these experiments by starting the development of well-defined canker on a variety of Pear tree relatively by no means subject to it. The canker was distinguished not only by its general aspects, but by the production of the fruit-ifying organs of the fungus. We had chosen for this purpose a Pear of the variety named *Bonne d'Ézée*, which, although growing very near the varieties *Duchesse* and *Beurré d'Amanlis*, kinds which are very subject to the attacks of the parasite (as they showed numerous cankers characterised by the two sorts of fruit-bearing organs of the fungi *Conidies* and *Peritheces*), yet *Bonne d'Ézée* was absolutely free from it, which is a proof how little liable it is to this malady. On May 20 we made on a branch of the previous year a small longitudinal incision, into which we introduced by means of a perfectly clean instrument some spores of the conidian form taken from a canker borne by a *Duchesse* Pear. In order to avoid too intense an evaporation, which might easily have taken place at this time, and thus have offered an obstacle to the germination of the spores, and to avoid also the introduction of other germs, the wound was immediately covered up with some Pear tree leaves spread over the incision and kept in their places by two ligatures of raffia. Eight days after the inoculation you could already see on both sides of the incision the spreading of the mortification of the tissues, indicating clearly to a practised eye the nascent canker. Six weeks after the mortification had spread to about six centimetres in length, and already at regular distances you could see the formation of the little button-holes by which the masses of fructiferous stroma escape. In the month of August canker had attained ten centimetres in length, many groups of fructifications having separated themselves from the bark. The branch, entirely circumscribed by necrosis, was visibly perishing, and the leaves borne on the young lateral shoots were beginning to wither and fall. There is no doubt that death was near, and that the branch would certainly not have shot forth in the ensuing spring. This artificial inoculation of canker into a variety not liable to it shows clearly what is the provoking agent, and at the same time the rapidity with which the malady can extend when the fungus is well implanted into the living tissues as was here the case. It also tends to confirm the opinion that *Nectria ditissima* is a true parasite capable of rapidly bringing about by itself the death of living tissues and of causing the special necrosis so well known by cultivators of trees. It follows quite naturally from the above-mentioned details that one should seek in the first instance to radically destroy existing cankers. The most effectual way to do so is to burn the affected branches so as to destroy all the spores, and thus diminish the chances of their dissemination. If one cannot destroy the branches attacked, the cankers must be severally cut out, removing every particle affected by the parasite, and even removing also a portion of the sound wood. The portions removed must then be burnt and the wound healed with a powerful antiseptic. For this purpose might be used a concentrated form of the Bordeaux broth, or the following preparation: Sulphate of iron, 30 to 40 kilos; sulphuric acid, 1 kilo, to 100 litres of hot water. Pour the acid on the sulphate, and then add the water very slowly and with precaution. Apply the mixture as soon as the dissolution of the sulphate of iron has taken place. Then protect the wounds from fresh infection by covering them with some appropriate coating, such as grafting wax, Norway tar, or clean earth worked into a clay with Bordeaux broth; also anti-cryptogamic dustings of all the branches will destroy any spores which may be on them or may be brought to them, and will act as a preventive. Finally, the facility of infection being granted, one should avoid with the greatest care the making of wounds with instruments which have been previously used to cut off branches affected with the fungus. This would be to expose one's trees to a direct inoculation of the malady. All instruments, therefore, should be most carefully cleaned before using.

A GROUP OF OCTOBER FRUIT GROWN IN YORKSHIRE.

appears to be no vigour in such trees; they remain much too close to the surface, although they fruit freely enough. Certainly I shall not be tempted any more to take up time and space in raising trees by this method when I can follow the orthodox system of grafting or budding them on such stocks as the Crab, free, or the English Paradise. E. M.

OCTOBER FRUITS AT SKELTON CASTLE, YORKSHIRE.

It is pleasant to see a picture of a group of fruit so well grown by a good gardener in the north of Yorkshire, and to see it so simply and effectively grouped by an amateur photographer who is an enthusiast for fruit and flower subjects. The basket contains Tomatoes and the good early-cooking Apple *Duchesse of Oldenburg*. The rest of the group comprises the excellent Pear *Louise Bonne of Jersey*, Melon *Hero of Lockinge*, Peach *Bellegarde*, and Grapes *Black Alicante*, *Muscate of Alexandria* and *Barbarossa*. The fruit bears as good evidence of Mr. Batty's successful culture as the grouping does of the photographer's taste.

We cannot help thinking that if some such groupings of fruit, with the beautifying adjunct of related foliage of fine type, were adopted in putting up exhibits of mixed fruit at shows, that such a

is most prevalent. It has also been asserted that it was altogether the result of locality, and that it was inherent in certain varieties. These are, in my opinion, mistaken conclusions. Canker is the result of the development of a parasitic fungus, a fact of which there is no longer any doubt. But often affections which are fairly analogous in form are confounded with those whose cause is very different. Thus many assert that canker is caused by the piercings of insects such as the lamigerous plant-louse, thus completely confounding the affection caused by the insect with that of the fungus. If it is true that after many years the wounds caused by the insect show a certain analogy to those caused by the fungus, and that sometimes this latter fixes itself in the wounds caused by the insect and so aggravates them, it is none the less true that at the outset there is between these two attacks no connection and no resemblance, and one can hardly conceive the attribution to one and the same cause of affections which are so distinct and so different one from the other when they are examined with some care. These confusions can only be the result of inaccurate observation. Many mycologists have for a long time affirmed that the cause of the canker was a fungus, and the experiences of Herr Goeth in Germany have shown that *Nectria ditissima* (Tal.) was a true parasite, causing the death of the organs it invaded, and

Then conditions of locality having, as we have stated above, an undeniable influence on the development of this disease, which is easily explained when the conditions necessary to the germination of the spores and the development of the mycelium are known, one should strive to open out the locality to fresh air and to make the soil as wholesome as possible, so as to render the conditions as little favourable as may be to the spreading of the disorder." W. E. G.

[We have to thank Mr. Gambleton for the trouble he has taken in making the translation of this most lucid and useful article. Eps.]

A LETTER FROM ROME.

THE WINTER ASPECT OF THE PINCIO.

It is interesting to note the effect of winter on trees, more or less foreign, in warmer

seed-pods of an *Acacia*, still green, at a little distance arouse illusive hopes of spring. Planes dangle their prickly balls, and are too idle to scatter their golden silk without a shaking. Even the Limes are unwilling to part with their winged seeds, and almost delude the bees with false hopes of nectar. Leaves fade through sheer weariness, but there is little storm or stress to shake the branches free from the burden of the past summer.

The Ginkgo, or Maiden-hair tree (*Salisburia adiantifolia*), is an exception. A short avenue of sturdy, straight-stemmed specimens of this little-known tree is growing, in full vigour, on the Pincio. They might easily be passed by at this season; but an observant eye cannot fail to notice the short spurs not spines thick set upon the slender branches, which distinguish the Ginkgo from any other tree form.

for flower-beds displayed in so many of them, it is delightful to look with a critical eye at the groups of Palms and evergreen and flowering shrubs, and to find how much may be accomplished by permanent planting. Doubtless the genial climate of the south makes what we call "sub-tropical" gardening both possible and easy. For example, the fine Musas, which were in great perfection but a few weeks ago, have simply had their broad leaves trimmed down to the base, the stumps being fully exposed and needing no sort of protection, and the young leaves being almost ready even now to burst the sheath. Canas, too, are cut off at the ground-line and the dead leaves and stems laid over the clumps. But "natural" planting, which is in vogue here, is in direct contrast to the formal style of the old Italian garden, with its close-clipped walls of Bay and

FERULA COMMUNIS IN SEED ON THE COAST OF SICILY. (From a photograph by Signor Crupi.)

climates than our own. With us, it is true, the dead, crisp leaves may cling to the sheltered side of the Beech or Hornbeam hedge, but the rocking branches of Oak, or Elm, or Ash in our wind-swept isles toss off every leaf and leave us a gracious legacy of bare, interlacing boughs. Acorns fall and seldom leave their cups behind; the Ash and Sycamore drop their "keys"; even the Laburnum holds fast but few of its pods when "stormy winds do blow"; only the Alder sets up its pert little catkins and laughs defiance at the blast. But in Italy, trees, like tired children too long kept awake, seem to fall asleep half-dressed. Loest trees hang out their great black beans amongst shrivelled leaves. The brown panicles of *Paulownia* wait to be pushed off by swelling buds. The beaded

Even so it would have been hard to recognise them had there not been now some weeks ago—a carpet of yellowed, wedge-shaped leaves spread beneath the trees, waiting for the garden barrow; and not leaves only, but an abundant harvest of Plum-like fruits, each containing one large kernel. Most of us know the fine tree at Kew, and it would be interesting to learn whether it ever fruits in our climate. I shall watch with pleasure the budding in the spring and for the flowers to follow.

The arrangement and planting of the Pincio has been done with infinite care, and calls for unstinted praise. When we consider the great difficulty of keeping a public garden—or, for that matter, any garden—year in, year out, at a high level of beauty, and the inordinate rage

Hex and fantastic forms of bird and beast carved out of the living green of Box or Yew. So rare even now is "natural" gardening, that it must have required courage to be its pioneer in a land where formerly "no tree or shrub dared to grow in its own natural fashion" without the intervention of the *topiarius*, or head-gardener, to shear it into shape.

Under such a shorn archway and canopy of Hex, indeed, we pass along by the *Passaggiata*, through the iron gate into the Pincio Gardens. There we bid farewell to *Messer Topiarius*. Trees and shrubs are no longer clipped or tortured. Clumps of Indian Fig (*Opuntia*) bask under the warm shelter of the wall, spreading their huge spiny joints to the sun, well set with unripe fruit. Groups of *Yuccas*, now past their

best flowering, still show many spikes in all stages, which only wait for spring to open, and wait in safety. It has been noticed more than once of late that Yuccas in English gardens are showing unseasonable flower-spikes. No doubt this is due to an exceptionally hot summer; but may it not be probable that in congenial climates they have no set time for blooming, being influenced, like bulbs of Eucharis or Pancratium, rather by the age of the offsets than by the season? Further on, Laurustinus in a sheen of metallic blue berries is an old friend in a new dress. At home the berries ripen—sometimes—but never with such lustre as this. By-and-by we come to some lovely Pepper trees (*Schinus molle*) with their graceful drooping branches and pink berries. This is a tree we must perforce do without. As far as I am aware, it succeeds neither in the sheltered gardens of Trecco Abbey nor on the favoured west coast of Scotland. Soon we turn into the garden proper, with its green turf, its shady trees, its groups of Palms, its flowering shrubs, and its climbers.

For the distinctive feature of the Pincio is to be found in the many happy unions between tree and climber, and an hour spent in noting down some of the combinations tried—some successfully, some less so—by Signor Cav. Palice, the skilful and enthusiastic Director-General of Public Gardens in Rome, is by no means time wasted. At the present moment the Winter Jasmine, in full flower, is charming, festooning here and there a deciduous tree with its yellow stars, or scrambling down the face of an Ivy-clad wall. This is a shrub, to use an antiquated phrase, that no garden should be without, and though we may be forgiven if we prefer variety where there is such wealth of beauty to choose from, yet it is surely true that this fine old winter-flowering plant is too much neglected. It is wonderfully lovely when it is given free license to drape as it will a bare and, perhaps, unsightly tree trunk, or to fall over, rather than to climb up, some crumbling wall.

A combination not so likely to succeed, perhaps, with us, but very good and effective, is an Acacia, leafless meanwhile, into which a Smilax has run rampant, showing off its stiff heart-shaped leaves and coral berries to great advantage. To note a few more. A Magnolia screens with its broad foliage the *Maurandya* winding up its stem. An *Araucaria*, at its last gasp, poor thing, is granted a beautiful screen for its woes in a strong Dundee Rambler or some such Rose. Passion Flowers twine about the bare stems of some of the conifers. Virginian Creeper saucily flings, in autumn, her crimsoned trails over the august boughs of Cedar of Lebanon. Scarcely a tree, in fact, but has its clinging companion. It is a whim of the *maestro*, and we thank him and enjoy it.

All these, however, are but experiments by the way. Roses climbing Roses of every sort—clamber into the trees; Banksian, Noisette, Cluster Roses, with evergreen foliage now and promise of flowers to come. And when the month of Roses is here, Queen Rose will hold her court on the Pincio.

On the crest of the hill, on the further side, looking away to the Borghese Villa, but within the precincts of the Pincio Gardens, a colony of majestic Italian Pines rear their noble columns. How many centuries they have stood there, keeping sentinel over the ages, it is hard to tell, but these ancient trees are solemn in their stately grandeur. For the Pincian Hill is historic ground. But here, too, the Roses have their way and wreath their long shoots about the rugged stems. There is a time to refrain from planting. Is not this one of such?

Roses here are scarcely seenly. One spot on all the hill might well be dedicated to shame and remorse for the crimes of human kind. But the crowd revels in Roses. It recks little whether Valerius dreamed, as he paced his beautiful alleys under the shade of such Pines as these, of the cruel fate preparing for him by greed of wanton covetousness; or of the stern decrees of justice which required the forfeit of the guilty life on the very site of the sacrifice.

"Wait till the Roses bloom," say the Romans; "then the Pincio will be in its glory." The sombre shadows fade—one is recalled to the happier Present and the life of every day. The carriages circle about the gay enclosure; the scarlet cassocks of the German seminarists gleam athwart the green vistas, and the band strikes up the cheerful strain of the march in "Carmen."

Rome.

OUR GARDEN PLANTS AT HOME.

THE COMMON FERULA.

FERULA COMMUNIS is one of the most striking plants of the umbelliferous family. It is a native of the shores of the Mediterranean from Italy to North Africa, extending even to the Canary Islands. At La Mortola the plant is perfectly at home, attaining an immense size in favourable situations without any culture.

Early in February the roots begin to push up their leaves and soon form a mass of elegant bright green foliage. The stem reaches a height of 8 feet to 12 feet, and is much branched from the base to the top and clothed at the joints with smaller bract-like leaves supported by a long sheath; only the umbels at the top of the branches bear fruits.

T. HANBURY.

La Mortola, Ventimiglia, Feb. 22.

[We learn from Mr. Daniel Hanbury's "Phar-

FERULA COMMUNIS.

macographia," a book of vast research and exhaustive record of the history of drugs, that a plant of this family, *F. Sumbul*, produces *sumbul root*, used in medicine and perfumery; that *asafoetida* is a product of another, or rather of two others, of the same genus growing in the mountains of Beluchistan; the drug, which is in the form of a resin, being obtained by scraping or otherwise wounding the upper portion of the root after it has been laid bare for the purpose. Galbanum is another product of the *Ferulas*, and the ancient drug *ammoniacum* was obtained from *F. tingitana*, one of the Giant Fennels that adorn the rocky wastes in many parts of Northern Africa and some of the islands of the Grecian Archipelago. Eds.]

FORMS OF ANEMONE CORONARIA AND A. HORTENSIS.

THE bright-coloured Anemones of the south of Europe, which extend in a wild state from Spain to Palestine, are usually classified under the two species which Linnaeus established, *coronaria* and *hortensis*. Each of these, however, runs into numerous forms, and I cannot help thinking that some of the garden varieties owe their origin to hybridisation. There is a very elaborate paper upon the forms that grow wild in the neighbourhood of Grasse by the Abbé Pons, in volume 36 of the Bulletin of the Botanical Society of France, which should be studied by those who are critically interested in the subject. Here I will merely enumerate and briefly characterise the forms which have been treated by recent authors as distinct species, taking as my guide the new "Flora of France," by Rouy and Foucaud, still in course of publication, of which the first volume, which contains the Ranunculaceae, was issued in 1893.

Anemone coronaria is distinguished by its thin leaves with numerous narrow divisions, distinctly lacinated involucre, and 6-8 imbricated obovate-obtuse flower divisions (sepals), which are nearly or quite an inch broad in the ordinary garden form. Of this, Rouy and Foucaud admit nine varieties as follows:

1. *A. cyanea*, *Risso*; *A. coronarioides*, *Hairy*; *A. coronaria*, *Moggridge* (Cont. Fl. Ment., t. 51). — Flowers lilac, without any distinct star at the base, divisions 6-8, much imbricated. Anthers not apiculate.

2. *A. albiflora*, *Rouy and Foucaud*; *A. alba*, *Goaty and Pons*. — Flowers pure white throughout. Anthers not apiculate.

3. *A. rosea*, *Hairy*. Flowers rose-violet or paler, without a distinct basal star. Anthers not apiculate.

4. *A. fernensis*, *Shuttleworth*. This differs from the last by its more globular flower, with acute bright rose-red divisions, without a basal star of white.

5. *A. coccinea*, *Jard*. Flowers large, bright vermilion-red, without any distinct white basal spot. Anthers not apiculate. A common garden form, usually considered to be typical *coronaria*.

6. *A. Monansii*, *Hairy*. — Divisions of the leaves broader than in the foregoing; flowers violet, more or less deep in hue; divisions narrowed to a short acute point, no white basal star. Anthers not apiculate.

7. *A. grassensis*, *Goaty and Pons*. Flowers middle-sized, bright red, with a distinct white basal star, divisions oblong, acute. Anthers apiculate.

8. *A. ventricosa*, *Hairy*. Flowers large, white or yellowish-white, with a transverse red central band round the middle inside. Anthers apiculate. This is the form that is figured as

coronaria in the *Botanical Magazine*, tab. 841, and in Reichenbach's "Icones," tab. 4648.

2. *A. Rissonia*, *Jordl.*—Flowers large, mottled red and white, divisions pointed, basal star distinct. Anthers apiculate.

In *A. hortensis* the leaves are firmer in texture, with 3–5 wedge-shaped lobes, cut down slightly or deeply from the apex, an involucre often of three entire lanceolate leaves, and a flower with 8–18 spreading linear divisions about a quarter of an inch broad and pubescent on the outside. Of this, Rouy and Foucade admit six varieties as follows, which I am extending to seven:—

1. *A. stellata*, *Lam.*—Flowers 1–1½ inches diameter with 12 linear obtuse pale red divisions, without any white basal spot. This is the common wild form of the species figured by Moggridge (*Cont. Fl. Mentone*, t. 2), Sibthorpe and Smith ("Flora Græca," t. 515), and Reichenbach (*Icones Fl. Europ.*, t. 4649).

2. *A. grandiflora*, *Pons.*—Flowers large (reaching 3 inches to 4 inches diameter), violet or rose coloured, divisions broader, more acute, basal star none.

3. *A. fulgens*, *J. Gay.*—Flowers larger than in the type, bright red, without any basal star; divisions obtuse, ¼ inch to ½ inch broad.

4. *A. pavonina*, *Lam.*—Like the last, but divisions of the flower very numerous, linear. Both this and the last frequent in cultivation.

5. *A. variata*, *Jordl.*—Flowers 1½ inches to 3 inches diameter, rose-red or bright red, rarely whitish or lilac, with a distinct white basal spot; divisions 8–10, sub-acute.

6. *A. lepida*, *Jordl.*—Flowers 1½ inches to 2 inches diameter, violet outside, purple inside; divisions 8–10, oblong lanceolate, acute, whitish basal star distinct.

7. *A. Regina*, *Risso.*—Flowers 1½ inches to 1 inches diameter, divisions oblanceolate, acute, bright red, ¼ inch to ½ inch broad, basal star distinct, whitish or straw-coloured, figured by Moggridge (*Cont. Fl. Ment.*, t. 1) and called in the third division of his book *A. hortensis* var. *ocellata*. This, like *fulgens*, runs into a *pavonina* form, as shown in the top flower in Moggridge's figure.

A plant which Herr Max Leichtlin sent me some time ago from Beyrout must surely be a hybrid. It has a coronaria flower, bright red, with six obovate, obtuse, much imbricated divisions, a deeply lacinated involucre, and a thick leaf with three deeply lacinated wedge-shaped lobes. J. G. BAKER.

Kew, Feb. 27.

GARDENING OF THE WEEK.

KITCHEN GARDEN.

ASPARAGUS.

THE wintry weather experienced during February will have prevented ground work being attended to; but it frequently happens that a mild spring follows a hard or changeable winter, and there should be no delay in doing up the Asparagus quarters ready for the spring cutting. For some years I have advised growing this plant on the flat and giving more room than is often allowed. I am aware the latter advice is much easier given than carried out, as every inch of space must be made the most of. When the beds are hoed or pointed over with the fork they may have a dressing of soil and fertiliser, or, what is better, burnt refuse and food given as a top dressing. I am not in favour of manuring beds in the autumn; it is far better to feed during growth, and with the plants on the flat, and given ample space, it is a good plan to place well-decayed manure between the rows now; this soon gets pulverised by the weather, and acts as a mulch if

the summer should be dry. Of course, in feeding, a great deal depends upon the nature of the soil; if this be wet or clayey, the operation is better deferred for a time. New beds will need less food than old ones, few manures being superior to liquid from stables.

RHUBARB.

Where this is needed in quantities for forcing it is well to plant a certain number of roots every year. Few roots need better treatment, as though the plant will grow for many years in the same spot, nevertheless, by ample food and good culture a better return is secured from a limited space. The ground should be deeply dug, or, better still, trenched, and a liberal supply of manure worked in as the digging proceeds, and if possible a change of quarters is beneficial. An old root will cut up into a good number, each portion of root detached having a bud or crown, and the work is best done as early in March as possible, planting firmly at 4 feet to 5 feet apart. If manure can be spared, it is a good plan to cover the surface, as afterwards this acts as a mulch and encourages new surface roots. No stalks should be taken the first year if the young stock is needed for forcing, and only a little for those intended as stock plants, as it is better to draw from the older plants. An equally good way to secure plants or new stock is by sowing seed; this sown in good land will give a fair return in two years, and by sowing in a frame and planting out the seedlings in June, time is saved. Thin sowing is needed in any case, also early thinning of seedlings.

AUTUMN-SOWN ONIONS.

If not yet planted out in their finishing quarters, these should be taken in hand at an early opportunity, as the plants are making new roots and will need careful lifting. The plants should be planted on land richly manured and deeply dug, the food being placed well under the roots. In light soils it is advisable to tread the soil before planting. A liberal space should be given between the plants and between the rows, as it allows of working more freely and feeding later on. Onions delight in ample supplies of liquid manure and other food when in active growth. In planting, each bulb should have the roots carefully spread out, and each made firm as the work proceeds. G. WYTHES.

Syon House Gardens, Brentford.

FRUIT GARDEN.

GRAPES.

VINES in 12-inch pots should not be allowed to bear more than six or eight bunches, and if at the time of thinning more were left than the vines are capable of bearing, it will be well to reduce the number without further delay. Afford manure water frequently up to the time of approaching ripeness; it is better to give it weak and often than strong applications at long intervals, and changing the manure has a beneficial effect, at one time giving that from the drainage of stable manure, and at another a concentrated form that is known to be suitable to vines. If the pots in which the vines are growing are plunged in hothed material, maintain a regular moderate warmth of about 75° by frequently adding a little fresh manure and leaves. Suitable atmospheric conditions are the same as recommended last week for permanent early vines. They must be frequently examined as to the state of moisture of the soil; a lack of attention in this respect would ruin them altogether. They should be examined every day when the sun is bright, while in time of dull weather they will not be safe longer than two days together. When the soil is found to be only slightly moist, upon no account leave it till quite dry, but afford a liberal supply of water.

Vine eyes put in this season, as soon as the young growths from them are about 3 inches long and the roots begin to work round in the pots, are then in a suitable condition to be potted into 5-inch pots. Place an inch of crocks at the bottom, and use loam enriched with a sprinkling of bone-meal, potting firmly; afterwards plunge where there is bottom-heat in a light position in a forcing house.

"Cut-backs" is the name given to young vines that are cut down after the first season's growth, canes from which are grown and ripened the second season earlier than is easier done from eyes the first season; in their third season they are the most adapted for very early forcing. When the young shoots have grown to the length of 3 inches or 4 inches—which they have now done if they were placed in slight warmth a short time ago—if several shoots are developed on each, disbud to one, the strongest. This is the time to pot them; shake away all soil from the roots without injury and repot them, working the soil among the roots, using the same kind as was used for the eyes, and giving them a similar position. After potting give them a watering, but give it sparingly until new roots have taken hold of the soil. Put a stick to each before they are in danger of being broken off, and guard against overcrowding.

Plant one-year-old vines in recently made borders, laying the roots out straight in a hole previously made 4 inches deep, and as wide as the spread of the roots. Cover them with fine soil, tread firmly, and afford water to settle the soil. Maintain a sweet atmosphere, and temperatures ranging from 55° at night to 65° in the day, with a rise of 10° to 15° from sun-heat. It is advisable to plant the vines 4 feet or 5 feet apart.

Where it is intended to plant out vines in the month of May raised from eyes put in this year, push along with the work of preparing new borders in the manner described in a former calendar.

THE GRAPE ROOM.

As the season advances use less fire-heat, only employing it slightly when the outside atmosphere is damp, and doing without when it is dry. Examine the water in the bottles, and add some to those in which it is likely to sink below the base of the vine shoots. Do not omit to look over the grapes frequently for the purpose of cutting out all berries that have begun to decay. This season Gros Colman and Lady Downe's so far have kept very well, and the first-named has been of unusually good flavour. G. NORMAN.

The Gardens, Hatfield House, Herts.

INDOOR GARDEN.

EUCHARIS.

A FERTILE cause of *Eucharis* failing is the frequent potting which some growers deem to be necessary. My experience is that the best plants are those which are not often potted, and I would not advise potting any that appear to be doing well, for with healthy leafage and rational management flowers are sure to come, and there are few other plants which are so amenable to the will of the grower as are these. At the same time, to prevent actual starvation it becomes necessary to repot now and then, and I have found the best results and the least check to growth from potting in February. If the plants are from any cause unhealthy, I prefer to remove all the soil from the roots by immersing the ball in a tub of water for several hours, but healthy stock may be potted on intact, taking care not to over-pot. A fair amount of drainage is necessary, and over this some rough lumps of fibrous loam. The potting mixture may be two-thirds loam and the remainder equal proportions of peat and sand. Keep the bulbs low in the pot.

The lower the better, provided some soil is used between them and the drainage—it being a mistake to allow a big body of soil below them or to have their crowns above or near to the surface. After potting, half plunge the pots in a gentle hothed and keep the foliage fresh by frequent syringing. Of course, the plants are most easily grown in a house to themselves and kept to a stove temperature, but very good results may be had with a little increased trouble where there are succession vineries and a house the temperature of which does not fall below 50° in which to winter the plants.

CARE OF FORCED PLANTS.

Among the many plants grown for forcing there are sure to be some that will repay the trouble of a little care when flowering is over if room can still be found for them under glass. The latest batches scarcely suffer at all from the gentle forcing they get, providing they can be kept growing without a

check. Among the mollis Azaleas are some of extra good colour, and these should certainly be preserved. They may even be grown to give good crops of flowers two years in succession if not hard forced, though as a rule it will be better to give the plants a year's rest. The same may be said of the Staphyleas. Deutzias should, after flowering, have all the weak spray cut away and many of the old stems cut out entirely, with a view to encouraging young growths of a robust nature from the base. Solomon's Seal, now becoming popular as a forced plant, will form fresh buds after the roughest kind of treatment in the way of being hard cut, though next year's growth from such buds will only be medium sized, and without flowers they will give just the right sort of greenery for use in small vases of cut flowers.

Narcissi in variety, with the sole exception of the old Paper-white and the improved forms of it, Daffodils, and the latest forced Tulips, if assisted to ripen off gradually under protection, will be useful for planting out and embellishing the rougher parts of the garden or the spring flower borders, and even Lily of the Valley can be kept for planting with advantage where the out-door stock consists of the small variety so often seen, as the Berlin crowns when established give a much better class of flower.

J. C. TALLACK.

Shipley Hall Gardens, Derby.

THE EVENING PRIMROSE.

(*ENOTHERA LAMARCKIANA*.)

It is not often that one sees in gardens so favourable an example of the advantage of having one good thing at a time as is shown in the accompanying illustration. This fine *Enothera* is one of the best of the rather tall plants for such bold use in half-wild places where there is shade or half-shade.

It is a biennial, but as it sheds its seed freely, when once established in a suitable place there is no danger of its being lost. It is an improved form of *Enothera biennis*, a plant that is rather handsome when one sees it growing wild, but is far inferior to the garden kind. The careful gardener must look out for reversion to the type, which often occur. After a little practice one gets to know the rogue seedlings, when half-grown, by a certain suspicious greenness. The first open bloom, much smaller and rather deeper in colour than *En. Lamarckiana*, of course shows up the rogue at once, but by that time other things are growing tall and a plant may easily be overlooked, and then the garden is in danger of being overrun with seedlings of the more unworthy plant.

How beautiful a thing is this tall Evening Primrose in the late summer evenings, when its flowers, that are closed and drooping in the hottest sunshine, are wide open and giving off their delicate scent, or, better still, in the calm daylight of the early summer mornings before the sun is up.

If it is cut and put in water when the blossoms are fully expanded, they remain wide open, and will last in beauty for several days.

Index and Editorial Notices will be found amongst the advertisements.

NARCISSI FOR POT CULTURE AND EARLY FORCING.

THE present is, perhaps, of all seasons in the year the one when good and showy flowers with long stems are valued most, as the lengthy season of the Chrysanthemum is once more at an end, and the greenhouse and conservatory are in consequence rendered more or less destitute of useful flowers. Not that it is possible with anything else adequately to fill the gap thus caused, though it is possible for the interval to be considerably shortened. The only flowers that can thus quickly be brought into prominence, with due preparation, of course, are Narcissi. Not only are most of these showy to a degree, they are also rendered the more serviceable by being endowed with long and by no means frail stems. This, whether intended for the decoration of the greenhouse in pots or grown for use in a cut state, renders them more attractive and adds to their general decorative value. They remind us, too, of the coming spring. Forced flowers we have had to a greater or less extent for years; it has, however, remained for modern gardeners to show

moist enough for Daffodils." The soil being "moist enough" is often misleading, because at this time of year when gloom and moisture pervade the very air we breathe, it is not easy for soil to become dry, hence errors occur quite unintentionally. In the case of the Daffodil there is a great profusion of roots to be catered for, and moisture must ever play a leading part in building up good foliage and flowers.

Heat also is frequently misapplied. Only a year ago in calling on a large grower I found he had not only introduced his Daffodils to one of his hottest houses, he had also placed them on a strong bottom-heat. Unfortunately, they had been so treated for three weeks when I saw them, and their ruin was complete. The grower had been advised so to do as a preliminary to successful forcing. It required but little argument to convince of the error in such case. Needless to say, the root fibres were quite ruined and not an atom of top growth was made. Potting should be done early in autumn, so that a full complement of roots may be produced long before they are taken to the greenhouse. When taken thither the place should be cool and freely

A WALK OF EVENING PRIMROSE (*ENOTHERA LAMARCKIANA*).

what real value there is in this now large family, and how well they may be grown with care and discretion. Perhaps not the least important feature in the early forcing of Narcissi is the abundance of foliage obtained, which is not possible in all hard-forced flowers. Indeed, forcing injures many plants by blanching the blossoms and causing the leaves and stems to come pale. In the Daffodil family there is none of this injury by hard forcing and the foliage is as dark and handsome as the flowers generally are good. Naturally not a little depends on how the work is done, and of course in this as in other matters there have been failures as well as successes.

A very common error in forcing the Narcissus is that insufficient water is given at the root, whereas with good drainage it may be said that it is scarcely possible to err on the side of over-watering. Upon more than one occasion my opinion has been asked by those growing these flowers under glass for the first time, and invariably I find the soil too dry. In giving this opinion I have been met with the remark: "Oh, but that soil is moist enough for anything"; and my reply has been, "No, it is not

ventilated, closed by degrees and warmth administered in like manner. Assuming the bulbs may be introduced early in December and potted early, they will at that time bear a temperature of 45° to 50°, depending to some extent on external conditions. I have found it a good plan in dealing with these flowers to avoid much warmth till the flower-scape is free of the neck of the bulb. Great heat or sudden variations of temperature prior to this stage frequently results in failure, and even if a flower is obtained, in all probability it is a distorted one. When the flower-scape is free of the neck of the bulb, a little more heat may be applied, but there is no need where good flowers are required ever to exceed 55° at night.

I have already spoken of moisture at the root. Of equal import is atmospheric moisture, and on no account must this be neglected. Bottom-heat should never be employed; indeed I do not know a single kind that is assisted by it, while nearly all strongly resent it. A point of importance in forcing these flowers is that too frequently the value of the more plentiful kinds is overlooked, and it is worthy of note that what are considered the commonest

kinds are among the most serviceable for early forcing. Thus the better kinds may be reserved for more natural flowering later on. Even with our hosts of good Daffodils, none can surpass the following for the very earliest forcing. Ard Righ, or Irish King, and Obyvallaris or the Tenby Daffodil both coming very close together, and the well-known double Daffodil following about three days later. A grand kind when well done is Golden Spur, but this, as also does Horsfieldii, requires a little more time and is best regarded as semi-early. A very useful and graceful kind is Princeps; this comes away in advance of the last-named, and with gentle forcing produces splendid stems and foliage and blossoms of the most serviceable kind. Though a very short list, it will be found ample for very early forcing, avoiding more expensive sorts.

Hampton Hill.

E. JENKINS.

AN ARTIST'S NOTE-BOOK.

LILIA JONGHIANA.

IT was a fortunate day for Orchid growers when this beautiful Brazilian plant was lately re-discovered and imported in quantity; and, coming into bloom as it does between the autumnal-flowering *L. pumila* and the spring-flowering *L. majalis*, which it more closely resembles, it is of considerable value for early spring decoration, and

Aconite. For a description of it we refer our readers to Mr. Gambleton's note on p. 183, March 10.

IRIS STENOPHYLLA.

It is not often that such a distinct species is introduced as this new Iris, which was shown at the last February meeting of the Royal Horticultural Society by Messrs. Wallace, of Colchester, when it received a first-class certificate. No species can be compared with it except in size, and this is *L. alata*, but it is even more refined. The new-comer is without the rough outline of *L. alata*, nor does it possess the very broad blade to the fall of the latter. But in one feature it does suggest *L. alata*, and this is the way in which the claw from the lower side embraces the style, only that in *L. stenophylla* it is more uniform and definite, quite overlapping the entire upper surface of the style by the extended wings that meet on the central surface. The azure-blue, purple-shaded flowers are very beautiful, while the richly-coloured blade of the fall might be that of a handsome

view, do not quite agree with all that has been published on this subject. All the more am I thankful for the admirable words of Mr. G. D. Leslie (page 146), and am confident that many of your readers feel with me: "A garden is fenced in from wild Nature and for man's private use and enjoyment." It is so true! Wild Nature can never be our garden proper. I am leaving out of consideration those larger gardens or parks in the arrangement of which landscape effects can and must be studied, but allude only to those plots of ground which we know as a cottage or a villa garden. In these there is no room for wild Nature, however much we may admire her, though perhaps our love of her, of this inexhaustible source of ever-changing combinations of living form and colour, so fertile also of edifying meditation, should be felt to be the main impulse for the creation of our gardens. As we stand enraptured viewing a beautiful natural scene, our eye delights in the masterly contrasts of foliage and flower, of undulating turf, and perhaps winding waters and picturesque rocks. The beautiful picture attracts us to the spot, but and what a lesson to vain humanity!—the

LILIA JONGHIANA.

(Drawn by H. G. Moon from flowers sent by Mr. J. T. Bennett-Poe.)

also is likely to prove useful for hybridising. The first record of its flowering in Europe was in the year 1872, and it was figured in the *Botanical Magazine* in 1873, but for many years it has been little known but as a name. The blooms, of considerable size, between 5 inches and 6 inches across, are of a soft rose-purple tint, and produced solitary or in pairs, as in the case of *L. pumila*. The brilliant orange-yellow disc of the lip and the exterior blotch of yellow on the side lobes give it a distinct appearance. As yet it has not flowered in sufficient quantity to determine the extent of its variability.

J. T. BENNETT-POE.

ERANTHIS CILICICA.

SEVERAL notes have appeared in THE GARDEN lately about this interesting and rare Winter

Iris reticulata. The species is destined to become one of the most notable of the early bulbous group.

E. H. JENKINS.

[This beautiful new species is a native of Asia Minor, and is closely allied to *L. persica*, being similar in growth and very distinct in colour; the flower is nearly 4 inches across, and borne on a stem between 3 inches and 4 inches high, the standards of a soft blue shade, the falls intense blue bordered with white. EHS.]

FALSE IDEALS.

WITH the keenest interest have I followed the honest words written in your, or may I say our, GARDEN against supposed false ideals. I am a gardener, and perhaps for that reason looking at the matter from a different point of

our private use and enjoyment." Primarily the garden is for our private use; it is not for all; it is ours; every plant it harbours is our own; we know them all individually, for we rear them from year to year; we enjoy our garden, and no more noble purpose could it serve.

The arrangement of it cannot be but of secondary importance. We cannot reproduce the spontaneous vegetation of wild Nature, as we cannot replace the hand which created it. We may well preserve a wild scenery in larger parks; there we may even be able to create circumstances by judicious selection and planting, which, if left to develop naturally, may ultimately lose the mark of our handiwork; but we cannot plant wild Nature. Such an attempt would bear the stamp of absurdity on

its face, so let us not deceive ourselves with petty imitations.

The arrangement of the garden should be governed by good taste, of course, but not dominated by reasons of appearance. The often too narrow confines of the garden may, for the sake of the well-being of some of our dearest plants, dictate such grouping as is not exactly in accordance with our own ideas of harmony. If there is a tree too large or too thick for the healthy development of more dainty plants below or beside it, sacrifice it or parts of it. If the hedge interferes with any plants, let it be trimmed, and, lest it present an untidy appearance, be trimmed evenly all round. The arrangement is imperatively a matter of convenience also. The walks must be well made and well kept, for at all times must we be able to approach our friends. Tidiness is necessary for obvious reasons; so let the garden bear the marks of it. It gives a feeling of comfort to the one who feels responsible for the treasure the garden harbours. Let the lawn then be shorn and its edges be cut accordingly. Much the prettiest gardens are those in which the loving hand of their owners is evident. If close comparison is the object of the observing flower-lover, there cannot be any objections to formal rows of plants placed side by side.

Look through your own GARDEN. Your beds are of formal shape, scrupulously trimmed; even the giant Beech tree, which I could have admired so much in its broad spreading fulness, is mutilated in order to give prominence to the tiny Crocuses which it shelters. It is not your intention to curtail the tree, but branches were cut away to show us those pretty flowers, and your purpose justifies your measures. Thus let everyone's heart choose how and what to plant in his own garden. It will then be a natural garden; we shall then see no more imitation birds cut out of the Box bushes, nor shall we see the unhappy rock gardens any more, for which the rocks alone seem to dictate the name; nor the shrubbery robbed of its flowers by untimely trimming and the fruit tree mutilated by reckless pruning. We shall then see individuality and no more mere copying in the garden.

A RARE WINTER
ACONITE (ERANTHIS
CILICICA).

(Drawn at Kew by
H. G. Moon.)

To spread the knowledge of the requirements of the plants, to teach us their culture, to make us know the treasures which distant climes and countries produce for us, to show us the pretty flower which at our very door we are so apt to overlook, to teach us to see the beauty of Nature—that is a laudable purpose, and everyone will thank THE GARDEN workers for their patient endeavours in this direction.

Where the garden is looked at solely as a necessary environment for a dwelling-house, it is no more a garden proper, but a decoration to the main object; it is primarily then a matter of appearance and convenience. The purpose is a good one and worthy of the most hearty support of all, though different from the object of a true garden. For this decorative garden the gardener is generally called in to set out a few suitable trees and shrubs, and, perhaps, flowers. Here he should show his individuality; here he should show his art of combining to the best possible advantage the two purposes which a garden can serve. The success of his work is, of course, dependent on many circumstances; not the least is the goodwill or the purse of his employer. But remember, you may not always blame the gardener if you do not like his work; he is often, too often, the instrument only of his master—none more than he suffers if he has to work without his heart—and he should be spared the reproach if a commonplace result is the outcome of an unhappy compromise between his ideas of a good garden and the orders of his master. THEO. ECKARDT.

I PERCEIVE from the perusal of Mr. Leslie's letter on the above subject (page 146) that in my remarks upon the clipping of shrubs I was not sufficiently careful to observe the axiom, "Write not so that you may be understood, but so that you cannot be misunderstood." In deprecating the fashioning of disconnected evergreen shrubs into rounded mounds of greenery, a practice annually observed in innumerable English gardens, I had no intention of condemning the clipped evergreen hedge. There is no *raison d'être* for spherical or quaintly modelled shrubs scattered about the grounds, whereas in almost every garden dividing lines are necessary, and these may often be more fittingly formed out of living growth than with stone or bricks. A well-kept Yew, Holly, or Box hedge creates an admirable boundary, and, as Mr. Leslie says, no more effective background can be conceived than the sombre green of Yew for enhancing the charms of the "well-arranged herbaceous border," while such a hedge emblazoned in the summertime with the vivid scarlet flower-trails of the Flame Nasturtium is in itself an object of unsurpassable splendour.

As far as I am aware, the class that advocates the absolute and unrestrained rule of Nature in every part of the garden exists only in the imagination of the votaries of the artificial, who, in order to disparage the opponents of their style, set up an altogether false and exaggerated standard as being the aim of those who agree with Kingsley that "the further you get from Nature the nearer you get to bad taste," in order that they may demolish it by contemptuously describing it as "arrogant intility." As to lawns, I think most of us agree with Dudley

THE NEW IRIS
STENOPHYLLA.

(From a drawing by
H. G. Moon.)

Warner, that "one cultivates a lawn with great satisfaction, for there is nothing more beautiful than grass or turf." One of the primary objects of lawns and grass walks is to afford a cool and velvety surface for the foot during the heat of summer, and it therefore follows that the better a lawn is kept the more nearly it attains this desirable end. In the same manner garden seats, pergolas, summer-houses, bridges and fountains have one and all their uses, and if simply designed and not overlaid with trivial and needless excrescences, a practice too apparent in the so-called "rustic-work" that disfigures so many gardens, add to rather than detract from the beauty of their surroundings; while in respect to the value of water in the garden, one is inclined to echo Bernard Pallissy's words: "It is impossible to have a spot proper for a garden unless there be some fountain or stream passing through it."

I trust I have demonstrated that I am fully in accord with Mr. Leslie and his "wise little girl" in appreciating that "happy medium" which both he and I alike deem desirable, and I imagine that few, if any, lovers of Nature and of the garden hold a contrary view.

In my two notes on "False Ideals" I have taken exception only to the undue dwarfing and doubling of our garden flowers, to geometrical carpet bedding (while allowing that bedding and other tender plants are often of the greatest use in the garden), and to the clipping into unnatural shapes of isolated shrubs, for I am not at one with those who accept the dictum laid down in a recent work that "Yew trees trimmed close gain their full beauty." In conclusion, I think I may safely say that nothing I have written suggests the inference that I object to a clipped hedge in its proper place, to smooth lawns, pergolas, or to a fountain of artistic design, and if there be those who disapprove of these things I have yet to meet them. S. W. FITZHERBERT.

Iris reticulata major. We have received a boxful of flowers of this beautiful Iris from Messrs. Kelway and Son, Langport, Somerset. This is a much larger form than the type, but of the same warm colour and strong Violet fragrance.

ORCHIDS.

ORCHIDS AT OAKWOOD.

WYLLAM, a country village on the banks of the river Tyne, will ever be famous to growers of Orchids through that ardent hybridist, Mr. Norman C. Cookson. A bleak day in February, with the country covered with ice and snow, was not the best time to inspect a collection of Orchids; but there are always Orchids in flower in every establishment, and in Mr. Cookson's garden I found a wealth of beautiful kinds. The collection is almost entirely formed from seedlings raised in the Orchid houses, but a certain proportion is composed of fine varieties of the more popular species. In one of the Cattleya houses the eye is at once arrested by two of the finest varieties of *Odontoglossum crispum*, viz., *Cooksonii* and *Mundayanum*. The first-named, I believe, was obtained by Mr. Cookson from a small batch of imported plants. It was a small plant when first exhibited before the floral committee in the old Kensington garden of the Royal Horticultural Society, where it obtained a first-class certificate. By careful management and the most skilful culture, this one small plant has now developed into fourteen fine plants. It is well figured in the "Orchid Album," vol. iii., plate 118. The white sepals and petals are irregularly and heavily blotched with brownish crimson, the white and yellow crested lip being similarly blotched. The variety *Mundayanum* is also a distinct and striking Orchid. This is well figured in the second series of the "Reichenbachia," vol. i., plate 5. It is brownish crimson, with crimson-purple blotches, the latter showing unusually distinct on the back of the petals. I wondered at seeing these cool-house Orchids in the Cattleya house, but Mr. William Murray, the head-gardener, informed me that the flowers develop more freely in the higher temperature. I thought what splendid varieties might be obtained if the two forms could be cross-fertilised. Doubtless this has been considered in all its bearings, for handsome cross-bred *Odontoglossums* have been raised and flowered at Oakwood.

A handsome hybrid *Laelio-Cattleya* was in flower; this is a cross between *Laelia purpurata* and *Cattleya Dowiana*. It is some twenty-two years since the late Mr. Dominix proudly showed me a plant from this cross in flower under the name of *Laelia Dominicana*. He had sown the seed some sixteen years previously; that would give thirty-eight years or more since the cross-fertilisation. A similar cross was exhibited two or three years ago under the name of *Apollonia*, and received an award of merit from the Orchid committee. Later a still better form was exhibited by Messrs. Veitch under the name of *L. C. Jangleysensis*. This received a first-class certificate from the Orchid committee. It would be better to return to the early nomenclature. It is a handsome garden hybrid and delightfully fragrant. The white forms of *Laelia anceps* make a fine show in the Cattleya house. The variety *Schroederiana* is one of the best; the pure white flowers are marked with crimson lines in the throat. *L. anceps Percivaliana* is also distinct and pretty. I cannot hear that anything has been done in crossing these white *Laelias*; personally I own to continual failures with them.

Since writing the above paragraph Mr. John Seden has successfully crossed *Laelia anceps* and *Laelia purpurata*. The plant was exhibited by Messrs. Veitch on February 27 as *L. Edissa*; it is described on p. 172 of THE GARDEN.

The numbers of hybrid *Cypripediums* raised at Oakwood are legion, and still they come. *C. Sanderiano-Curtisii*, the most recent Oakwood acquisition, was well figured in THE GARDEN (p. 74), and *C. Sanderiano-superbians* is equally handsome. These *C. Sanderianum* hybrids are well described by Mr. Chapman in the same number. One of the most useful and handsome of the Oakwood *Cypripediums* is *C. Calypso* (Oakwood variety); it is a cross between *C. Spicerianum* and a good form of *C. Boxallii* the variety *atratum*, I think. The

vigour of the plants show that *C. Boxallii* is the seed parent. This is a matter of considerable importance, for unless the seed-bearer is vigorous, it is unlikely that the seedlings will either be vigorous or long-lived. A rather handsome hybrid was in flower, unnamed, between *C. Stonei* and *C. Argus*. The dorsal sepal has the distinguishing traits of *C. Stonei*, while the elongated lateral sepals have the spotting of *C. Argus*; the spots and blotches not so thickly placed as in the famous *C. Stonei platytenuum*, but reminding one of that variety.

One of the glories of the Oakwood collection of hybrid and bi-generic hybrid Orchids are the *Phaio-Calanthes*. As long ago as 1867 *Phaio-Calanthe irrorata* flowered in Messrs. Veitch's nursery at Chelsea by crossing *Phaius grandifolius* with *Calanthe vestita* var. *Turnerii*. Mr. Seden made a similar cross some time later.

There is now in flower some very beautiful *Phaio-Calanthes* at Oakwood. The variety *P. grandis* is a chaste and lovely thing; the sepals and petals are creamy white, with a soft rose-tinted lip. Some of the varieties are much darker than others, and it would be a mere matter of taste whether the light or dark forms were preferred. One very pretty variety had sepals and petals of a dark rose colour with a rosy red lip. These are crosses from *Phaius grandifolius* and Oakwood Ruby *Calanthe*. *Phaius Sanderianus* crossed *Calanthe* William Murray has produced a fine batch of seedlings; all are distinct and handsome. The rosy buff sepals and petals, with the spreading white lips of some of these, are great acquisitions to the large family of home-raised Orchids.

Most Orchid fanciers remember the sensation caused by the advent of *Phaius Cooksonii*, a cross between *P. Wallichii* and *P. tuberosus*, combining the characteristic features of both parents. The sepals and petals are nearest to *P. Wallichii*, with the handsome lip of *P. tuberosus*. *P. Normanii* was raised later from *P. Sanderianus* crossed with *P. tuberosus*. The progeny are again intermediate; some of the varieties are very beautiful, and even surpass *P. Cooksonii*. The interest in any collection of Orchids in the future must largely centre upon the seedling plants and in the distinct forms which are found in importations. I intended to have said something about the numerous fine *Calanthes* raised at Oakwood, but this must be left for a future occasion. J. DOUGLAS.

THE ROSE GARDEN.

ARRANGING ROSES IN THE FLOWER GARDEN.

SHOULD there be a rosarium in a large establishment, or is it preferable to group the Roses among the other occupants of the garden? The answer seems in favour of the latter, for one rarely hears of a really good rosarium. In years gone by, except during a short period, a Rose garden was apt to appear rather a dull spot, but this need not be so at the present day if preference is given to the glorious Monthly Roses, among which I class the Tea-scented as well as the Bengal or Chinese.

When a rosarium is formed it is a common practice to have a centre bed of standard Roses. I cannot say I admire this arrangement even if the trees grow freely, which, unfortunately, they sometimes do not. I would rather see a glorious mass of climbing Roses in the centre running over a bower or some old tree stumps. What a beautiful centre-piece for a rosery would be the fine specimen of Bennett's Seedling, so well depicted in the "Century Book of Gardening"! Certainly such kinds would not blossom for any great length of time, but they might be surrounded by dwarf Tea Roses that would go on flowering after the climbing Rose had ceased. As regards standards and half-standards, these seem to do more to beautify the rosery if allowed to develop into fine drooping heads, such as the William Allen Richard-son depicted in the work alluded to. It seemed

to me that a few such specimens as these were the one thing wanted to complete the harmony of the lovely Rose garden Mr. Tate has formed at Downside. Many of the fine climbing Tea and Noisette Roses should be more frequently employed as standards and half-standards; they make such graceful heads, much more so than the stiff, erect-growing Hybrid Perpetuals. Many Roses that are never thought of as standards, such as *Gloire des Rosomanes*, *Armosa*, the common Monthly, *Stanwell Perpetual*, *Longworth Rambler*, *Paul's Single White*, *Gyrus au Toplitz*, *Macrantha*, *Penzance Briars*, *Ayrshire* and *Evergreen* Roses, and many others, would make delightful drooping heads of bloom entirely free from any artificial appearance. If I were forming a rosarium I should not be anxious to dispose of the plants so that they could all be seen at a glance. To come upon a group unawares would give greater pleasure.

A delightful feature of the Rose garden at Kew is the grassy dell with Roses on each side. This dell, I am told, was once a gravel pit, and some hundreds of cartloads of loam were employed to form the huge mounds, which are faced with rugged stumps of trees. The *Crimson Rambler* grows with wonderful vigour in such soil, and many of the delightful early Roses, for instance, *Rosa lutea*, *R. hispida*, the *Carmine Pillar* Rose, Scotch Roses, also some beautiful new hybrids in the Japanese and *Boursault* tribes, here find a congenial home.

Now that we have our collections enriched with the pretty creeping Rose, *R. Wichuriana*, and its many lovely hybrids, unthought-of effects can be produced by their aid, for they will run about and root like Ivy and cover the earth with their charming flowers and refreshing glossy foliage. Neither in a rosarium nor, indeed, anywhere else does a bed of mixed Roses show to any great advantage. If I could only grow three plants of a kind, I should plant those three in a group by themselves. There is such a diversity and individuality among Roses, that they need to be so disposed to obtain the benefit of their full beauty. Many lovely Roses which are usually bunched up to a stake to form a pillar would appear far more natural if allowed to grow without this artificial support. In our hedgerows we see this wild, yet elegant, style to perfection, and what can be more lovely than the graceful fountain-like branches of the Dog Rose laden with their delicately fragrant blossoms in June?

I once saw a very pretty little rosery formed upon the side of a slope, surrounded by huge *Rhododendrons*. Of course the soil had to be imported for the rosery. It can be easily imagined what a fine background of foliage the *Rhododendrons* afforded, and they also acted as a splendid shelter from keen winds.

I think when a rosarium is formed upon an extensive scale many single specimens of evergreen and deciduous shrubs could be advantageously introduced without producing any incongruous effect. Of flowering shrubs, the most suitable would be well-developed specimens of such things as *Forsythia suspensa*, *Philadelphus speciosus*, *Spirea arifolia*, *Pyrus Malus*, *Scheideckerii*, &c., or graceful evergreens of the type of *Juniperus chinensis*, *Osmanthus ilicifolius*, *Thunbergia borealis*, *Phillyrea decora*, *Laurestinus*, *Yucca recurva*, *Pinus excelsa*, broad-leaved *Hollies*, *Weeping Spruce*, and others. Golden evergreens and bright-coloured flowering shrubs would be best avoided. I should plant weeping Roses rather extensively to relieve the flatness, and would endeavour to find space for one or two of the exquisite weeping deciduous trees, such as *Young's Weeping Birch*, *Weeping Cherry*, *Weeping Almond*, *Weeping Poplar*, *Sophora japonica pendula*, and others. Beautiful as they are, I think it is a mistake to crowd the rosarium with the strong-growing single Roses which have come so much to the front lately. The sunny side of a shrub border seems to be the most fitting place for such Roses unless space can be afforded to grow them as single specimens upon or in the vicinity of the lawn. The *Penzance Briars* are delightful as single specimens, and the same may be said of *Hebe's Lip*, *Macrantha*, *Janet's Pride*, *Andersonii*, &c. But what is to become of

the Moss Roses, the Damask, Mme. Hardy and Painted Lady, Maiden's Blush and Celestial, the Hybrid Chinese, Blairii No. 2, Coupe d'Hebe, and Charles Lawson, the York and Lancaster, and a host of other old favourites? I would suggest that they be grown as individual specimens. If no other place is available, put them in the herbaceous border, which surely is the most fitting place for them. Those who are not exhibitors, but who wish their gardens to appear beautiful, will doubtless accept these disjointed thoughts in the spirit in which they are written. A. R.

SEASONABLE ROSE NOTES.

Roses under glass started in December will now be in a forward condition; consequently, weak doses of liquid manure should be given at every other watering. Many growers believe in adding some good artificial fertiliser to the soil when repotting in July. This is an excellent practice, as the roots can utilise the food when required. One is apt to be too generous and afford more than is necessary, with the consequent injury to the small rootlets. A 5-inch pot of a good reliable phosphatic manure is ample to each barrowload of the compost, which consists of two parts of unsifted loam and one part of decayed manure. I refer to this now because if such stimulant were given at the time mentioned it is obvious that at this period weak doses only of liquid manure are required. Failing this addition, a sprinkling of artificial manure now will be necessary.

Watering the plants is work that should be carried out by a most careful workman. When the foliage is fully developed, Roses require plenty of water, but much of this may be given through their leaves, hence the need of a moist atmosphere. The soil should not be allowed to become thoroughly dry, but, on the other hand, it must not be over-watered. Water-tanks or barrels of water should be provided in each Rose house.

Roses planted out under glass are much assisted now by a mulching of cow manure and wood ashes in addition to the sprinkling of bone-meal they receive after pruning. The result is soon manifest in the splendid foliage, and it is surprising how little aphides infest thoroughly healthy foliage. When, however, they are observed, fumigate immediately. The syringe should be freely used on bright days. See that the water is forcibly directed to the under side of the foliage, for this is where the red spider lurks, causing discoloration and the untimely dropping of the leaves. A few pots of button-hole Roses placed in ainery just started will afford many useful flowers. The beautiful Sunrise, Isabella Sprunt, Niphetos, Safrano, Queen Mab, &c., are excellent for this purpose. Should no plants be available, a few might be purchased established in 8-inch pots. Such plants require no repotting. All that is necessary is to examine the crocks and clear them of soil, then remove an inch of the surface soil. Give a sprinkling of some good fertiliser, covering this with an inch of fresh loam and well-rotted manure in equal parts. For button-hole work very moderate pruning is best. Cut out the small twiggy growths from the centre and retain the remainder almost their entire length.

Hybrid Perpetuals, Hybrid Teas, Moss Roses, and the delightful China and Polyantha Roses, such as Mme. Eugene Rosal and Perle d'Or, which have been established one year and kept since November in cold pits, may now be given a temperature of 45 to 50 at night. I find hard pruning the best for such plants. Cut the one-year-old wood back to the second, third, or fourth eye, the topmost eye

looking outward. About twelve weeks will elapse between the pruning and the blossoming. As growths develop and flower-buds form, 60° at night may be given. This has a tendency to lengthen the stem, which is very desirable.

Roses grown for exhibition on the cool system should now be placed upon inverted pots or two bricks and a good watering afforded. Tie the plants out carefully, so that as the foliage develops it may get the full benefit of sunshine and air. A string is placed under the rim of the pot and the growths brought into position by tying raffia to their ends and securing this to the string. The final shaping of the plant is done with sticks as soon as flower-buds are visible. Roses that are now flowering afford wood for cuttings, which should be utilised if increase of stock is desired. I prefer cuttings of two or three eyes, and the healthier the foliage, the better will be the plants obtained. Insert the cuttings round the edge of 3-inch or 4-inch pots in a sandy compost. Of course, an ample supply of crocks must be previously placed in the pots. A 2½-inch pot inverted and

shows its vigour and profusion of big creamy-white spathes, which rise up above the glossy foliage, a wonderfully bold and rich effect against the leafy background. One may judge from the illustration that this Arum is perfectly happy here, and its bold beauty reminds one of the little fields of spathes in the sunny Scilly Isles and the southern parts of the English and Irish coasts. The Arum Lily is a thorough water lover. It inhabits the ditches of South Africa, and is there known as Pig Lily hardly an appropriate description of a plant so luxuriant and beautiful. It would be interesting to know whether the butter-yellow-spathed *C. Pentlandii* and others of this group have been tried in the open garden. Their intense yellow colour is hardly so beautiful as the rich creaminess of the type, but the colour is good, producing a striking picture when the plants are crowned with spathes. The Abbotsbury Gardens are amongst the most interesting in

ARUM LILIES IN ABBOTSBURY GARDENS.

placed on the surface of the cutting pot will keep the foliage from premature decay. All the foliage is retained on the cutting except the bottom leaf. This has the end leaflet removed. When the cuttings are dibbled into the soil, hold the pots for a few seconds in a pail of water, then plunge into bottom-heat of about 65° to 70°, the top-heat not exceeding 55°. I much prefer a frame placed over a hot-water tank in a greenhouse, but many use a manure bed, and, providing the latter is well made and carefully examined to see that the fumes are not injuring the cuttings, it answers very well. On bright days shade the cuttings and sprinkle with water morning and evening. Remove decayed leaves promptly. PHILOMEL.

ARUM LILIES IN ABBOTSBURY GARDENS, DORSET.

Not the least interesting feature of the beautiful Abbotsbury Gardens of Lord and Lady Ilchester is the growth of the Arum Lily (*Calla aethiopica*) in the water there. The illustration

the kingdom, and one day we hope to describe them more fully than at present.

MARKET GARDENS.

THE RATING OF GLASSHOUSES IN MARKET GARDENS UNDER THE AGRICULTURAL RATES ACT, 1896.

THE decision of the House of Lords in the case usually quoted as *Smith v. Richmond* (really the overseers of Worthing v. the district Surveyor of Taxes) is a somewhat serious blow to the market gardening industry.

Nearly a hundred years ago the courts recognised that the rule of law, that whatever was affixed to by a tenant to the land he occupied became the property of his landlord, and could not be removed by himself, wrought a great injustice to those market gardeners and nurserymen who spent large sums in the erection of hothouses and greenhouses for use in their trade. The Court of

Queen's Bench relaxed this rule, which long continued inexorable in the case of an agricultural tenant, and allowed the removal of greenhouses and hothouses as fixtures erected solely for the purpose of trade. This relaxation operated most favourably, and conduced largely to the development of the business or profession of market gardening.

By the Public Health Act of 1875 it was enacted that the occupier of any land used as a market garden or a nursery ground should be assessed to the general district rate of an urban sanitary authority, and to the separate rate made to defray the special expenses incurred by a rural sanitary authority, at one-fourth part of the net annual value of such market garden or nursery ground; or in the case of a rural district where no special assessment was made, such occupier should pay only one-fourth part of the rate in the pound payable in respect of buildings and other property. It then became a somewhat disputed question whether the occupier of a market garden containing greenhouses, &c., should not be rated on the full scale for such erections, and on the one-fourth scale for the part not occupied by buildings. The question came before the law courts in due course, and at last the Court of Appeal decided (in the case of *Purser v. Worthing Local Board*) where a piece of land had been almost entirely covered with greenhouses built on brick foundations, and used for the purpose of growing and forcing fruit and vegetables and flowers for sale, and the local board had rated the occupier upon the full annual value of the buildings instead of as a market garden, that the local board were wrong, and that the land must be rated as a whole as a market garden, for it did not become any the less a market garden because glasshouses were over it. This decision again proved a boon to the market gardening industry, and secured to it the same benefit as was given to agricultural land.

By the Agricultural Rates Act, 1896, the occupier of agricultural land is liable to pay, to any rate to which that Act applies, only one-half the rate in the pound payable in respect of buildings and other hereditaments which are not agricultural land. The expression "agricultural land" is defined in the Act as "any land used as arable, meadow, or pasture ground only, cottage gardens exceeding one quarter of an acre, market gardens, nursery grounds, orchards, or allotments, but does not include land occupied together with a house as a park, gardens other than as aforesaid, pleasure grounds, or any land kept or preserved mainly or exclusively for purposes of sport or recreation, or as a racecourse." Following the interpretation placed in the *Worthing* case on the somewhat analogous provision of the Act of 1875, many judged that even if a market garden were entirely covered with glasshouses it would still be a market garden within the meaning of the Act of 1896, and as such it would still be agricultural land, and entitled to the relief afforded to agricultural land by that statute. But they omitted to notice the full force of the provisions requiring that where buildings and agricultural land had been previously valued in one amount, and the value had been so stated in the valuation list of the parish, separate valuations of the agricultural land and the buildings were to be now made. For the purposes of the Public Health Act of 1875, farm buildings had been assessed separately from the land let therewith, and it had been decided that for the purposes of that Act greenhouses in market gardens were not to be rated separately from the garden, and so, in spite of the provision as to the separation of values, many contended that the market gardens must be rated as a whole, and that the occupier was entitled to an allowance of one-half of the rates to which the Act applied. As was inevitable, the matter came before the courts, but, singularly enough, it was *Worthing* which was again the source of litigation.

Robert Piper, a market gardener and nurseryman at *Worthing*, owned and occupied four acres of land, on which stood fifty-seven greenhouses or glasshouses built on dwarf brick walls in the usual way. Fifty-one of these houses were used for growing Vines, and six were Cucumber houses, within which were dwarf brick walls supporting corrugated iron sheets, upon which earth was

placed and in which earth Cucumbers were planted. These erections covered rather more than two acres, the remaining two acres being merely vine borders, paths, and stake-holes. In their statement the overseers of *Worthing* returned this holding as market garden and nursery ground, and made no separate estimate of the annual value of the buildings. The surveyor of taxes objected, and the assessment committee upheld his contention that the hereditament was not entitled to the relief the statement of the overseers would afford Piper. The overseers appealed to Quarter Sessions against the decision of the assessment committee, and the Sessions allowed the appeal. The court stated a case for the Queen's Bench, which came on before Justices Collins and Ridley, and these judges differing in opinion, the decision of the Sessions was confirmed. The Crown appealed, and the Court of Appeal set aside the order of the Court below and of the Court of Quarter Sessions, the Master of the Rolls and Lord Justice Rigby holding that the statute distinctly and explicitly directed that buildings and agricultural land should be separately valued, and that the antithesis between agricultural land and buildings was the very foundation of the Act. The case went next to the House of Lords, which, after taking time for consideration, upheld the decision of the Court of Appeal, the Lord Chancellor saying, "It is extraordinary that any claim should be made that what is here described is agricultural land. It would be quite as reasonable to claim that any building, however solid and substantial, used for agricultural purposes was agricultural land." He considered the terms "land" and "buildings," as used in the Act, were mutually exclusive of each other.

So, after much prolonged and expensive litigation, the question has at last been settled, and, although the decision of the House of Lords is at least logical, it will to some extent militate against the market gardening interest. To the layman there may seem some conflict between the decisions in *Smith v. Richmond* and *Purser v. Worthing Local Board*, but it must be remembered the cases arose under different statutes. Had the legislature thought fit, when considering the Act of 1896, to direct that all buildings on agricultural land (of course excluding dwelling-houses) used for the purpose of the cultivation of such land should be valued with that land, the agricultural interest and the market gardening interest would have received greater relief, and the principle laid down in the case of *Purser v. the Worthing Local Board* would have been carried to its logical conclusion. N. X. N.

THE FLOWER GARDEN.

THE DOUBLE ROCKET.

TO one like myself who takes a keen interest in the old flowers which have given delight to many generations of flower-lovers, but which are every now and again in danger of being overlooked, it has been a pleasure to see that my short note on the double Rockets has attracted some attention. Feel more than repaid for it by the pleasant letter it has produced from the Rev. Denis Knox, although it begins with a happy bit of badinage caused by a chance remark of mine that my taste was not quite in the direction of such flowers. I imagine that most of us who are fond of flowers and plants in general have to make a choice, which is only made with difficulty and often with sadness, as to which plants we can grow in our gardens. It is often not a question of what we would like to grow, but of what we have an opportunity of growing. I may, however, have been a little unfortunate in the phrase I used, as I certainly had no wish to lead anyone even to think that I did not care for the double Rockets, though that choice which has to be made by all of us has inclined me more towards the cultivation of alpenes. If I have seemed to disparage the Rockets, which I am not prepared to admit, I am quite willing to atone for it, although I feel that I have done these flowers a good turn.

Like Mr. Knox, I feel that flower-colour descriptions form very dangerous questions to touch upon, and it is just possible that the old Rocket variously called crimson and scarlet may be the one of which Mr. Knox speaks as the old double lilac, and a plant of which he has most kindly offered me. If I can again get hold of the old double crimson, I shall hope to have the pleasure of sending it to him for comparison. It is, however, remarkably difficult to lay hold of, and the friend who had it last year has lost his plant, but as he had given one to another friend, I hope to secure it yet. The late Mr. Cameron, of Kirkintilloch, had it last year. This double crimson Rocket was quite well known to some of our older writers, and some in more recent times have also spoken of it, in some cases as the double red. There is no doubt that it exists, though it is possible that the vagaries of colour-nomenclature may have been such that it may prove the same as Mr. Knox's.

The old Scotch White is a dwarfier and more compact plant than that which was figured in *THE GARDEN* the other day. It is not, however, dwarfed to the degree which is properly condemned in the article on "False Ideals." It is still in cultivation, though much scarcer than the other white forms.

It is probable that there are more varieties of the double Rockets in existence than some suppose. Another variety of which I have known for some time, but which I have been unable to hear of in gardens at the present time, is one with flowers which are variously described as striped or variegated with purple and white. I have never heard of anyone who has this Rocket at present, and it seems to have escaped the notice of Mr. Knox in his search for the various double forms. I hope that I may not incur the displeasure of any other flower-loving reader by the remark that I am not favourably impressed with the description of this Rocket. Still, I should like to see it, as it forms one of those links which connect us with those of like tastes who loved their gardens and their flowers in days long gone by, when flowers were scarcer than now, and when times did not afford so many opportunities for gardening.

I have to thank those who have written in *THE GARDEN*, as well as those who have written me privately about the Rockets, for their useful notes.

S. ARNOTT.

Corsehorn, by Dumfries, N.B.

A SPRING-FLOWERING KNIPHOFIA.

K. PRIMULINA is now in great beauty with me in a greenhouse from which the frost has just been kept out during winter. When I first got it I had it in the open ground, but, finding it did not flower till winter, I potted it, and find it is a good pot plant for winter or early spring. The colour is a clear, bright primrose-yellow, and the spikes last a month or more in full beauty. *K. Nelsonii* is also a very good pot plant, though in hot summers like the last it flowers well in the open ground. It varies much from seed, and the dwarfier varieties should be selected for potting. Whether it will survive a hard winter remains to be seen, but, if not, it is certainly worth a place in a frame. *K. caulescens*, which I have lost in hard winters previously, seems to have got through this one successfully, and should flower in May and June. H. J. ELWES.

THE FLAME NASTURTIUM.

(*TROPEOLM SPECIOSUM*.)

By some mischance, *Tropaolium tuberosum*, on the culture of which in South Devon I lately contributed a short note, was indicated as identical with its far more showy sister, *Tropaolium speciosum*. The latter, well-named the Flame Nasturtium, is far less amenable to successful culture in the south-west than is *T. tuberosum*, which, as far as I know, has no equivalent English designation. In the north, especially in Scotland, the Flame Nasturtium grows like a weed and affords sheets of glorious colour, but in the south-west it is the exception to see it displaying its brilliant charms in avarant abandon. Being extremely anxious to establish the plant in the garden, I tried it in a

dozen dissimilar sites, in all but one of which, although carefully attended to, it eventually died; in the remaining one, however, it became thoroughly established, and for the past three years has flaunted the splendour of its vivid bloom-trails during the summer months, followed later on by its less striking, but still decorative, blue seed clusters. The soil in which the plant in question is growing, in a north-east angle of a wall, is shaded by another low wall on its southern side, and never receives direct sunlight throughout the entire year. At a height of 3 feet or 4 feet from the ground-level the shoots grow into a fuller light, and as they ascend further emerge into the full sunshine in which the mantling blossom glows with almost dazzling effulgence. A porous compost, consisting of leaf-mould, loam and road grit, which is kept fairly moist during the summer, apparently suits this specimen to perfection, but as an exactly similar compost was employed in the cases of the failures, it would appear that in this instance it is to site rather than to soil that success is due. This *Tropaeolum* possesses such eminently attractive qualities that it is well worthy of an exhaustive trial, even in districts where its culture is beset with difficulties, since success will amply repay any trouble involved in its establishment. S. W. F.

South Devon.

CHERRY TREES IN BLOSSOM.

No fruit tree seems to show such a bountiful mass of bloom as does the Cherry; and as it is generally the largest of fruiting trees (except, perhaps, some of the great west country Pear trees), the large area on which the mass of bloom is displayed is all the more striking. In company with such a blossoming tree the homeliest of farm-buildings will form a delightful pastoral picture of early summer; while the great wild Cherries of the woodlands, scarcely inferior in size to the largest of our forest trees, deck the wild groves with wide-spread clouds of blossom, while the nightingale is pouring forth his song.

RONDELETIA CORDATA.

In the temperature of a stove, or even in that of an intermediate house, this *Rondeletia* is flowering freely, and a very ornamental subject it is, though very rarely met with. Last spring, however, at an early meeting of the Royal Horticultural Society some good examples were shown, and attracted a considerable amount of attention. It forms a bold-growing shrub clothed with stout leaves, the largest being about 6 inches long and half as much in width. The terminal clusters of flowers remind one to a certain extent of the *Laurustinus*, and, like that well-known shrub, they retain their freshness a considerable time. In the bud state they are deep pink, but the interior of the flower visible after expansion is bluish, with a quantity of yellow hairs in the middle, thus forming a golden centre. Even in the neighbourhood of London it is, after all the fogs we have experienced this winter, in good condition, thus proving it to be of robust constitution. In the "Dictionary of Gardening" two species, *R. cordata* and *R. amena*, are given as natives of Guatemala, but I fail to see any difference between them as generally met with. Though now included in the genus *Rondeletia*, these plants were formerly known as *Rogeria*, a name still retained in gardens with that charming cool house shrub,

R. gratissima, a native of Mexico. This has deep green leaves, and flowers even more nearly resembling the *Laurustinus* than those of *R. cordata*. They are borne during the winter and early spring. *R. speciosa* or *cordata*, with vermilion flowers, is the best known of the genus. H. P.

CORRESPONDENCE.

CRINUM CAPENSE SEEDS.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—Two short notes have lately appeared in the columns of THE GARDEN respecting the seeds or bulbs borne on the umbels of the *Crinum*. Whether these bulbs are, as surmised by Dean Herbert, attached to withered seeds or no, I am unaware, but for all practical purposes the products are

but little if at all affected, as three out of four seeds that I placed on trees on Christmas Day some years back germinated and made good plants. The underside of the crease formed by the junction of a smaller and larger branch is the best site for the location of the seed, as in such a position it is less likely to attract the attention of birds. A covering of muslin or clay has been recommended as a means of preservation from winged marauders, but if attached as above suggested the majority will remain intact. Some advocate slitting the bark and placing the seed in the cut, but seeds merely adhering to the outer surface of the bark germinate with equal freedom. F.

MUTISIA DECTURRENS.

[TO THE EDITOR OF "THE GARDEN."]

SIR, I should like to point out to "A. R. W." that this lovely composite is quite hardy when planted against a wall without protection of any kind above. Your correspondent infers that the overhead shelter is more or less necessary. This is not so. I have grown it in a rather cold northern district, where the plants flowered each year and where overhead protection was unknown. I believe that stonework or brickwork is helpful to the plants, and as a fact I have never tried to grow the plant without such aids. As "A. R. W." points out, there is always difficulty in obtaining supplies, and the suckers are not easily removed with roots attached. I tried many of these before I hit upon the following plan, which, however, requires both care and patience. It is the most successful way I know, and a goodly number were secured with nice roots. A large pocket on the rockery was selected; this was purposely made more shallow by laying bricks in cement below; then followed a thin layer of soil, peat, loam, sand, and charcoal. Now the plant was put in position, being laid on the side of the ball so that the growth should trail over the rockery. The rock pocket was stone on all sides, and when a little fresh soil was added to the plant, a block of sandstone was placed on the top of the ball of soil. The object of this was to attract the sucker-like stolons to the stone, from which they would naturally emerge to the light. When a few points could be discerned pushing through the front, it was considered the time to act, and when the upper stone was lifted off it was found that the suckers had first arisen to the stone, then travelled along and out into daylight. This gave a clear course for treatment, as previously the chief drawback

IN CHERRY-BLOSSOM TIME.

bulbs, which, if planted in the autumn, make good growth the following summer. The white variety of *Crinum Moorei*, known on the Continent as *C. Schmidtii*, also bears these bulbs or seeds in quantity in warm and sheltered situations, thereby affording a far more rapid method of propagation than is admitted of where *bona fide* seeds are sown. S. W. F.

SEEDS OF MISTLETOE.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—On page 132 "Medway" asks for a few Mistletoe berries when ripe for sowing. Some advocate the months of February and March as the best season for propagation, others as late a date as May or June, but there is no reason why berries should not be rubbed on to the bark of such trees as it is wished to furnish with this parasite at any time they may happen to be handy. Though, doubtless, germination is retarded by mid-winter propagation, the fertility of the seeds is apparently

was the necessity of digging among roots and suckers to examine them to see if any were rooted, always to the danger of the plant. This danger was now disposed of at a single blow, and it could be seen whether the suckers were rooted and ready for removal without danger to the parent plant.

These suckers do not root quickly, and I found it hastened matters to just crack the skin with the knife and cover with sand or sand and cocoa-nut fibre refuse. Water was given, and the suckers were then covered up with the stone and left for three months, by which time most were rooted well enough for detaching, which is best done quite early in autumn or in spring. That this is a slow method I am quite willing to admit, but it is the best and the least fraught with danger to the old plant. I have often thought it remarkable that I have never once seen any seeds of this lovely plant offered for sale. Surely such could be had with a little trouble, collected, of course, in the native home of the plant. Always and ever a scarce plant in cultivation, there are many who would like to

possess it could be obtained. Possibly the Kew authorities with their unique correspondence abroad could lend a helping hand by endeavouring to obtain seeds of this plant. E. H. J.

Hampton Hill.

CAN WE IMPROVE OUR ROSE EXHIBITIONS?

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Although during the last two or three seasons great improvements have occurred in the style in which garden Roses are arranged at the exhibitions, there yet remains something to be done before anything like perfection is reached in the displaying of this our favourite flower. To say the least, we are not artistic enough. Monotonous long rows of boxes on monotonous tables have had their day. Let us contrive something better. I do not say we can improve upon the box plan if the fat monstrous blooms are to have it all their own way; but why should they? The general public do not ask for these monstrosities. Frequently in the crush of a Rose show I have heard an exclamation of pleasure pass the lips of visitors who have turned aside to admire groups, naturally arranged with all the delightful buds and foliage retained, even if the individual blossoms were not quite so perfect. This has led me to think that something was wanting different to the orthodox style with which Rose societies regale their patrons. There still remains much to be done before a Rose show is the delightful thing it is possible to make it.

Can any Rose grower deny that the decorative Roses—that is to say, those kinds that bloom freely and almost continually—are not in fashion? Although fashion in flowers is to be deprecated, I cannot shut my eyes to the fact that for once the general public are right. Bold masses of exquisite Teas, Hybrid Teas, and China Roses are much to be preferred to the stiff, although perhaps individually superb, Hybrid Perpetual. But are these decorative Roses displayed to the best advantage at a Rose show? No more handful adequately portrays the beauties of such Roses as Mme. Eugène Rosal, Queen Mab, G. Nabonnand, Camoens, Marquise de Salisbury, Mme. A. Chatenay, and such like beautiful flowers. Therefore, why not invite exhibits of say one hundred sprays of these Roses, cut with long stems and tastefully arranged in vases hidden in mounds of moss? In the matter of grouping, when one visits an early exhibition like that at the Temple Gardens, is it not the tasteful arranging of standard, pillar and bush Roses, which enables the exhibitor to introduce all tribes, that appeals to the majority of the visitors rather than the huge specimen, however magnificent? Therefore, why not try (we who as a nation are probably the largest growers of the Rose, although the Russians run us rather close) and arrange a Rose show upon broader lines, so that those who desire it can form an idea how this beautiful flower may be made to embellish the garden?

In the first place, the exhibition must needs be arranged in a tent; and, speaking of tents, cannot our tent makers invent something to prevent the oven-like atmosphere often too apparent? The Rose is not a flower that will stand excessive atmospheric heat. A cool, showery day sees Roses in greatest perfection; still, as we cannot make the weather, let us try and do something to mitigate the nuisance complained of. Supposing, then, the Crystal Palace authorities provided a tent located upon the grass, with a covered way leading thereto as a provision against storms, and that this tent be put up a day or two in advance, so that all who cared to make an effective group could have plenty of time in which to carry out the work. In arranging a large group everything in the shape of vases, &c., should be placed ready at least the day before the show, excepting, of course, the cut flowers. Prizes should be offered for groups of bush, standard, pillar, and climbing Roses in pots, such groups to be augmented by means of great bunches of cut Roses in vases and other receptacles. Blooms cut with 1½-foot to 2-foot stems would not only be an object lesson (for the novice would learn how to prune the various forms and tribes), but

the show could be rendered artistically beautiful with pillars of Pezance Briars and other delightful single and semi-double Roses. Standards of some of our loveliest Hybrid Teas should be shown, and bushes of many tribes such as the tiny Polyantha, the charming Moss Rose, the delicate tinted Maiden's Blush, the unique coloured Austrian Briar, the robust rugosa, and a selection of the worthiest of the Roses usually seen at Rose shows. Now, objections will be raised, such as the season being too late for pot Roses, or that it is too expensive to move them about. But such a show, to catch the garden Roses at their best, might be held in June; then the difficulty of exhibitors taking about with them vases, epergnes, &c., to exhibit their flowers in, and many similar objections would be sure to arise.

As to pot Roses being over, I maintain that they could (by growing them out of doors) be had in bloom by the end of June. As to the expense of cartage, this would no doubt be considerable for many rosarians, but the enthusiast would surmount difficulties of this kind. As to the early-flowering garden Roses being over, why, then have two, or even three exhibitions, so that all growers and all classes of Roses would have a chance of being represented. Surely an early Rose show is worthy a better fate than the usual Drill Hall company, or rather non-company. There is no better place around London for such an exhibition as I have in my mind than the Botanic Gardens, Regent's Park. Could not arrangements be made with the Royal Botanic Society that would allow the early shows to be held there? Those undulating banks covered with Roses such as I have attempted to describe would be a creditable sight, worthy of a country that claims the Rose as its national flower. As to the expense of the exhibitors carrying about their own vases, &c., this should not be necessary. Let the various societies provide them. They would surely show better taste in their selection than many individuals whom I have seen arranging their beautiful Roses in ugly blacking-bottles. It would be interesting if this subject were ventilated before the time came round for the making of schedules. I am afraid that as at present constituted Rose committees consist of men not exactly averse to garden Roses, but who pin their faith to the show Rose. I am not unmindful of the arguments of our exhibitors that Rose shows are established to encourage good cultivation. Granted that this is so, does not the striving after size rather tend to create apathy against all the lovely gems that are not grouped under the heading of show Roses, and also in careless arrangement of their plants in the garden. One noted grower has asserted that he would not mind growing his Roses alongside a bed of Onions, provided he could obtain good Roses. I opine this would not be the opinion of individuals who care for fragrance in a Rose before even form.

PHILOMEL.

[We print our correspondent's letter as it stands, although we do not entirely endorse some of the statements it expresses. For one thing we think that the function of a well-organised show of any popular flower—and who shall say that the greater of our Rose shows are not well organised?—has not so much for its object the pleasing or tickling of the shallow taste of a general public or any sort of recognition of passing fashion, as an honest and thoughtful intention to demonstrate what in the way of Rose culture is most worthy of effort, and what result of effort is most worthy of commendation.]

We most earnestly desire to approach the large subject of the influence of shows, as one of the most powerful agents in horticultural education, in a spirit of careful thoughtfulness, and above all things to abstain from delivering hasty and ill-considered judgments. We believe that in the shows of some flowers, especially those of Curnations and Chrysanthemums, practices are allowed and even encouraged, and aims are held out as admirable that we hold to be of doubtful soundness. But in the case of Rose shows we have never seen, although perhaps not quite worthily placed in their stiff little stands, other than flowers of individual beauty, and we have never seen prizes awarded to other than blooms whose production should most justly be the pride of their growers.

With regard to our correspondent's suggestion that more should be made of the free-growing Roses, though we think with him that the Teas might be shown in large free bunches in all their beauty of length of branch and freedom of flower, and bud and leaf, yet we believe that even could his desires for better tent-ventilation and more time for arrangement both be provided, it would still be almost impossible to show cut branches of the more rambling of the free Roses, other than Teas and their allies, in anything like good order. For the display of these at shows we shall have to depend as heretofore upon those who will grow them in pots for the purpose. We also fear that no earthly power will prevent a tent from being hot in June and July. It is at best only an unavoidable makeshift.

For the most favourable display of flowers there should be a substantial building, abundantly lighted like a picture gallery; and until such a one arises, as a worthy and well-deserved adjunct to the possessions of the Royal Horticultural Society, we shall have to be contented with, and even thankful for, the temporary tent and the venal Drill Hall. Meanwhile, we shoot our arrow of suggestion into the air, hoping that its flight may perchance project its harmless point into the heart of some patriotic millionaire with horticultural sympathies, and may guide his thoughts into such a desirable channel for the flowing forth of some superfluous wealth, as might be provided by the presentation and endowment of such a building.

We shall hope to have something more to say on the subject of Rose and other shows before long.—Eds.]

RANUNCULUS LYALLII AT HOME.

[TO THE EDITOR OF "THE GARDEN."]

SIR, Under this heading "E. W." contributes some remarks concerning this handsome New Zealand flower in your number of October 7 last. Two or three of his remarks evoke these comments. He says, "Reliable information concerning it seems of the vaguest description." About two years ago I sent you a note, which you published, giving such reliable information as one who has often seen it at Oira Gorge and other places in our Southern Alps, and who has grown it for many years, might be expected to furnish. Yet, notwithstanding this, the notes which have recently appeared in your pages show that growers have either overlooked or disregarded the information I supplied. "E. W." speaks doubtfully about this plant being an annual growing in marshy situations and in stony ground. I may, perhaps, be allowed to say that the plant is not an annual, does not grow in marshy situations, nor is stony ground a necessity. It grows best in a peaty soil with abundant moisture and thorough drainage. What I have to contend with in my garden is that the tuberous root gradually rots away, which I attribute to the circumstance that instead of the soil being frozen, as it must be in winter in the mountains, it is then too wet, and is too much baked in summer. My plants often start growing in winter in a half-hearted sort of way instead of coming away with a strong growth in the spring. If any of your readers wish further information, I would refer them to my former note. Perhaps you could append the exact date.

Dunedin, N.Z.

[The note appeared on p. 164, vol. liii.—Eds.]

WINTER ACONITES NOT FLOWERING.

[TO THE EDITOR OF "THE GARDEN."]

SIR,—“W. P.” inquires the reason of the plants not flowering year by year. If the plants are really in full leaf as stated, and indeed they should be so now, it is obviously a case of overcrowding, for which lifting and replanting is the remedy. This, however, cannot well be done until the foliage is again mature and ripened off. It will be advisable not to replant the tubers at once, but to give them a good rest of at least six weeks in quite dry earth, or even spread out thinly in shallow boxes. This simple, though very welcome, flower is rarely seen to good advantage. This is as frequently due to

deterioration of the tubers as it is to uncongenial soils. Deterioration is brought about in many ways; for instance, many amateurs in wishing to extend the culture of this plant in the garden will lift a few clumps for transplanting just as the leaves are beginning to decay. These clumps may or may not be divided into one or more parts, and here is the beginning of the end. If divided, they reap for a time the advantages that fresh soil and position impart. If not freely divided, then deterioration is always more certain and more rapid. This is due to the way the tubers cluster in an established root clump, and if carefully examined it will be seen that only a few of the outer tubers in the clump flower at all. Each year this becomes worse.

Hampden Hill.

E. H. JENKINS.

STERNBERGIA COLCHICIFLORA.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Has any reader of THE GARDEN any knowledge of the above plant? It was introduced more than sixty years ago by the Hon. W. F. Strangways, and illustrated in the *Botanical Register*, No. 2008. In appearance it is not unlike a *Merendera*, but yellow instead of purple. It is an autumnal bloomer.

T. H. ARCHER-HIND.

FRANCISCEAS.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Can any of your readers give me information about growing these beautiful flowers? I have two large flowering plants and one of the smaller variety. They "flower themselves to death," as the gardener says, but make no growth and are very leggy. They are kept fairly cool, but go into the warm house to set the buds, and when flowering are placed in the conservatory.

M. E. H.

[These plants are predisposed to flowering most profusely. In the cases of both the large and small flowering varieties, the method to adopt in order to obtain good wood growth is to pick off the flower-buds and place the plants in a warmer and more congenial atmosphere. Treat them as if they were Indian *Azaleas* after flowering so as to secure the same ends. The "leggy" appearance may be overcome by judicious training and tying, bending the shoots down and around the stakes; by this means back growths may be induced to break forth. The best soil for the Francisceas is turfy fibrous peat and sand, potting firmly, but not too often. We are glad to see that these charming plants are not altogether lost sight of. The fragrance alone of *F. uniflora* (syn., *F. Hopeana*) is quite sufficient to recommend it. Eps.]

CROCUSES IN MACEDONIA.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—The illustration of "Crocuses under a Beech tree" and the editorial note thereon reminded me of a never-to-be-forgotten picture which I saw last year during the month of March in Macedonia. A friend and I were riding from Piriend to Pristina, accompanied by zapchieks, or Turkish mounted police, to whom we had in vain endeavoured to give the slip. After reaching the summit of a range of hills, and just as we were beginning to descend the further side, we entered a dense wood of magnificent old Beech trees. There was truly enough "no fresh sward or Bramble tangle, or brake of other bushy growths," but the ground was yellow with thousands upon thousands of Crocuses, flourishing "in the carpet of dry rotting leaves." We stopped our horses to feast our eyes upon the glorious colour. My friend observed, after a moment's silent admiration, "Why, I thought that no flower would grow under Beeches!"

It may be worth mentioning, however, that although pretty blue clumps of *Scilla bitolia* were common enough on the treeless hill-top, growing there side by side with and in greater luxuriance than groups of Crocuses, they did not share the partiality which the latter conceive for the shelter of the Beeches; only a few isolated specimens of them were to be seen in the forest itself.

ROLLO MEYER.

SCENTED-LEAVED GERANIUM LADY SCARBOROUGH.

[TO THE EDITOR OF "THE GARDEN."]

SIR.—Will any reader of THE GARDEN who successfully grows that beautiful sweet-scented Geranium named Lady Scarborough tell me how to grow it well, giving details as to propagation, soil, summer and winter treatment, and the temperature it should be kept in during the winter months, as I find that it is a difficult plant to grow in the same way as the zonal varieties? P. J.

[The variety in question is not by any means one of the easiest to keep in the best of health. It is not alone in this respect, for there are a few others belonging to this attractive section which are quite as uncertain as regards their constitution. We have found the best remedy to

be to grow such as Lady Scarborough as if it were a Cape Heath or New Holland plant, and never to adopt the same method of culture as that accorded to the show or fancy sections, or, on the other hand, to the zonal Pelargoniums. By potting firmly from the cutting stage in good loam and leaf-soil, never attempting to excite growth unduly by the use of liquid or artificial manures, as in the case of other Geraniums, it is possible to keep the delicate growers in a much better state of health. It should not be inferred by this that no stimulant is advisable, but when applied the plants should be well rooted in their pots, and then only a very occasional and weak application is recommended. Instead of the pruning, as in the case of show or fancy Geraniums, a regulation of the growth by pinching, as in the case of Cape Heaths, is the better plan to adopt. In fact, in every respect, excepting the soil, treat them as if they were Cape Heaths. It is always a good plan to have a fresh batch of cuttings struck every season in order to be able to dispense with the sickly ones. Caution is also necessary not to overpot these delicate growers. One of the most fragrant (and a charming plant when in flower) is Countess of Devon; it is a variety but little known, but well worthy of extended notice. The only drawback to its culture is its rather delicate constitution. Lady Scarborough may be propagated in the spring in a slight warmth, or in the summer when the wood is well ripened the same as show Geraniums are treated. In the summer thorough exposure to light and air is essential. The greenhouse during the winter is quite warm enough. Eps.]

Hibbertia dentata. This is a delightful climbing plant for a small greenhouse, as it does not need much space for its development, and not only does it bloom during the first three months of the year, but its young foliage is also very attractive at all seasons, being of a bronzy red tint. The saucer-shaped flowers, about a couple of inches in diameter, are of a bright yellow colour. T.

NEW AND RARE PLANTS.

SOME NOTES ON NEW PLANTS.

The following new plants are announced by Herr Max Leichtlin:

Aster Fendleri (A. Gray).—A native of North America. A low-growing species of the group of Ericoideae, with much the aspect of *Diplopappus linearifolius*, with violet flowers.

Asclepias Hallii (A. Gray). Flowers with a greenish white corolla and purple lobes. In appearance this much resembles *A. Sullivantii*. It is found near Denver, on Upper Arkansas River.

Onopordon brachiatum. A native of Pisidia. This is a fine species with rose-coloured flowers, with a thick white down over the stems or branches.

LIATRIS GRAMINIFOLIA VAR. DUBIA IN HERR MAX LEICHTLIN'S GARDEN AT BADEN-BADEN.

Monardella mucronata (A. Gray).—This is figured in 100th volume of the *Botanical Magazine* on plate 6270, and has bunches of tubular scarlet flowers.

Aconopsis grandis. This is a very fine specimen found only in Western Sikkim, but plentiful there. The flowers are solitary like those of *M. simplicifolia*, figured in Catheart and Hooker's work, and are 5 inches in diameter and of very deep blue colour. It is quite one of the finest of the Himalayan species. W. E. GUMBLETON.

Liatris graminifolia var. *dubia*. This genus contains several very beautiful species, such as *pseudostachya*, *graminifolia*, *scariosa*, *magnifica*, *elegans*, and *punctata*, which are all welcome garden plants, their bright-coloured flowers having

a long duration, and, notwithstanding a certain stiffness, they have a graceful appearance. I find the best of the tribe is *L. graminifolia* var. *dubia*. From a full-sized root emerge four to six stems 5 feet to 6 feet in height, clothed half way up with grass-like bright green foliage, the upper 2 feet showing a dense, well-furnished spike of bright deep purple flowers, which last about three weeks. They are at their best in September.

Honour to whom honour is due! I do not wish to adorn myself with others' plumes! Referring to the article on p. 156, I beg to state that I am not the raiser of *Gladiolus princeps*. It was raised by my friend, Dr. W. van Fleet, and I have only been instrumental in the case by furnishing the materials to effect the cross. The female parent is *G. cruentus*, and the male a *gandavensis* variety. *Balkan-Balkan*.
MAX LEICHTMAN.

BOOKS.

Bulletin of Miscellaneous Information, Kew.—We regard the books issued occasionally from the Royal Gardens, Kew, as most important contributions to the horticultural and botanical library. This bulletin is a "list of published names of plants introduced to cultivation from 1876 to 1896," and is undoubtedly a guide that everyone should possess who is interested in the nomenclature of plants. It is a trustworthy reference, of value to the private cultivator as well as the nurseryman. In the preface by the director it is mentioned that "the new plants of 1876 to 1885 were catalogued for 'The Gardener's Year Book' by Mr. N. E. Brown, F.L.S., an assistant in the herbarium of the Royal Botanic Gardens, as unofficial work. He proceeded on a definite plan, which has been continued since. It was, therefore, considered advisable in preparing the present list to start with the new plants of 1876. The lists published in the Kew bulletin are now prepared as routine work by the staff. In addition to species and well-marked varieties, hybrids, whether introduced or of garden origin, have been included where they have been described with formal botanical names. Mere cultural forms of well-known garden plants are omitted for obvious reasons. In every case the plant is cited under its published name. These are largely provisional and often wildly incorrect. When first introduced into cultivation the merit of many new garden plants depends solely on their foliage. Their true botanical affinities cannot be ascertained till they flower, and in some cases many years may elapse before this takes place. A striking instance is afforded by *Talisia princeps*, now known to belong to Sapindaceæ; it had previously passed in gardens under the names of *Theophrasta pinnata* (Myrsinaceæ) and *Brownea princeps* and *B. erecta* (Leguminosæ). . . . The total number of plants catalogued for the twenty-one years which is covered amounts to 7600. The majority of the actually new plants included have been derived from the United States, Colombia, the Malayan region, and the Polynesian Islands, all areas known to be rich in species and still imperfectly explored botanically. The orders most largely represented are all monocotyledonous; they are Orchidaceæ, Liliaceæ, and Araceæ. This is, however, only significant as representing the present drift of horticultural taste. The two first are especially popular in the British Isles for the sake of their flowers, and the latter on the Continent for their foliage." The director also adds: "As an index to the horticultural literature of recent years it is believed that it will be found of practical utility." Of this we feel assured.

The Hop.—This is an excellent work, dealing thoroughly with the plant from all aspects, and the author, the editor of the *American Agriculturist*, has not been content with regarding the Hop from the American standpoint, but obtained contributions from various countries, including

Britain. It is full of illustrations, the majority interesting, though not always reproduced in the best way. With regard to this country the author says, "About two-thirds of the usual Hop area is confined to Kent, the other counties being, in order of importance, Hereford, Sussex, Worcester, Hants, and Surrey. Following the period of high prices, the English crop reached a total extent of 70,000 acres in 1886, but has steadily declined to about 50,000 acres during the closing years of the century."

SOCIETIES.

NATIONAL DALLIA SOCIETY.

WITH the view of drawing attention to varieties of the best Cactus type (as distinguished from the many so-called decorative Dahlias), the committee have drawn up a list of Cactus Dahlias. The list is subject to annual revision, and for the year 1900 is as follows:—

CACTUS DALLIAS.

Alfred Vasey	Lady Penzance
Arachne	Laverstock Beauty
Augustus Hare	Lucius
Bertrice	Mme. Medora Henson
Bridesmaid	Magnificent
Britannia	Major Weston
Capstan	Mary Service
Casilda	Maurice S. Walsh
Charles Woodbridge	Mayor Tuppeney
Cinderella	Mrs. Barnes
Comtess of Gosford	Mrs. Carter Page
Comtess of Lonsdale	Mrs. J. J. Crowe
Cycle	Mrs. John Goldard
Ebony	Mrs. Leopold Seymour
E. J. Deal	Mrs. Saunders
Elsie	Mrs. Wilson Noble
Emperor	Night
Ethel	Ranji
Falka	Regulus
Fantasy	Starfish
Finsler	Stella
Green's White	Sybil
Harmony	The Clown
Harry Strudwick	Tillie
Innovation	Vincetom
Island Queen	Viscountess Sherbrooke
J. F. Hudson	Wm. Fresseder
Keynes White	Zephyr

THE OFFICIAL CATALOGUE

of the National Dahlia Society, issued during the summer of 1898, contains an account of the Dahlia: its bibliography, selected lists of the best varieties of each type (show, fancy, pompon, Cactus, decorative and single Dahlias, the latter grouped as self, fancy, Tom Thumb, and Cactus varieties), together with an alphabetical list, with name of raiser and date of introduction of Dahlias of all sections at present in general cultivation in Great Britain. Selections of varieties which make an especially effective display in the garden are given, as well as of those most suitable for exhibition.

N.B. A supplement has been prepared by a sub-committee during January, 1900, and contains revised selected lists, which are particularly necessary in the case of the rapidly developing Cactus varieties.

HAMPSTEAD HEATH PROTECTION SOCIETY.

THE third annual general meeting took place on March 1 last. Letters were read from Mr. Ernie Hoare, M.P., Sir S. Hoare, M.P., Mr. G. D. Leslie, R.A., and Mr. David Murray, A.R.A.

Mr. E. E. Lake, the chairman, in his opening speech mentioned the interest taken in the preservation of the natural aspect of Hampstead Heath as a heath, not a park, by the late Duke of Westminster.

Mr. H. F. Pooley, hon. secretary, spoke of the necessity of stopping any shooting of rubbish on the Heath. The London County Council had agreed that this is to be absolutely forbidden, and had ordered the removal of some mould and clay placed on the "Horse Ring" on the East Heath. The Parks Committee had thanked the secretaries for informing them of cinders being deposited on the East Heath, and assured the society that they are "most desirous that nothing shall be done to interfere with the amenities of the Heath."

Mr. Basil Champneys, in moving the election of Lord Mansfield as patron of the society, spoke of the loss that the public had sustained by the death of the late Duke of Westminster, who helped so many good causes. He reminded his hearers of the Duke's generosity on the occasions of the laying of Parliament Hill Fields and of Golders Hill for the public. He congratulated the society on having a neighbour and helper in Lord Mansfield.

Col. Grant Gordon, in seconding, mentioned amongst other subjects the great importance of the proper treatment of trees. In Scotland, he said, forestry was considered as an art and deeply studied.

Mr. Figgis said that there was a widespread interest in our beautiful Heath. Many of the London County councillors had taken a great deal of trouble about the proper treatment of it. As an example, he mentioned that as he was crossing the summit of the Heath at half-past eight one morning, he was hailed by Mr. John Burns, M.P., L.C.C. "Hallo! What are you doing here?" said Mr. Figgis. "Oh! I have come up to see how you are going on here, and whether the Heath is all right," said Mr. Burns.

Other interesting references to the Heath at the meeting are referred to on page 193.

ROYAL HORTICULTURAL SOCIETY OF IRELAND.
THE spring show of this society will be held in the Royal University Buildings, Dublin, on April 11, and promises to be the finest display for many years.

SHERBROOKE HORTICULTURAL SOCIETY.

WE have received the splendid schedule of prizes offered at the forthcoming shows of this society. The spring display will take place on April 4 next, and the 26th annual floral fête on August 22 and 23, when prizes to the amount of about £1000, with gold and silver medals, &c., will be offered.

BRISTOL GARDENERS' ASSOCIATION.

THE usual fortnightly meeting of the society was held on Thursday, 8th inst. A large attendance was presided over by Mr. Charles Lock. Mr. R. Stewart, Sneyd Park, provided the paper on the subject of "Peaches and Nectarines." He disclaimed at the outset any intention of dealing with the culture of the fruits in the open air, and confined his remarks to orchard-house culture. He described the structure he thought most suitable, the method of preparing the borders for planting, the soil best suited to the plants, and the time and manner of planting. He also gave a good deal of information respecting the pruning and training of trees, root pruning, dislodging, and thinning of fruit also, urging care in watering, that the trees may never get quite dry on the one hand, or very wet on the other. A good discussion followed, and Mr. Stewart was accorded a hearty vote of thanks on the motion of the chairman.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

THE usual monthly meeting was held at 5, St. Andrew Square, Edinburgh, on the 6th of March. Mr. D. P. Laird, Vice-president, in the chair. There was a good attendance. Unfortunately, Mr. Arnott, the well-known expert on bulbs and hardy plants, who had promised a paper on the Crocus, was unable to be present through illness, but his able and elaborate paper was well read by the secretary, Mr. R. Laird. Mr. Arnott plunged at once into his subject, on which he has long been an authority, and fortified himself by references to Dean Herbert, Mr. Maw, Mr. Baker, as well as the 16th volume of the *Gardener's Chronicle*.

"The Crocus, especially the Safron Crocus (*C. sativus*), has long been cultivated. Crocus sativus has a literature of its own, in respect that it has been the subject of works devoted to it, just as the genus as a whole has received full treatment at the hands of Mr. George Maw, whose monograph of the genus is likely to be ever looked upon as a noble memorial of the author's research and perseverance. Those who have seen it will realise the difficulty one has in following in his footsteps, and in presenting to you a necessarily condensed account of the plant which was so fully treated of by Mr. Maw in that work. As almost everyone knows, the ancients had a simple and convenient, albeit a poetical, way of accounting for the origin of the Crocus as well as that of other flowers. There is more than one version of its first entrance into the realm of flowers. It was said to have owed its origin to the youth named Crocus whose love for Smilax was rejected by that fair dame, and who was changed by the gods into a flower to signify unrequited love.

"However ready we may be to smile at the apparent childishness of these fancies of the ancients, yet we feel that they give interest to our glowing Crocus, even if the traditions and fables mostly refer to the Safron Crocus of autumn, and not to the flowers of spring with which we are most familiar." Mr. Arnott then gave lengthy and interesting poetical references to the flower.

Mr. George Maw says the centre of the area of Crocus distribution roughly centres round the Mediterranean and Black Sea coasts. The same authority rightly says that the district which includes Greece, the Greek Archipelago and Asia Minor may be called the metropolis of the genus. The most western species known to him was *C. clusii* in Portugal; *C. alatavicus*, the most north-easterly, is from the Ala-tan Mountains of Central Asia. Since his various writings were compiled a new habitat for the Crocus was found in Afghanistan by the discovery of *C. speciosus* Aitchisonii, which represents a Crocus that is apparently rather widely spread.

Then Mr. Arnott wrote of the botany of the Crocus, and said that those who wish to master this should turn to volume 16 of the *Gardener's Chronicle*, where the subject is exhaustively treated by Mr. Maw. Dean Herbert and Mr. Baker are also great authorities on the subject.

"At this season we naturally think most of the Crocus of spring, which delights us with its beauty and its brilliant or quiet colouring when early spring appears. I sometimes think what a glorious effect could be produced in the beautiful Princess Street Gardens by a free use of the Dutch Crocuses. They would in no way be incongruous even with those rocks and that grey old castle which tower above the gardens and this historic city which is so dear to every Scotsman worthy of the name. They would give the passers-by a gleam of that floral beauty which has so powerful an elevating influence.

"It is needless to expatiate on the beauties of the best known of these Dutch Crocuses. In addition to those from Holland, which are so plentiful everywhere, there are some pretty varieties, such as George Maw, which is white, with a golden band and peach segment; Leedsii, which has small flowers, purple, tipped with white; which reminds one of the Dutch variety known as Ne plus Ultra; leucorhynchus, a prettily marked variety, and several others. It always appears surprising to me that it seems to be thought that this Crocus is not susceptible of further improvement. I think we could do with more substance in some of the flowers, and we might not only raise flowers with new markings or tints, but others flowering earlier or later. In reading an old horticultural magazine lately I came across an article by the late Mr. T. Francis Rivers, in which he spoke of raising Crocuses from
